"Strophanthus is the dried, ripe seed of *Strophanthus Kombe* Oliver or of *Strophanthus hispidus* DeCandolle (Fam. *Apocynaceæ*), deprived of the awns. Strophanthus, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.00,006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog." *U. S.* "Strophanthus Seeds are the dried ripe seeds of Strophanthus Kombé, *Oliver,* freed from the awns." *Br.*

Strophanthi Semina, *Br.;* Strophanthus Seeds; Strophantus, *Fr. Cod.;* Semen Strophanti, *P. G.;* Strophanthussamen, *G.;* Strofanto, *It.;* Estrofanto (Semilla de), *Sp.*

The seeds of the various species of Strophanthus have been used by the African natives as arrow poisons. In 1861 the famous explorer and missionary, Doctor Livingston, described the method of use of poisoned arrows by the tribes on the Shiré River in East Africa near Mozambique. He says, "The poison used here, called Kombi, is obtained from a species of Strophanthus." Sir John Kurt obtained some of the seeds in the neighborhood of Lake Shirwa, from which this poison was prepared. These were identified by Oliver as being derived from a new species which he named *S. Kombe,* and remarked that the plant was closely allied to a species used for the same purpose at Sierra Leone on the west coast of Africa. Seeds of this plant, brought to Europe by a returning missionary named Waller, were studied by Fagge and Stevenson who found them to act as a cardiac poison similar to digitalis. In 1865 a French naval surgeon, Du Bellay, obtained some seeds that were used as arrow poisons in the neighborhood of the Gabun River on the western coast of Africa in the French Kongo, where it was known as Inée or Onaye. It was at first believed that these two poisons were derived from the same plant, but at present it seems that the *S. Kombe* grows solely in East Africa and that those which come from West Africa must be yielded by other species. For information concerning the history of Strophanthus and description of the plant, see monograph by Frazer (*Transactions of the Royal Society of Edinburgh,* 1890, xxxv, Part 4, p. 955). See also under *Acocanthera,* Part II.

There is no fixed principle of agreement in the several pharmacopœias. Meyer (*A. Pharm.,* 1908, p. 51) very correctly states that it is for the pharmacologist and therapeutist to determine the relative values of each of the seeds before it is possible to determine whether one species may be substituted for another. In Germany the seeds of *Strophanthus hispidus* are preferred because of their guaranteed purity. (*B. P. G.,* xviii, p. 284.) On the other hand, the British Pharmacopœia, the French Codex and the Swiss Pharmacopœia confine their official definitions to *S. Kombe.* The U. S. Pharmacopœia alone recognizes both species, the *S. hispidus* being added because of the arguments that have been advanced in this country as to the efficacy of these seeds. The literature in recent years on the question of strophanthus has been quite voluminous. Some of the more interesting articles are the following: Thoms (*Arb. a. d. Pharm. Inst. d. Univ. Berlin,* 1905, p. 74); Gilg (*Ibid.,* p. 59); Pabisch (*Zeit. Oest. Apoth. Ver.,* xlvii, p. 509); Gilg (*B. P. G.,* xviii, p. 284); Hartwich (*Ap. Ztg.,* xxvi, p. 94).

According to Engler and Prantl, there are twenty-eight recognized species of the genus found in Africa and Asia, extending to China, the East Indies, and the Philippines. The commercial drug is often largely composed of the seeds of other than the recognized official species, and may contain the seeds from related genera, especially those of *Kickxia africana* Benth. The seeds of *Kickxia africana* are without hairs, spindle-shaped, not flattened, twisted into an S-like shape, and with the base and the summit of the seed alike in their forms. On cross-section the cotyledons are seen much folded, while those of the strophanthus lie parallel one upon the other. The transverse section of the kickxia seed, when treated with concentrated sulphuric acid, first turns brown, then red, while the seeds of both kinds of strophanthus take on a green color. According to Stapf, the plant represents a new genus and should be known as the *Funtumia africana;* the only other species of the genus, *F. elastica,* yields India rubber.

The seeds of all the species of strophanthus apparently possess hairs that have a characteristic thickened base somewhat resembling those of nux vomica seeds. The tracing of the origin of the seeds is made more difficult by the fact that in Africa seeds from different regions are mixed before shipment. The seeds of *S. hispidus* enter commerce, as do also those of *S. glaber, S. Emini* Aschers and *S. Courmontii* Sacleux (*P. J.,* 1899, lxiii, p. 34). A white woolly strophanthus is said to be yielded by *S. Nicholsoni,* a species first characterized by Holmes (*P. J.,* 1897, lix, 208). *S. gratus* of Sierre Leone also contributes its seeds; also *S. glaber* contains ouabain.

Sharp (*P. J.,* 1912, lxxxviii, p. 159) has found that the seeds of the *S. Courmontii* are about one-fourth as poisonous to frogs as those of the *S. Kombe,* but their physiological effects are of a similar type. The seeds of the *S. Emini* Asch, he found to be almost without action upon the frog's heart. The seeds of the *S. Thalloni* and of the *S. Tarmentosus* A. DC., are also active.

S. hispidus when by itself takes the form of a bush, but usually occurs as a woody climber inhabiting the forests between the coasts and the center of the African continent. It reaches to the tops of the highest trees, coiling on the ground, and hanging in festoons from tree to tree. The stem is several inches in diameter. The flowers are cream-colored, yellow at the base, purplish-spotted above. They are grouped in terminal cymes. The lobes of their gamopetalous corollas are prolonged into very narrow tail-like ends being nine or more inches in length. The fruit, a pair of follicles from 10 to 17 inches long, is ripe in June, and is gathered by the natives, who scrape off the husks (epicarp and mesocarp) before drying, and preserve the more leathery internal inner covering (endocarp) with the enclosed seeds; hence the pods as they appear in commerce are smooth and of a tawny color. The seeds themselves are covered with long comose hairs, which, being deciduous, are apt to be lost before the escape of the seed from the pod. In preparing the arrow poison, the natives are said to pound the seeds deprived of their hairs to a pulp, add the adhesive sap of another plant, and simply smear the mixture for six inches along the point of the arrow. Game wounded by such an arrow is said to be rarely able to move a hundred yards, and the flesh is eaten without bad effect. Karsten has examined the *root* of *Strophanthus hispidus* and found that it contained *trigonelline, choline* and *strophanthin* in such small proportions that it will probably never be commercially valuable. (*B. P. G.,* 1902, 12, 241.)

Strophanthus occurs in commerce either in pods or as clean seeds. Helbing states (*P. J.,* March, 1887) that he has found the seeds to constitute about 37 per cent., the pod (endocarp) 37 per cent., and the hairs about 25 per cent., and says that the quality of the pods may be determined by examining the color of the pappus. If this is white and bright, the seeds and pods are in good condition.

Description and Physical Properties.—"*Unground Strophanthus Kombe.*—Oblong-lanceolate, flattened and obtusely edged; from 8 to 25 mm. in length, from 2.5 to 5 mm. in width, and from 0.5 to 2 mm. in thickness; the raphe ridge extending from near the center of one side to the apex; light brown with a distinct greenish tinge; silky lustrous owing to a dense coat of closely appressed hairs; fractured surface whitish and oily; taste very bitter.

"*Unground Strophanthus hispidus.*—Light to dark brown; otherwise resembling *S. Kombe* excepting that it is smaller and with fewer and smaller hairs.

"*Structure.*—Epidermis with numerous, unicellular hairs usually bent and arising in *S. Kombe,* from the center of the surface of the epidermal cell and in *S. hispidus,* from near the radial wall; endosperm of 9 to 30 rows of parenchyma cells; embryo consisting of a short straight caulicle, 2 long plano-convex cotyledons and a small radicle. Endosperm tissue usually colored dark-green with sulphuric acid.

"*Powdered Strophanthus.*—Grayish-brown to dark brown; epidermal cells with thickened, lignified radial walls; hairs slightly lignified and from 0.2 to 0.8 mm. in length, fragments of endosperm and cotyledons with fixed oil, aleurone grains and starch grains, the latter from 0.004 to 0.008 mm. in diameter; prismatic crystals of calcium oxalate in seed coat absent (*Strophanthus Courmontii* Sacleux)." *U. S.*

The seeds of *S. Kombe* are described in the British Pharmacopœia as "oval, acuminate, about fifteen millimetres long and four millimetres broad; flattened, narrow towards the base, which is obtuse; covered with silky appressed hairs; provided on one side with a longitudinal ridge running from the centre to the apex; of a greenish-fawn color. Kernel white and oily; cotyledons straight; endosperm narrow; in the seed-coats not more than an occasional crystal of calcium oxalate. Characteristic odor; taste very bitter. *Sulphuric acid* diluted with one-fifth of its volume of *water* colors the endosperm, and sometimes the cotyledons, dark green (presence of strophanthin)." *Br.*

At present strophanthus seeds are much less mixed than formerly. In 1892 Hartwich classified commercial strophanthus seeds (*A. Pharm.,* 1892, 401), in the following groups: (1) The official products yielded by *S. hispidus* or *S. Kombe,* which contain strophanthin and no crystals of calcium oxalate. (2) Those resembling the official seeds, but of different habitat—viz., Mozambique and Sierre Leone. (3) Those which contain calcium oxalate crystals, but no strophanthin—viz., Senegal, Lagos, Niger, German East Africa, Togoland, and Baol of Senegal. (4) A very hairy seed from the Upper Niger. The hairs vary in color from a silky white to brown; the embryo contains calcium oxalate crystals, but the seeds do not contain strophanthin. (5) Seeds which are said to be glabrous, but possess hairs in the region of the raphe. These include those from Lagos and Zambesi, and contain neither calcium oxalate crystals nor strophanthin. The seeds of *S. gratus* are recommended by E. Gilg as more easily recognized than the others and because it yields strophanthin more readily in crystalline form. (*B. P. G.,* 1904, 90.)

The seeds of *S. gratus* (Wall et Hook.) Franchet. are characterized by their uniform and reliable activity and it has been suggested that they may replace advantageously those of *S. Kombe.* They are obtained from plants growing in Senegal and the Congo, the same region in which *S. hispidus* is found. According to Gilg the seeds are spindle-shaped, being at the bases more or less rounded, although sometimes truncate. In the upper portion, they are sharply angular, sometimes being winged and gradually tapering at the summit. Externally the seeds are of a characteristic yellow or yellowish-brown. They vary in length from 11 to 19 mm., in breadth from 3 to 5 mm., and in thickness from 1 to 1.3 mm. In taste they are strongly and persistently bitter. On the addition of sulphuric acid to microscopic sections the latter are colored reddish or of a rose tint, changing to a deep red or violet. They contain the glucoside, ouabain.

The seeds of *S. Courmontii* Sacleux are 8 to 14 mm. in length, 2.5 to 3.5 mm. in breadth and 1 to 2 mm. in thickness; of a distinctly lanceolate form and decidedly brown color, often with the hairs rubbed off, but having a golden sheen when these remain, while the tint is dull and reddish when they are absent. The ridge on the ventral surface is indistinct and the arrangement of the hairs in longitudinal rows is now as apparent as in the official seed. They also contain crystals of calcium oxalate in abundance, which have been stated by some observers to be entirely absent from *S. Kombe* and *S. hispidus.* The statement of E. M. Holmes (*P. J.,* lxiv) that the seeds of *S. Kombe* and *S. hispidus* give with sulphuric acid a greenish reaction, while those of *S. Courmontii* give a reddish, and *S. elemi* a yellowish-brown changing into reddish, seems not to be absolutely accurate, for while the seed albumen of *S. Kombe* always gives the greenish reaction the cotyledons frequently are mottled with red and rarely give an entirely red reaction. (Perredes.) The strophanthus fruits are gathered when ripe, deprived of their epicarp and mesocarp and occasionally sent into commerce in this condition. More frequently, however, the seeds are separated from the pods, deprived of their awns and shipped both from West African and East African ports.

The sulphuric acid identification test for strophanthus has been improved by Bohrisch (*Ph. Ztg.*, 1918, lxiii, 318) who recommends the following manipulation: Thin cross-sections of the seeds placed on an object glass and treated with ether to remove the fat, are covered with one drop of sulphuric acid, containing ¼ of its weight water. The deep green coloration, indicating the presence of strophanthin, should, especially when some magnification is used, be observable in the endosperm and at least the outer portions of the embryo. When big sections (seeds cut in half) were used, the results of the test were very variable and indefinite. According to Karam Samaan (*C. D.*, 1919, xci, 802), two drops of concentrated sulphuric acid on a slab with 0.1 gramme of ammonium molybdate and a trace of strophanthin or strophanthin-containing residue gives a light brownish-green color which gradually develops into blue after 10 minutes. The intensity of the blue color reaches a maximum in 20 minutes and remains permanent, but may be destroyed instantaneously by addition of concentrated nitric acid.

Assay.—"Prepare a tincture by the official process and proceed as directed under *Tinctura Digitalis.*" *U. S.*

Several methods for the chemical assay of strophanthus have been suggested. These are all based on the principles of the extraction of the total glucosides and conversion into strophanthidin. Lampart and Mueller (*A. Pharm.*, ccli, 609) extract the drug with absolute alcohol, remove the oil from the percolate by means of petroleum ether and decompose the glucoside by boiling with hydrochloric acid.

Heacock (*Brit. and Col. Druggist,* 1911) percolates the drug first with petroleum ether to remove the oil and afterwards exhausts with 70 per cent. alcohol. The alcoholic extract is then partially evaporated, dissolved in an acidulated water, shaken out with ether, and the aqueous portion heated to 75° C. for one hour, and the strophanthidin formed during this period extracted with chloroform.

The Kombe seeds yield from one to two per cent. of glucosides.

Knudson and Dresbach (*J. P. Ex. T.*, 1922, x, 205) have presented evidence to show that the Baljet reaction (see under *Digitalis*) affords a criterion also for strophanthus.

None of the chemical standards are as yet sufficiently developed to be able to replace the biological assay which is official in the *U. S.* (for details of this see under *Digitalis*).

Constituents.—Hardy and Gallois in 1855 described in strophanthus a glucoside, *strophanthin,* and an alkaloid, *inœine.* The existence of the alkaloid has not been confirmed by subsequent investigators. The activity of the drug is undoubtedly due to the glucoside. The studies of Fraser (*A. J. P.*, 1889, 532), Thoms (*B. Chem. G.*, 1898, p. 534 and 1904, p. 104), Feist (*B. Chem. G.*, 1900, xxxiii, p. 2069), Brauns and Closson (*J. A. Ph. A.*, 1913, ii, p. 489) and others have apparently established the following facts: different species of strophanthus contain related but not identical glucosides. Thoms has suggested distinguishing these by the initials of the specific name, as *K-strophanthin* from the *S. Kombe, G-strophanthin* from the *S. gratus, E-strophanthin* from the *S. Emini, H-strophanthin* from the *S. hispidus.* The *G-strophanthin* is identical with ouabain (see under *Acocanthera,* Part II, also under *Reagents,* Part III). *S. Kombe* contains two glucosides, the more abundant being amorphous and having twice the molecular weight of the isomeric crystalline glucoside. These glucosides each have the empiric formula $C_{40}H_{56}O_{15}$ and when hydrolyzed yield *strophanthidin,* $C_{27}H_{38}O_7$, and a sugar.

There is evidence that the glucoside from the *S. hispidus* is identical with the amorphous principle from the *S. Kombe* (see Pomeroy and Heyl, *A. J. P.*, 1922, xcv, p. 479) although the matter cannot be considered definitely established.

Rowe (*T. G.*, 1917, xxxiii, p. 536) has shown that there is great difference in the toxicity of these various strophanthins. Ouabain is approximately twice as poisonous as *K-strophanthin,* although the relations vary greatly according to the animal and the method of administration employed. According to Tiffeneau (*B. Sc. Pharm.*, 1922, xxix, p. 68), the crystallized *K-strophanthin* is about one and one-half times as active as the amorphous variety.

For a discussion of the analytical differences of the several strophanthins and for the differentiation of strophanthin and ouabain, see *Pharm. Zeit.*, 1915, 159 and 174; and *J. P. C.*, 1921, 161.

Sieburg (*B. P. G.*, 1911, xxiii, 278) has found an acid saponin in *S. hispidus* which he calls *strophanthic acid.*

Uses.—As was first shown by Thomas R. Fraser (*J. A. P.*, vii, p. 141), strophanthus belongs to that group of cardiac poisons of which digitalis is the type. Its effects upon the circulation are so similar to that drug (see page 408) that it is only necessary to note the points of difference. Strophanthus is somewhat more rapid in its action and decidedly less permanent than digitalis; it causes relatively less reduction of the pulse rate and is generally believed to have less influence on the vasomotor mechanism. It appears to be absorbed from the intestinal tract with much less regularity than digitalis and therefore is less certain in its effects. Besides its action upon the circulation, strophanthus has a marked influence on intestinal peristalsis, according to Magnus (*A. G. P.*, 1905, cviii, p. 1), causing increased peristalsis and tone and under certain conditions tetanic spasm of the intestines. Probably because of this action it frequently produces diarrhea when used clinically. According to the early researches of Fraser it exercises a similar influence on all forms of muscle tissue including voluntary muscles. It is by some believed that strophanthus has a direct stimulating effect upon the kidney and is superior to digitalis as a diuretic, but the evidence in favor of this view is far from convincing. While it possesses some local anesthetic powers it is so highly irritant that it is practically unavailable for this effect.

Strophanthus is used in medicine solely for its influence on the circulation, especially in cases of *chronic heart weakness.* It is of value in exactly the same class of cases in which digitalis is employed and, although more likely to cause digestive disturbances, is frequently useful as an alternative or adjuvant to that drug. By some it is believed to be especially indicated in those cases complicated with dropsies, because of a belief in a greater diuretic power. In cases of threatening urgency the effects of strophanthus upon the circulation can be obtained almost immediately by means of the intravenous injection of its active principles (see *Strophanthinum*).

The question of the relative variability of potency in strophanthus as compared to digitalis cannot as yet be definitely answered. Although certain German investigators have claimed that strophanthus is more subject to wide range in power, Hatcher and Bailey (*J. A. M. A.*, 1909, lii, p. 5) have found that the tincture of strophanthus is much more uniform in this country than the tincture of digitalis.

Dose, of strophanthus, one-fourth to one grain (0.016–0.065 Gm.).

Off. Prep.—Extractum Strophanthi, *Br.;* Tinctura Strophanthi, *U. S. Br.*

STRYCHNINA. N. F., Br.

STRYCHNINE Strych.

"An alkaloid ($C_{21}H_{22}O_2N_2 = 334.30$) obtained from nux vomica, and also obtainable from other seeds of the *Loganiaceæ.*" *N. F.*

"Strychnine, $C_{21}H_{22}N_2O_2$, is an alkaloid, obtained from the seeds of Strychnos Nux-vomica, *Linn.*, and other species of Strychnos." *Br.*

Strychnia, Strychninum, ***Fr. Cod.;*** **Strychnin,** ***G.;*** **Stricnina,** ***It.;*** **Estricnina,** ***Sp.***

The U. S. X has omitted this base although two of the salts are recognized. It has been admitted to the N. F. No process for extracting strychnine is official as it can be made profitably only by the manufacturing chemist on a large scale. (See *U. S. D.*, 17th ed., p. 1295.) The method employed is, in brief, as follows: The powdered nux vomica is mixed with slaked lime and water added to make a paste which is then dried and exhausted with chloroform. From this the alkaloids are extracted by dilute sulphuric acid; this aqueous solution is then alkalized with ammonia and the precipitated alkaloids extracted with 25 per cent. alcohol which dissolves the brucine but leaves most of the strychnine. The latter is then purified by recrystallization.

J. F. Molyn proposed, previously to the extraction of strychnine, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the strychnine and brucine igasurates, producing with these bases very soluble lactates. For the particulars of this process, see *A. J. P.*, xix, 99, and for other processes see *U. S. D.*, 14th ed., p. 1456.

The bean of St. Ignatius yields strychnine more easily and more largely than nux vomica.

Description and Physical Properties.—As usually found in commerce, strychnine is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or rhombic prisms with pyramidal summits.

"Strychnine occurs in colorless, transparent, prismatic crystals, or as a white, crystalline powder; odorless, permanent in the air. *Great caution must be used in tasting it and then only in very dilute solutions* which are exceedingly bitter. One Gm. of Strychnine dissolves in 6420 cc. of water, 136 cc. of alcohol, 5 cc. of chloroform, and in 180 cc. of benzene at 25° C.; also in 3100 cc. of boiling water, and 34 cc. of boiling alcohol; very slightly soluble in ether.

"Its saturated solutions are alkaline to litmus and are lævorotatory. Sulphuric acid containing 1 per cent. of ammonium vanadate produces with Strychnine a deep violet-blue color, changing to a deep purple, and finally to a cherry-red. A solution of about 0.1 Gm. of Strychnine in 2 cc. of sulphuric acid is not more than pale yellow (*readily carbonizable organic impurities*), but on adding a fragment of potassium dichromate, a deep blue color is momentarily produced, changing to deep violet, then to purplish red, cherry-red and finally to orange or yellow. Incinerate about 1 Gm. of Strychnine: not more than 0.1 per cent. of ash remains. One cc. of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine, may produce a yellow, but not a red or reddish color (*brucine*)." *N. F.*

"Colorless, transparent prismatic crystals, permanent in the air. Very slightly soluble in *water,* but sufficiently soluble to impart an intensely bitter taste; soluble in about 150 parts of *alcohol* (90 per cent.). *Sulphuric acid* forms with it a colorless solution which, on the addition of *nitric acid,* acquires not more than a faint pink color (limit of brucine). When a small fragment is dissolved in 2 or 3 drops of *sulphuric acid* on a white porcelain plate and a crystal of *potassium bichromate* is slowly moved through the solution, an intense violet color is produced, passing to red and yellow. No appreciable ash." *Br.*

Strychnine is so extremely bitter that it is perceptible to the taste in the proportions of one part in 700,000 of water. Although it contains two nitrogen atoms, strychnine is a monoacidic base. It has a melting point of 268° C. and an optical rotation of –132.07 in alcohol. When warmed with sodium ethoxide it takes up a molecule of water forming *strychninic acid* which is related to betaine. For account of the efforts to determine the chemical structure of strychnine see Henry, *Plant Alkaloids*, 1924, p. 182.

The identifying tests for strychnine often play an important part in forensic chemistry in connection with cases of suspected strychnine poisoning. Many references to the older tests, most of which have been found to be unreliable, will be found in *U. S. D.*, 20th ed., pp. 1072 and 1073.

The official sulphuric acid potassium dichromate reaction first discovered by Otto in 1839, has not been superseded as an identifying test, when other corroborative tests are positive and the suspected substance has been carefully tested to preclude the possibility of its being a mixture of other alkaloids, which can be done by the use of solvents. J. U. Lloyd in his novel "Stringtown on the Pike" used in an interesting manner a color reaction which he had discovered that produced a color which might deceive some who were working on a toxicological investigation in strychnine poisoning. *Lloyd's reaction* consists in adding sulphuric acid to a mixture of 1 part of hydrastine and 4 parts of morphine and adding a little potassium dichromate in the manner in which the color test for strychnine is made; colors are produced which somewhat resemble those given by strychnine, but a careful toxicologist could not be deceived. A controversy ensued upon the announcement of the reaction, participated in by Williams, Mayer, Wangerin, Wharton, and others, the result of which proved that the value of the official color test of strychnine had not been seriously assailed. (See *D. C.*, 1901, 28, 48; *Proc. N. Y. State Pharm. Assoc.*, 1901, 252; *Amer. Drug.*, 1903, 66.)

The adulterants and impurities reported in strychnine in the older literature are no longer of importance. The present methods of manufacture assure a pure alkaloid, and the Food and Drug Laws protect against the flagrant adulterations reported at a time when strychnine was largely used by trappers in the pioneer days of the West. For methods of distinction from brucine see *Nux Vomica.*

Incompatibilities.—Strychnine is precipitated from its solution by the ordinary alkaloidal reagents such as carbonates, tannic acid, etc. The most important incompatibility, however, is with the halogenic acids. It should never be prescribed in liquid form in combination with bromides, iodides, or chlorides, for fear of forming the insoluble strychnine hydrobromide, hydriodide, or hydrochloride. Several cases of poisoning have occurred through neglect of this precaution. A. B. Lyons (*A. J. P.*, Oct., 1877) records a case of poisoning through the patient's receiving in the last dose the greater portion of the strychnine hydrobromide, which had crystallized out.

Uses.—Strychnine is a stimulant to the whole central nervous system. The effects upon the brain are usually not well marked but in some individuals wakefulness often follows its use and the increased acuity of the special senses is further evidence of its stimulant action upon the cerebrum. The most direct symptom caused by strychnine is violent convulsions. These have been shown by McGuigan and Becht (*J. P. Ex. T.*, 1916, viii, 143) to be due to a simultaneous stimulation of both motor and sensory ganglia of the spinal cord. In the medulla the centers which show a special evidence of the stimulating effect of strychnine, are those governing respiration and vasomotion. While the increase in respiration caused by strychnine is not as great in the normal animal as after some other drugs, it seems to possess an extraordinary power of overcoming the effects of depressant poison. Clinically it is perhaps the most reliable respiratory stimulant which we possess. During the strychnic convulsion there is great rise in the blood pressure This is due in large part to the violent spasm of the muscles and consequent asphyxia, but even when the convulsions are prevented by the previous injection of curare the drug still produces a distinct rise in the arterial pressure, indeed in doses too small to cause convulsions there is still evidence of a stimulation of the vasomotor center. The experiments of Pilcher and Sollman (*J. P. Ex. T.*, 1915, vi, p. 331) indicate that the effect is due largely to an increased irritability of the center so that it responds abnormally powerfully to any exciting influence. Stewart and Rogoff (*J. P. Ex. T.*, 1919, xiii, 95) attribute the rise of pressure to stimulation of the adrenals. The effect of the drug upon the heart is not clearly understood. Although La Franca (*Z. E. P. T.*, 1911, ix, p. 436) found that strychnine increased the irritability and conductivity of the heart muscle the scientific evidence of any direct influence upon the heart is far from convincing. In large toxic dose strychnine causes a paralysis of the motor nerves similar to that produced by curare but it is improbable that this action can play any part in strychnine poisoning in the human being.

The convulsant effects of strychnine naturally suggest its use in *paralysis* but a moment's thought must convince anyone that in most forms of palsies it is incapable of benefit. When the loss of power depends upon the actual destruction of motor cells, as after apoplexy or poliomyelitis, it is evident that the drug can do no good because what does not exist cannot be stimulated. Or when there is a failure in the conducting power of the nerve, as in peripheral neuritis it is equally manifest that excitation of the spinal cells is futile. Indeed in spinal paralyses much harm may be done by irritating the inflamed tissue in the neighborhood of the area of destruction. On the other hand when the paralysis is due to the effect of depressant poisons circulating in the blood, as, for instance, in certain types of *chronic lead poisoning,* strychnine may prove of the utmost value. Like other bitters strychnine improves the appetite and digestion, but it has been enormously misused as a "general tonic." It is to be remembered that strychnine is essentially a stimulant leading to an increased functional activity with an expenditure, rather than a storing up, of reserve power. Such slight tonic effects as it may possess are due to the improved digestion and circulation. There is a common belief among clinicians that strychnine increases the peristaltic activity of the intestinal tract and hence it is frequently added to laxative mixtures, but the experimental evidence on this point is contradictory.

As a circulatory stimulant strychnine is useful in a wide variety of conditions such as *surgical shock, collapse* from hemorrhage, *poisoning* by such depressants as ether, chloroform, or alcohol, and the adynamic stages of *infectious fevers.* In some forms of *chronic heart disease,* especially in *myocarditis,* it seems to be clinically useful. Smith (*J. P. Ex. T.,* 1917, ix, 365) finds that it lessens irritability of the heart and may be of service therefore in extra systoles but is liable to be injurious in other forms of cardiac irregularities. Its value in *chronic bronchitis* in old and feeble subjects is probably also to be attributed to its effects upon the circulation. As a respiratory stimulant it is especially valuable in narcotic *poisoning,* as by *opium* or *chloral.* Strychnine is also asserted to be of much service in toxic *amblyopias,* especially that due to nicotine poisoning.

For ordinary purposes the dose of strychnine ranges from one-sixtieth to one-twentieth of a grain (0.0011–0.003 Gm.) but under many circumstances much larger quantities may be safely administered. Especially when used for its influence upon the circulation is it essential to give large doses. Many of the clinical reports of failure to influence the circulation with strychnine have doubtless been due to too small doses, thus Lucas (*American Journ. Dis. of Children,* 1914, vii) found that it required at least one-tenth of a grain to cause an appreciable change in the blood pressure. While others have reported distinct effects from somewhat smaller dose, the use of one-fortieth or one-thirtieth of a grain with the idea of having any marked influence upon the circulation is a delusion. In many cases it is essential to push the strychnine until marked exaggeration of the reflexes or even twitchings of the muscle affords a warning that the patient is approaching the toxic stage. Newburgh (*A. I. M.,* March, 1915) from studies on cases of pneumonia and typhoid fever concludes that it has no reliable effects on the circulation.

Poisoning.—The symptoms of strychnine poisoning come on usually with great suddenness and violence. Often without warning of any kind a patient falls in a violent convulsion. The convulsions are usually tonic in character, but are interrupted with periods of almost complete relaxation. They involve all the muscles of the body and are brought on by the slightest sensory impulses. During the spasm the body is rigid, usually arched backwards in the position of opisthotonos, the arms flexed, the face drawn into the *risus sardonicus.* Consciousness is not affected except as the result of the asphyxiation. During the period of convulsion the muscles of the chest are so firmly fixed that respiration is impossible and death may occur as the result of asphyxiation. In some cases, however, the fatal termination may be deferred for some hours and finally be the result of exhaustion. The ordinarily fatal dose probably lies between one-half and one grain, although much larger quantities may be recovered from under proper treatment.

In the *treatment* of strychnine poisoning it is to be remembered that the convulsions are of reflex origin and therefore all manipulations which are capable of furnishing the sensory stimulus must be sedulously avoided. For this reason no attempt should be made to empty the stomach; death has occurred during a convulsion brought on by the effort to pass a stomach tube. As a chemical antidote potassium permanganate is probably to be preferred, although Fantus (*J. A. M. A.,* 1915, lxiv) has reported favorable results in the lower animals from the use of Lloyd's reagent (silicated earth), and compound solution of iodine or tannic acid are also of value. The most important therapeutic measure is the control of the convulsions. For this purpose chloroform is probably the most efficient remedy. This drug should be administered to the stage of surgical anesthesia, after which chloral hydrate and potassium bromide may be given to continue the sedative effect. Amyl nitrite is also a useful agent because of the rapidity of its action; during the height of the convulsion, when there is no respiration, 3 to 5 minims may be given hypodermically.

In an investigation of the members of the pyridine series of bases by C. Greville Williams and W. H. Waters (*Proc. Roy. Soc.,* xxxii, p. 162, 1881), they found that β lutidine (dimethyl-pyridine, C_7H_9N) was antagonistic to strychnine and an apparent antidote. When injected into frogs already under the influence of strychnine, it arrested the convulsions; or if given first and then followed by a fatal dose of strychnine, it prevented the appearance of the tetanus. (Blyth, *Poisons, their Effects and Detection,* 1884, p. 319.)

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

STRYCHNINÆ HYDROCHLORIDUM. Br.

STRYCHNINE HYDROCHLORIDE

"Strychnine Hydrochloride, $C_{21}H_{22}N_2O_2,HCl,2H_2O$, is the hydrochloride of the alkaloid strychnine." *Br.*

Strychninum Hydrochloricum; Hydrochlorate of Strychnine, *Br.*, 1885; Chlorhydrate de Strychnine, *Fr.;* Strychninhydrochlorid, Salzsaures Strychnin, *G.*

This salt of strychnine was made official for the first time in the Br. Ph. 1898; it is used in making *Liquor Strychninæ Hydrochloridi.* It is described as in "small, colorless, prismatic crystals. Soluble in 60 parts of *water.* Aqueous solution neutral to *litmus;* taste intensely bitter. Loses from 7 to 9 per cent. of its weight when dried at 110° C. Responds to the tests enumerated under 'Strychnina,' and yields the *reactions* characteristic of chlorides. No appreciable ash." *Br.*

In its physiological and therapeutic action, strychnine hydrochloride is equivalent to strychnine.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

Off. Prep.—Injectio Strychninæ Hypodermica, *Br.;* Liquor Strychninæ Hydrochloridi, *Br.*

STRYCHNINÆ NITRAS. U. S.

STRYCHNINE NITRATE Strych. Nit.

"The nitrate [$C_{21}H_{22}O_2N_2.HNO_3$] of an alkaloid obtained chiefly from nux vomica." *U. S.*

Azotate de Strychnine, Nitrate de Strychnine, *Fr.;* Strychninum nitricum, *P. G.;* Strychninnitrat, Salpetersaures Strychnin, *G.;* Nitrato di stricnina, *It.*

Preparation.—This salt may be made by dissolving a sufficient quantity of the alkaloid strychnine in diluted nitric acid until it is neutralized, evaporating the solution and crystallizing the strychnine nitrate.

Description and Physical Properties.—"Colorless, glistening needles or a white, crystalline powder. It is odorless and is stable in the air. *Caution—Strychnine Nitrate is extremely poisonous.* One Gm. of Strychnine Nitrate is soluble in 45 cc. of water, 150 cc. of alcohol, 50 cc. of glycerin, and in 105 cc. of chloroform, at 25° C. One Gm. is soluble in 10 cc. of boiling water and in 80 cc. of alcohol at 60° C. It is insoluble in ether.

"An aqueous solution of Strychnine Nitrate is lævorotatory. Dissolve about 0.05 Gm. of Strychnine Nitrate in 5 cc. of distilled water, add a few drops of ammonia T.S., and extract the liberated strychnine with 5 cc. of chloroform. Evaporate the chloroform to dryness on a water bath, cool, dissolve the residue in 2 cc. of sulphuric acid and add a fragment of potassium dichromate. On gently agitating the mixture, a blue color is momentarily produced, changing to violet, then to purplish-red, and finally to orange or yellow. An aqueous solution of the salt, when superimposed in a test tube, upon diphenylamine T.S., develops a blue color at the zone of contact. Strychnine Nitrate, heated with hydrochloric acid, produces a bright red color.

"A solution of 0.5 Gm. of Strychnine Nitrate in 25 cc. of distilled water requires not more than 0.5 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator. Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of Strychnine Nitrate in 5 cc. of sulphuric acid is not darker than pale yellow (*readily carbonizable substances*). The addition of 5 drops of silver nitrate T.S. to 20 cc. of an aqueous solution of Strychnine Nitrate (1 in 100), acidulated with 2 drops of diluted nitric acid, does not produce an opalescence at once (*chloride*), and no immediate turbidity is produced in 20 cc. of a similar solution by the addition of 5 drops of barium nitrate T.S. (*sulphate*). One cc. of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine Nitrate, may produce a yellow, but not a red or reddish color (*brucine*).

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—Strychnine nitrate has no advantage over the other soluble salts of strychnine.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

Off. Prep.—Syrupus Phosphatum cum Quinina et Strychnina, *N. F.;* Elixir Glycerophosphatum Compositum, *N. F.*

STRYCHNINÆ SULPHAS. U. S.

STRYCHNINE SULPHATE Strych. Sulph.

"The sulphate [$(C_{21}H_{22}O_2N_2)_2.H_2SO_4.5H_2O$] of an alkaloid obtained chiefly from nux vomica." *U. S.*

Strychniæ Sulphas, *U. S.* 1870; Strychninum Sulphuricum, *Fr. Cod.;* Sulfate de Strychnine, *Fr.;* Schwefelsaures Strychnin, Strychninsulfat, *G.;* Sulfato de estricnina, *Sp.*

Description and Physical Properties.—"Colorless or white crystals, or a white, crystalline powder. It is odorless and is efflorescent in dry air. *Caution—Strychnine Sulphate is extremely poisonous.* One Gm. of Strychnine Sulphate is soluble in 35 cc. of water, in 81 cc. alcohol, and in 220 cc. of chloroform, at 25° C. One Gm. is soluble in 7 cc. of boiling water and in 26 cc. of alcohol at 60° C. It is freely soluble in glycerin but insoluble in ether.

"An aqueous solution of Strychnine Sulphate is lævorotatory. Add a fragment of potassium dichromate to a solution of 0.1 Gm. of Strychnine Sulphate in 2 cc. of sulphuric acid. A deep blue color is momentarily produced, changing to deep violet, then to purplish red, cherry-red, and finally to orange or yellow. Sulphuric Acid containing 1 per cent. of ammonium vanadate produces with Strychnine Sulphate a deep violet-blue color, changing to a deep purple and finally to a cherry-red." *U. S.*

For information concerning the chemistry and uses of this salt, see *Strychnina.*

Strychnine Sulphate is incompatible with the ordinary alkaloidal reagents, also with sodium cacodylate, with sodium glycerophosphate, and with the iodides or bromides.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

STYRAX. U. S. (Br.)

STORAX [Liquid Storax]

"Storax is a balsam obtained from the trunk of *Liquidambar orientalis,* Miller, known in commerce as Levant Storax, or of *Liquidambar styraciflua* Linné, known in commerce as American Storax (Fam. *Hamamelidaceæ*)." *U. S.* "Prepared Storax is a viscid balsam obtained from the wounded trunk of Liquidambar orientalis, *Mill.,* purified by solution in alcohol, filtration, and evaporation of the solvent." *Br.*

Styrax Præparatus, *Br.;* Prepared Storax; Styrax Liquidus, Balsamum Storacis, Balsamum Styracis, Balsamum Styrax Liquidus; Styrax liquide, *Fr.;* Styrax, *P. G.;* Storax, Flüssiger Storax, *G.;* Storace liquido, *It.;* Estoraque liquido, *Sp.*

All species of the genus *Liquidambar* as well as those of a related genus, *Altingia,* yield *storax.* The product most valued, however, is that obtained from *L. orientalis* Miller.

The *oriental sweet-gum* (*Liquidambar orientalis*) is a tree from twenty to forty feet high. Its leaves are palmately 5-divided, serrate, perfectly smooth, bright green and shining on the upper and pale on the under surface. The flowers occur in globular, yellowish heads and its fruits are spherical heads of beaked capsules. The tree is a native of Asia Minor, in the southwestern parts of which it forms large forests.

The *L. Styraciflua,* commonly known as the *gum tree* (*Sweet Gum, Alligator Tree, Bilsted*), is one of our most beautiful native trees. It is found along the whole Atlantic coast from Connecticut southward to Central America. When full grown the tree reaches a height of 100 or sometimes even 150 feet. The flowers are apetalous and usually monœcious, the fertile ones being arranged in globular heads and the staminate flowers in conical clusters consisting of numerous small greenish heads. The leaves are palmately 5- to 7-lobed, the lobes being acuminate and finely serrate, star-shaped. There are two varieties besides the type species. The *L. Styraciflua Mexicana* has its leaves 3-lobed instead of 5- to 7-lobed as is common in the northern variety, and in the *L. Styraciflua macrophylla* of Central America the leaves are much larger than the type. The wood is hard and close-grained, of a reddish brown color. The exudate apparently was used by the aboriginal inhabitants of the continent; it was exported to Spain in large quantities in the 16th century for use both as a perfume and as a vulnerary. The resin which is commonly known as *liquidambar* or *copal balsam* or *copalm,* collects naturally under the bark in old trees, being rarely found in those less than 100 years old. Its use was revived during the scarcity of the oriental variety caused by the World War.

Although the sweet gum tree is of wide distribution, at the present time the American Storax is not produced in commercial quantities except in Honduras.

According to the researches of Moeller, storax is a pathological rather than a physiological product; when the young wood is injured secretion reservoirs are formed in which the storax is produced. (*O. Z.,* 1.) In collecting the drug the bark is first heavily bruised, so as to injure the cambium. Injury to the cambium stimulates the formation of numerous reservoirs or ducts in which the balsam is secreted and from which it seeps into the injured bark. After a time the outer bark is removed and the inner bark is scraped off. According to Maltass, this inner bark is first pressed cold in horse-hair bags, after which hot water is thrown over the bags and they are again pressed. Lieutenant Campbell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the article formerly known in commerce as *Storax bark* or *Cortex Thymiamatis.* The formerly known "*Styrax calamitus*" consisted of coarsely ground *Cortex Thymiamatis* mixed with storax. The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

American storax—sometimes known as *Copalm balsam*—varies in consistency from that of thin honey to a soft solid. It is more or less transparent, of a yellowish color, of a peculiar, agreeable, balsamic odor, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker color. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to Jordan (*J. I. E. C.,* August, 1917), the resin of American storax averages higher in cinnamic acid than does the oriental variety. (See also Spokes, *J. A. Ph. A.*, 1920, ix, 1055.)

The *L. formosana* Hance also produces a resin resembling storax which has been analyzed by Tsuchihashi and Qasaki (*J. Soc. Chem. Ind.*, 1919, xxxviii, 646a). *L. Altingia* Bl. (*Altingia excelsa* Noronha), a tree which inhabits a very wide region in Southern Asia, yields a storax-like substance varying in color from white to red, sometimes called *Malay Storax* or *Rasamala Resin.* According to Tschirch and van Itallie, it differs from storax in the presence of benzoic and cinnamic aldehydes, the absence of ether and the small quantities of cinnamic acid in it. *L. storesin* is said also to be known in Eastern markets.

For account of the methods of collecting American storax see *Ph. Rund,* 1895, 57 and Watermyer, *Amer. Perf. and Essent. Oil Review,* July, 1919; Mahood and Gerry, *D. C.*, 1921, lxv, p. 3.

Description and Physical Properties.—" A semi-liquid, grayish to grayish-brown, sticky, opaque mass, depositing on standing a heavy dark brown layer (Levant Storax); or a semi-solid, sometimes a solid mass, softened by gently warming (American Storax). Storax is transparent in thin layers, has a characteristic odor and taste, and is heavier than water. Storax is insoluble in water, but soluble, usually incompletely, in an equal weight of warm alcohol. It is also soluble in acetone, carbon disulphide, and ether, some insoluble residue usually remaining.

" To about 0.5 Gm. of the cinnamic acid obtained in the assay add 5 cc. of diluted sulphuric acid, heat, and add potassium permanganate T.S.: the odor of benzaldehyde is evolved. A portion of the acid recrystallized from hot water melts between 134° and 135° C. Dry about 2 Gm. of well-mixed Storax, accurately weighed, for two hours at 100° C.: the loss in weight does not exceed 20 per cent. Dissolve about 10 Gm. of well-mixed Storax, accurately weighed, in 40 cc. of hot alcohol, filter through counterbalanced filters or a Gooch crucible, and wash the residue with small portions of hot alcohol until the washings are colorless or very nearly so: the residue after drying at 100° C. does not exceed 5 per cent. Evaporate the combined alcoholic filtrate and washings at a temperature not exceeding 60° C., and dry the residue for one hour at 100° C.: a yellow to brown residue of purified Storax remains, corresponding to not less than 70 per cent. of the weight of the Storax taken. The purified Storax thus obtained complies with the following tests: Dissolve about 1 Gm. of the purified Storax, accurately weighed, in 50 cc. of neutralized alcohol, add 0.5 cc. of phenolphthalein T.S., and titrate with half-normal sodium hydroxide: the acid number is from 56 to 85 for Levant Storax and from 38 to 85 for American Storax. Place about 2 Gm. of the purified Storax, accurately weighed, in a 250 cc. flask, mix with 50 cc. of purified petroleum benzin, add 25 cc. of half-normal alcoholic potassium hydroxide, and allow the mixture to stand twenty-four hours with frequent agitation. Then add 0.5 cc. of phenolphthalein T.S. and titrate the excess of alkali with half-normal hydrochloric acid. The saponification value thus obtained is not less than 160 and not more than 200.

" Boil about 2 Gm. of the purified Storax, accurately weighed, with 25 cc. of half-normal alcoholic potassium hydroxide for one hour under a reflux condenser. Neutralize with half-normal sulphuric acid, using 5 drops of phenolphthalein T.S. as indicator, and evaporate the alcohol on a water bath. Dissolve the residue in 50 cc. of distilled water and shake the solution with 20 cc. of ether. Shake the separated ether with 5 cc. of distilled water, add the washings to the aqueous solution, and reject the ether extract. Add to the aqueous solution 10 cc. of diluted sulphuric acid and shake with four successive portions of 20 cc. each of ether. Wash the combined extract with 5 cc. of distilled water, rejecting the water washings, transfer to a flask and distil off the ether. Add to the residue 100 cc. of distilled water, and boil vigorously for fifteen minutes under a reflux condenser. Filter while hot and allow the filtrate to cool to about 25° C.: white crystals of cinnamic acid separate. Filter the cinnamic acid on a Gooch crucible, applying a vacuum towards the end to drain the crystals completely. Repeat the extraction of the residue twice by boiling each time under a reflux condenser, as before described, with the filtrate from the preceding crystallization, and collect the additional cinnamic acid in the same crucible. Finally wash the cinnamic acid with two 10 cc. portions of ice cold water, dry at 80° C., and weigh. The weight of the cinnamic acid thus obtained corresponds to not less than 25 per cent. of the purified Storax taken." *U. S.*

" Brownish-yellow, viscous, transparent in thin layers. Entirely soluble in *alcohol* (90 per cent.) and in *ether.* Odor and taste agreeable and balsamic. Boiled with *solution of potassium chromate* and *sulphuric acid* it evolves an odor of benzaldehyde. Loses not more than 5 per cent. of its weight when heated in a thin layer on a water-bath for one hour. *Acid value* not less than 60 or more than 90; *ester value* not less than 100 or more than 146. Yields not less than 20 per cent. by weight of cinnamic acid when tested by the following process:—Dissolve 2.5 grammes of the Storax in 25 millilitres of *N/2 alcoholic solution of potassium hydroxide,* boil for one hour under a reflux condenser, neutralize with *N/2 solution of sulphuric acid,* remove the alcohol by evaporation, and dissolve the residue in 50 millilitres of *water. Shake* this aqueous solution with 20 millilitres of *ether;* after separation remove the ethereal layer, wash it with 5 millilitres of *water* and add the washings to the aqueous solution, rejecting the ethereal liquid. Acidify the aqueous solution with *diluted sulphuric acid* and shake it with four successive portions, each of 20 millilitres of *ether*. Mix the ethereal solutions, wash with a few millilitres of *water*, transfer to a flask and distil off the ether. To the residue add 100 millilitres of *water* and boil vigorously for fifteen minutes under a reflux condenser. Filter the solution while hot, cool to 15.5° C., and collect on a tared filter the crystals of cinnamic acid that have separated. Repeat the extraction of the residue with the filtrate at least three times, or until no more cinnamic acid is removed. Press the filter paper and crystals between blotting paper, dry in a desiccator over *sulphuric acid*, and weigh. Add to the weight of the crystals so ascertained 0.03 gramme (representing the average amount of cinnamic acid remaining dissolved in the aqueous liquid). The total weight is not less than 0.5 gramme." *Br.*

Storax melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light, spongy, carbonaceous residue. It imparts its odor to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Neumann obtained from 480 grains of storax 120 of aqueous extract, and from an equal quantity 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to rank as a balsam.

Both the Oriental and the American storax are often adulterated with turpentine, Burgundy pitch, castor oil or storax from which the cinnamic acid has been extracted. Such adulterated drug will fail to meet the official requirements especially the cinnamic acid test.

Constituents.—The most abundant constituent of storax is probably *storesin*, $C_{36}H_{55}(OH)_3$, discovered in 1877 by W. von Miller. This is present in two forms, designated respectively *alpha* and *beta*, both free and in the form of a cinnamic ester. These together make up from one-third to one-half of the resin. Storesin is an amorphous substance, melting at 168° C., readily soluble in petroleum benzin. *Cinnamic acid* both in the free state and in the form of esters constitutes an important part of the drug. Free cinnamic acid ranges from 5 to 15 per cent., but Löwe has reported a yield of as much as 23 per cent. Of the cinnamic esters, *cinnamyl cinnamate*, or *styracin*, $C_9H_7O_2.C_9H_9$, is present in the proportion of 5 to 10 per cent. It can be removed by ether, benzene, or alcohol after the separation from the resin of the cinnamic acid; it is insoluble in water, and volatile only in superheated steam. It crystallizes in tufts of long rectangular prisms, which melt at 38° C., but frequently do not solidify readily. By concentrated solution of potassium hydroxide, it is resolved into a cinnamate and cinnamic alcohol (*styrone*), $C_9H_{10}O$, which latter is not present in liquid storax. Of the other cinnamic esters the most important is *phenylpropyl cinnamate* which constitutes some 10 per cent. of the drug. There are present also small amounts of ethyl cinnamate and benzyl cinnamate. There is further found in liquid storax a hydrocarbon, C_8H_8, which exists in the resin as a liquid, and also in a polymeric form as a solid. The former, called *styrol, styrene*, or *cinnamene*, has a sp. gr. of 0.924, and a boiling point of 146° C. It is a colorless, mobile liquid, possessing the odor and burning taste of liquid storax. It has been formed synthetically, being *phenylethylene*, $C_6H_5.CH = CH_2$. When heated it polymerizes into the colorless, transparent solid, *metastyrol*, which, unlike styrol, is not soluble in alcohol or in ether. Lastly, there has been found in liquid storax, about 0.4 per cent. of a pleasant-smelling lævo-rotatory oil of the formula $C_{10}H_{16}O$, and traces of vanillin. For analyses of storax see Tschirch and Von Itallie (*A. Pharm.*, 1901, ccxxxix, p. 506) and Spokes (*J. A. Ph. A.*, 1920, ix, p. 1055).

Uses.—Styrax is a stimulating expectorant and feeble antiseptic, which was at one time used in various *pulmonic catarrhs*, also in *gonorrhea* and *leucorrhea*, but at present is very seldom used except as a constituent of the compound tincture of benzoin. Externally, mixed with two or three parts of olive oil, liquid storax was found by H. Schultze, of Magdeburg, to be very effective as a local remedy in scabies. The bark of the sweet gum tree has been used in the Southern and Western States in *diarrhea* and *dysentery*, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild cherry bark, according to the U. S. Pharmacopœia. The *dose* is a fluidounce (30 cc.) for an adult, repeated after each stool.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Tinctura Benzoini Composita, *U. S., Br.*

SUCCI

JUICES

Sucs végétaux, *Fr.;* **Kraütersäfte Pflanzensäfte,** *G.;* **Zumos,** *Sp.*

Though introduced to professional notice by Squire in the year 1835, and subsequently used by many practitioners, the juices were recognized but once by the U. S. Pharmacopœia (1870). They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and, of course, the uncertainty in operation, of fresh juices themselves varying according to the soil, climate, mode of cultivation, season, and the age of the plant, it may be questioned whether they merit the prominence which has been given them in the past.

SUCCUS LIMONIS. Br.

LEMON JUICE

"Lemon Juice is the freshly expressed juice of the ripe fruit of Citrus Medica, *Linn.,* var. β Limonum, *Hook. f.*" *Br.*

Limonis Succus, *U. S. P. VIII;* Succus Citri; Suc de Citron, *Fr.;* Citronensaft, Limonensaft, *G.;* Succo di limone, *It.;* Zumo de limon, *Sp.*

For account of the botany of lemons see under *Limonis Cortex.* Although so closely related botanically to the lemon, the *lime*—the juice of which was recognized by the N. F. IV under the title of *Succus Citri*—is medicinally very much inferior. For description of lime-juice, see *U. S. D.,* 20th ed., p. 1467.

The juice is the part for which the fruit is most esteemed. It is sharply acid, with a peculiar grateful flavor, and consists chiefly of water, citric acid (from 6 to 10 per cent.), gum and sugar (from 3 to 4 per cent.), and inorganic salts (2.28 per cent.). It sometimes has in it a little volatile oil, derived by pressure from the rind. It is "a slightly turbid, yellowish liquid. Taste sharply acid. Specific gravity 1.030 to 1.040. 20 millilitres require for neutralisation not less than 20 and not more than 25.7 millilitres of *N/1 solution of sodium hydroxide,* corresponding to a proportion of not less than 7 and not more than 9 grammes of citric acid in 100 millilitres. The residue obtained on evaporation, dried at 110° C., yields not more than 3 per cent. of ash. 100 millilitres of Lemon Juice are neutralised by about 11.4 grammes of Potassium Bicarbonate, by about 9.5 grammes of Sodium Bicarbonate, and by about 16.5 grammes of Sodium Carbonate." *Br.*

As lemons cannot always be obtained, the juice is often kept in a separate state, but, from its liability to spontaneous decomposition, it speedily becomes unfit for medicinal use, and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavor unaltered. One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, until a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better if the bottles containing the filtered juice be permitted, before being closed, to stand for fifteen minutes in a vessel of boiling water. Any method of preserving lemon juice which involves the use of heat injures its medicinal virtues, as these depend upon the presence of an unstable vitamin (see Part II). Another mode is to add one-tenth of alcohol and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the aqueous portion and leaves the juice much stronger than before. When used, it may be diluted to the former strength, but though the acid properties are retained, the flavor of the juice will be found to have deteriorated. Bottled lemon juice is frequently found to be preserved with sulphur dioxide, which dissolves in it to form sulphurous acid. The presence of this preservative interferes with some of its pharmaceutical uses and such a product should not be employed for medicinal purposes. Lemon syrup is another form in which the juice is preserved.

The proportion of citric acid in lemon juice varies greatly, ranging from 4.5 to nearly 9 per cent. Huerre reports (*J. P. C.,* 1919, xx, 5) lemon juice to average in each 100 cc.: citric acid, 7 to 7.5 Gm.; malic acid, 0.4 to 0.6 Gm.; sucrose, 0.4 to 0.5 Gm.; invert sugar, 1.8 to 2.0 Gm.; pectin, 0.4 Gm.; and ash 1.6 to 1.8 Gm. Robins (*C. D.,* 1896, 742) found the average yield of citric acid taken from a year's receipts was 35.23 grains in a fluidounce.

Commercial lemon juice often contains salts of organic acids other than citric; salts of inorganic acids; and albuminous, mucilaginous, saccharine, and other indifferent bodies; spirit is frequently added as a preservative, and mineral acids are not uncommonly employed as adulterants, although sulphur dioxide is more commonly used for this purpose and its presence is usually declared upon the label.

The proportion of citric acid in lime juice was required by the N. F. IV to be not less than 5 Gm. nor more than 10 Gm. to each 100 cc.

Uses.—Lemon juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in *febrile affections.* It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as albumen water, barley water, etc., usually administered in *fevers.* Locally applied it acts as an astringent due to its content of citric acid and has been used with benefit in *pruritus of the scrotum,* and in *sunburn.*

One of the most beneficial applications of lemon juice is the prevention and cure of *scurvy.* This disease today is regarded as due to the absence from the food of a water soluble vitamin (see Part II). This antiscorbutic vitamin is found abundantly in lemon juice and in orange juice, but according to Shick, Hume and Skelton (*L. L.,* Nov. 30, 1918) in only small proportions in the juice of the lime. Although it is abundantly demonstrated that this essential foodstuff is not citric acid, Harden and Zilber (*L. L.,* Sept. 7, 1918) have shown that it is rapidly destroyed when the juice is neutralized. The antiscorbutic vitamin is also sensitive to heat; according to Bassett-Smith (*L. L.,* Nov. 13, 1920, 997) heating for three-quarters of an hour to 58° C. greatly diminishes its value, but it is not appreciably affected by 5 minutes' boiling.

Off. Prep.—Syrupus Limonis, *Br.;* Trochiscus Acidi Carbolici, *Br.*

SUCCUS POMORUM. N. F.

FRESH APPLE JUICE Suc. Pomor.

"The freshly expressed juice of sound, ripe, sour apples, the fruit of cultivated varieties of *Pyrus Malus* Linné (Fam. *Rosaceæ*)." *N. F.*

The apple tree (*Pyrus Malus* L., *Malus communis* DC., *Malus Malus* (L.) Br.) probably originated in Europe and western temperate Asia, but has been cultivated from the most ancient times in all civilized parts of the temperate zone; it is even stated to have been grown in ancient Switzerland in the time of the lake dwellers. It is a small tree rarely exceeding 30 or 40 feet in height with crooked spreading branches and a dark brown rough bark. It is prone to hybridize with related species and it is probable that some of the cultivated varieties are the results of crosses with other species. The flower is white or sometimes tinged with pink, with a faint but pleasant fragrance. The fruit is a large pome which varies greatly in size, color and flavor as the result of cultivation. For medicinal purposes those varieties should be chosen which are rather firm in texture and sour in taste.

The Siberian *crab-apple, P. prunifolia* Willd., is also cultivated. Its fruit is smaller and more acid than the ordinary apple. The American or wild crab apple, *P. coronaria* L., is also cultivated to a small extent.

The expressed juice, commonly called *cider,* is a clear pale yellow liquid with a pleasant acidulous aromatic flavor. It must be obtained at the time that the cider is pressed and from reliable sources or an article preserved with sodium benzoate will be furnished by the grocer who sells large quantities of cider thus treated, for beverage purposes. It is adulterated by watering, by adding sugar or glucose, and in some cases cider has been entirely sophisticated by means of artificial flavoring and sweetening materials.

The fruit is approximately 85 per cent. of water, contains considerable amounts of sugar (7 to 8 per cent.) mostly fructose, a small amount of nitrogenous matter and a peculiar acid called *malic,* usually about a little less than 1 per cent. Pure *malic acid* (*oxysuccinic*), $C_4H_6O_5$, occurs as colorless crystals soluble in water and with a rather pleasant sour taste melting at 100° C. The characteristic flavor of the apple is chiefly due to amyl valerate.

The bark of the apple tree contains besides quercetin, the glucoside phlorizin (see Part II).

Uses.—The bark of the apple tree was at one time used as a tonic and also as an antiperiodic, but is probably of no therapeutic importance. The juice of the fruit or cider affords a pleasant acidulous drink and is slightly laxative. It is official for the purpose of preparing *ferric malate* which is the active ingredient of the ferrated extract of apples. *Iron malate* occurs in the form of brown hygroscopic scales soluble in either alcohol or water.

Off. Prep.—Extractum Ferri Pomatum, *N. F.*

SUCCUS SCOPARII. Br.

JUICE OF BROOM

Suc de Genet à Balais, *Fr.;* Besenginstersaft, *G.*

"Bruise fresh Broom Tops; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

For chemistry and therapeutic uses of this, see under *Scoparius.*

Dose, one to two fluidrachms (3.75–7.5 cc.).

SUCCUS TARAXACI. Br.

JUICE OF TARAXACUM

Suc de Pissenlit, *Fr.;* Löwenzahnwurzelsaft, Löwenzahnsaft, *G.*

"Bruise Taraxacum Root; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, two to four fluidrachms (8–15 cc.).

SUCROSUM. U. S. (Br.)

SUCROSE Sucros. [Saccharum U. S. P. IX, Sugar]

"A sugar [$C_{12}H_{22}O_{11}$] obtained from *Saccharum officinarum* Linné (Fam. *Gramineæ*) and other sources." *U. S.* "Refined Sugar is a crystallised sugar, $C_{12}H_{22}O_{11}$, obtained from the juice of the sugar-cane, sugar-beet, and other plants." *Br.*

Saccharum Purificatum, *Br.;* Refined Sugar; Cane Sugar. Saccharose; Saccharum Album; Sucre blanc officinal, *Fr, Cod.;* Sucre de Canne, Sucre de Betterave, *Fr.;* Saccharum, *P. G.;* Weisser Zucker; Zucker, Rohrzucker, *G.;* Zucchero, *It.;* Azucar refinado, *Sp.*

The *sugar cane, Saccharum officinarum,* is a perennial herb possessing a jointed, succulent rhizome, from which arises several glaucous, jointed, solid stems, from an inch to two inches in diameter, from six to twelve feet high, and containing a white and juicy pith. The color of the stem is yellow, greenish yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base. The leaves are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green color inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to Indian corn. Four varieties are mentioned: 1, the *common,* with a yellow stem; 2, the *purple,* with a purple stem and richer juice; 3, the *gigantic,* with a very large light-colored stem; and 4, the *Otaheitan,* which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and the greater length of the hairs which surround the flowers.

Sugar cane was originally indigenous in all probability to India. It has been cultivated for its saccharine juice since remotest antiquity. At the present time it is cultivated in all tropical and sub-tropical countries. It was introduced into the West Indies by the Spaniards early in the 16th century, and these islands, especially Cuba, are now the world's largest producers.

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be removed. At the end of a year or more the plant flowers, but before this takes place the canes are richest in sugar and are cut down. The quantity of sugar which they yield is variable. According to Avequin of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent.; of uncrystallizable sugar from 3½ to 4 per cent. Cane juice is said to contain 17 per cent. of crystallizable sugar, though not more than 13 per cent. is extracted in practice.

The *Sugar beet* (*Beta vulgaris* L.) is extensively grown in temperate zones as a source of sugar, or saccharose. It is extensively grown in Europe and the western United States. The plant is a biennial resembling the ordinary garden beet. The varieties yielding sugar produce rather small tuberous roots, which are either yellowish or whitish internally. They yield 10 to 18 per cent. of sucrose, depending upon selection and cultivation.

Sucrose is also largely produced in Canada and the northern parts of the United States from the sap of the sugar maple (*Acer saccharinum*). This variety is never refined or purified as it owes its value as a confection and flavor to the impurities naturally present in the crude product. Cane sugar may be obtained from cornstalks, and from the *Chinese sugar cane,* or *Sorghum saccharatum,* which latter source for a time assumed some importance in Kansas and the Northwest. In India, sugar is made from the sap of different species of palm. Crude *palm sugar* is called *jaggery.*

Preparation and Purification.—The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between a series of horizontally placed iron rollers in a mill, or they are cut in thin transverse slices and the juice extracted by diffusion with warm water. The juice, constituting 90 per cent. of the cane, though much less is actually obtained, is of a pale greenish color, sweet taste, and balsamic odor, and has a sp. gr. varying from 1.033 to 1.106. It usually contains from 15 to 20 per cent. of sucrose. As it runs out it is received in suitable vessels, and, being quickly removed, is immediately mixed with lime, in the form of milk of lime, in the proportion of about 1 part of the earth to 800 parts of the juice, and heated in a boiler to 60° C. The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at leaving the juice still slightly acid. The albuminous matter rises to the top, and forms a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by heat, the scum being carefully skimmed off as it forms. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, when it assumes a granular aspect, it is drawn off into wooden vessels with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar. The substance obtained by the evaporation of cane juice is known as *brown sugar* or *muscovado;* it is a yellowish, crystalline and somewhat moist substance, which is decolorized and purified to form granulated sugar. The syrup, by a new evaporation, furnishes an additional portion of sugar, and the liquid which finally remains, incapable of yielding more sugar with advantage, is called *molasses.* Sugar produced in this way is called "open pan" sugar. It is now almost completely displaced by "vacuum pan" sugar.

In the production of raw sugars by the vacuum pan process, the juice, after "defecation" with lime and removal of excess of lime by carbonic acid gas, is run through large filters of bone black, and then into a vacuum pan for concentration. The vacuum pan is a large evaporating pan, closed above by a dome-like top, which connects with an exhausting steam pump, so that the liquid can be concentrated under very reduced pressure. The heat is supplied by coils of steam pipes which run through the interior of the pan. The saccharine juice is evaporated in this until it begins to crystallize, and even after this fresh portions are added, so that the crystals already formed grow by accretion of fresh material. After the crystallization is complete, the warm mixture of crystals and syrup is run into "centrifugals," to which a rapid motion of revolution is given, and the crystals so drained and dried.

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture. Nearly 20 per cent. is lost in even the most efficient of the processes. Melsens, of Brussels, proposed a process, which consists in the use of calcium bisulphite. This salt is alleged to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 100° C. all coagulable matters; as a bleacher of pre-existing coloring matters, and a preventative of the formation of new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. This process is now largely used, and calcium bisulphite is used in British Guiana and other sugar-producing countries in immense quantities. Emil Pfeiffer proposed another refining process, which consists in the use of acid calcium phosphate, an agent previously recommended by Brande. Reynoso considered alumina the best defecating agent, having succeeded by means of it in throwing down almost all impurities most hurtful. He adds the acid aluminum phosphate to the cane juice, and decomposes this with lime, by which the calcium phosphate is produced and alumina separated, and all these, with some lime in excess, cause the elimination of coloring and nitrogenous matters, so that there remain in the liquid only some of the salts which normally accompany the sugar in the juice.

The refining of raw sugar forms a distinct branch of business, and the methods pursued have undergone many improvements. The sugar which contains from 88 to 90 per cent. of sucrose is first "melted"—that is, dissolved in hot water—and then sometimes clarified by heating it with bullock's blood, although sulphites, phosphates, and other defecating agents referred to in preceding processes may be used. The clarified syrup is then strained through cloth filters, whereby it is rendered limpid. The clear straw colored syrup from the bag filters is then run into the char filters—that is, large percolators filled with freshly ignited bone black. In sugar refineries these are 25 or 30 feet in height and sometimes hold several thousand pounds of bone black each and some refineries have dozens of such units. The bone black may be reactivated several times by heating and is finally discarded and sold for fertilizing purposes. A bleaching compound known as *blankit* (*sodium hydrosulphite*) is sometimes used to spare the use of bone black filters. The syrup after filtration goes to the vacuum pans. By reduced pressure the syrup is made to boil at a lower temperature, and with a diminished contact of the air, and the loss of cane sugar by change into that which was uncrystallizable is in great measure avoided. Two, three, or even four vacuum pans may be coupled together so as to economize fuel, and the vapors arising from one made to heat the next, in which a more perfect vacuum exists, allowing of evaporation at still lower temperatures. Such a combination is called a double, triple, or quadruple effect apparatus.

At one time it was the custom to discontinue the decolorization process before an entirely white sugar was obtained, and then to add a small amount of ultamarine blue to overcome the yellow appearance of the granulated sugar. This process has practically been abandoned within recent years. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar-house molasses.* Good brown sugar, in the process of refining, yields over 75 or 80 per cent. of white sugar. A comprehensive historical article by C. A. Browne, on the development of the sugar industry is found in the *A. J. P.,* 1915, p. 10.

Commercial History.—*Cane sugar* was known to the ancients. It was originally obtained from India, where it was extracted from the sugar cane. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce and costly as to be used exclusively as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently the cultivation of the cane extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the New World, to America, where it was pursued with the greatest success, and continues to be so. In America it was produced most abundantly in the West Indies, which supplies also a part of the consumption of Europe. The Cuban production has grown rapidly in recent years, and is now over 3,000,000 tons annually. About an equal quantity is produced in Germany from beets. Considerable beet-sugar is also produced in the United States.

Classification of the Carbohydrates.—The term "sugars" is applied to a large number of carbohydrates. Emil Fischer has not only made numerous syntheses in this group, but has greatly widened our knowledge of the relations of the several sugars, permitting a more comprehensive classification than formerly. While no sugars are found in nature containing less than six atoms of carbon, synthetic compounds are formed belonging in the first, or monosaccharide, class which contain three, four, and five atoms of carbon, as well as others containing seven, eight, and nine atoms of carbon. The nomenclature of the sugars is based upon the fact that simple sugar molecules are distinguished by the Greek prefixes tri, tetra, penta, etc., indicating the number of carbon atoms in the molecule; thus, glycerose, $C_3H_6O_3$, is a triose, while dextrose, $C_6H_{12}O_6$, is a hexose. These are called *monosaccharoses, monosaccharides* or *monoses*. These simple sugar molecules are taken as the basis for a secondary classification based upon the number of monoses or simple sugar molecules represented in the molecular structure of the more complex members of the group. The Greek numerical prefixes are also used to distinguish these; thus, dextrose, $C_6H_{12}O_6$, is a monosaccharide, while sucrose, $C_{12}H_{22}O_{11}$, is a disaccharide produced by the union of two monosaccharide molecules with the elimination of water. Of the simple sugars, members ranging from three to nine carbon atoms are known (trioses to nonoses), while of the broader groupings, monoses, dioses, trioses, monosaccharides, etc.), contain respectively one, two, or three of the simple sugar molecules, while polyoses or polysaccharides contain an indefinite or larger number of monoses. The classification given below is based on that of Tollens.

I. MONOSACCHARIDES.

Trioses.—Glycerose, $C_3H_6O_3$ (prepared from glycerin by oxidation).

Tetroses.—Erythrose, $C_4H_8O_4$ (prepared from erythrite by oxidation).

Pentoses.—Arabinose, $C_5H_{10}O_5$ (prepared by the action of dilute sulphuric acid upon lævorotatory gum arabic; xylose, $C_5H_{10}O_5$ (prepared by boiling beech wood and jute with dilute acids); rhamnose or isodulcite, $C_5H_9(CH_3)O_5$, methyl pentose (obtained in the decomposition of glucosides like quercitrin).

Hexoses.—Glucose or dextrose, $C_6H_{12}O_6$; fructose or levulose, $C_6H_{12}O_6$; mannose, $C_6H_{12}O_6$ (obtained by the careful oxidation of mannite); galactose, $C_6H_{12}O_6$. Floridose (obtained by the hydrolysis of certain algæ).

Heptoses.—$C_7H_{14}O_7$. Manno-heptose (obtained artificially from the corresponding mannose); gluco-heptose (obtained artificially from the corresponding glucose).

Octoses.—$C_8H_{16}O_8$. Manno-octose (prepared from the corresponding mannose); gluco-octose (prepared from the corresponding glucose).

Nonoses.—$C_9H_{18}O_9$. Manno-nonose (prepared from the corresponding mannose); glucononose (prepared from the corresponding glucose).

II. DISACCHARIDES AND TRISACCHARIDES.

Tribioses and tetrabioses are as yet unknown.

Pentabioses.—Arabinose, $C_{10}H_{18}O_9$ (has been prepared by the moderated action of dilute sulphuric acid upon arabic acid).

Hexabioses.—Cane Sugar, $C_{12}H_{22}O_{11}$; milk sugar, $C_{12}H_{22}O_{11}$; maltose, $C_{12}H_{22}O_{11}$; isomaltose, $C_{12}H_{22}O_{11}$; trehalose, $C_{12}H_{22}O_{11}$.

Hexatrioses.—Meletriose or raffinose, $C_{18}H_{32}O_{16}$; melezitose, $C_{18}H_{32}O_{16}$.

III. POLYSACCHARIDES.

(*a*) *Crystallizable polysaccharides.*—Gentianose, lactosin.

(*b*) *Uncrystallizable polysaccharides.*—Starches, lichnin, inulin, glycogen, dextrin, natural gums, pectin substances, cellulose, lignin, tunicin.

The *glucosides* are substances closely related to the carbohydrates. They are of frequent occurrence in plant tissues and are characterized by the fact that when heated with dilute acids or dilute alkalies or subjected to the action of certain enzymes, they decompose into a glucose and an alcohol, phenol, aldehyde or nitrogen compound; hence they are probably ethers or ethereal derivatives of the monoses. (See *Amygdalin, Salicin,* etc.)

Artificial glucosides have been prepared by Fischer (*B. Chem. G.,* 1893) by the interaction of a monose and an alcohol in the presence of a dehydrating agent. Glucosides contain only carbon, hydrogen and oxygen except in the case of the cyanogenetic glucosides such as amygdalin, in which the nitrogen splits off as hydrocyanic acid.

Sucrose, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1.6.

Description and Physical Properties.—"White, hard, dry crystals or blocks, or a white, crystalline powder. It is odorless, has a sweet taste, and is stable in the air. One Gm. of Sucrose is soluble in 0.5 cc. of water and in 170 cc. of alcohol, at 25° C. One Gm. is soluble in slightly more than 0.2 cc. of boiling water. It is insoluble in chloroform and in ether.

"The specific rotation $[\alpha]_D$ of Sucrose determined at 20° C. in an aqueous solution containing in each 100 cc. 26 Gm. of Sucrose, previously dried to constant weight at 105° C., and using a 200 mm. tube, is not less than $+65.9°$. An aqueous solution of Sucrose (1 in 20) is neutral to litmus paper. Ash: not more than 0.05 per cent. An aqueous solution of Sucrose (1 in 1) is colorless or at most only faintly yellow when viewed horizontally against a white background through a vertical cylinder of colorless glass having an inside diameter of about 25 mm. When kept in large, well-closed, and completely filled bottles, the solution deposits no sediment on prolonged standing (*insoluble salts, ultramarine or Prussian blue*). Its aqueous solution (1 in 10) is not affected by the addition of an equal volume of hydrogen sulphide T.S. (*heavy metals*). Ten cc. portions of the solution (1 in 10), remain clear for at least one minute after the addition of 1 cc. of silver nitrate T.S. (*chloride*) or of ammonium oxalate T.S. (*calcium*). A 5 Gm. portion of Sucrose shows no more *sulphate* than corresponds to 0.3 cc. of fiftieth-normal sulphuric acid. Dissolve 20 Gm. of Sucrose in enough distilled water to make 100 cc. and filter the solution if necessary. To 50 cc. of clear liquid contained in a 250 cc. beaker, add 50 cc. of alkaline cupric tartrate solution, heat the mixture at such a rate that approximately four minutes are required to bring it to the boiling point, and boil for exactly two minutes. Add 100 cc. of cold, recently boiled distilled water, and collect and weigh the precipitated cuprous oxide in the following manner: Prepare a Gooch crucible with an asbestos layer. Thoroughly wash the asbestos with distilled water, followed successively by 10 cc. of alcohol and 10 cc. of ether, dry at 100° C. for thirty minutes, and weigh the prepared crucible. Filter the precipitated cuprous oxide through the crucible thus prepared, thoroughly wash the residue on the filter with hot distilled water, then with 10 cc. of alcohol, and finally with 10 cc. of ether, and dry it at 100° C. The weight of the cuprous oxide does not exceed 0.155 Gm., corresponding to not more than 0.5 per cent. of invert sugar." *U. S.*

"Colorless and inodorous crystals, or in crystalline masses. Readily and completely soluble in half its weight of *water,* forming a clear, colorless and odorless syrup which does not develop an unpleasant odor when acidified with *hypophosphorous acid* and allowed to stand for twenty-four hours; the syrup, heated to about 82° C. with *solution of potassio-cupric tartrate,* does not yield more than a trace of a red or yellow precipitate (absence of glucose). Yields no *reactions* for barium, strontium, calcium, chlorides or sulphates. Ash not more than 0.05 per cent." *Br.*

Its solution, when thick and strong, is called *syrup;* when alcohol is mixed with this the sugar is gradually deposited in crystals. An aqueous solution of sugar, kept in a warm place, has the property of corroding iron, partially immersed in it, just above the line where the surface of the liquid touches the metal, and the solution itself becomes impregnated with ferrous oxide, and of a deep red-brown color. A similar effect is produced on lead, but zinc and copper are but slightly acted on. A solution of sugar possesses the property also of dissolving a large quantity of calcium hydroxide, forming a compound called *calcium saccharate.* When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique, four-sided prisms, and called *rock candy.* This is the purest form of sucrose commercially obtainable. When heated to 185° C., it melts into a viscid, colorless liquid, which on being suddenly cooled forms a transparent mass, called *barley sugar.* At a higher temperature, between 204.4° and 215.5° C., it loses two molecules of water, and is converted into a black syrupy liquid which is official in the N. F. as *Caramel.* At a still higher temperature it yields combustible gases, carbon dioxide, empyreumatic oil, and acetic acid, and there remains about one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, which is probably a colloidal suspension; such mixtures are called *oleosaccharures.* When in solution, it is not precipitated by lead subacetate, a negative property which distinguishes it from most other organic principles.

Cane sugar may be distinguished from grape sugar by the fact that it does not reduce alkaline copper tartrate (see official tests), nor basic bismuth nitrate. See the official test above.

Action of Acids and Alkalies.—The mineral acids act differently on cane sugar according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid.*) The same acid, when weak, converts it into *saccharic acid,* $(CHOH)_4(COOH)_2$, confounded by Scheele with malic acid. Concentrated sulphuric acid chars it. Diluted hydrochloric acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable invert sugar, afterwards into grape sugar, and finally into *ulmin* and *ulmic acid.* The inversion of cane sugar by dilute acids is one of the most characteristic phenomena and is utilized in its quantitative estimation and is a factor in the changes which take place in many pharmaceutical preparations. It is called inversion because the sugar before the change takes place is dextrorotatory while after the operation it is lævorotatory. The reaction is as follows:

$$\underset{\text{Sucrose}}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Dextrose}}{C_6H_{12}O_6} + \underset{\text{Levulose}}{C_6H_{12}O_6}$$

The reason for the lævorotatory power is that levulose is more strongly lævorotatory than dextrose is dextrorotatory. The amount of acid that will produce the change is very small indeed. One drop of hydrochloric acid will invert 1 lb. of sucrose in a few minutes at the optimum inversion temperature which is 80° C.

Commercial invert sugar which is used in food products and sometimes as an adulterant of honey, is usually prepared by the use of citric acid as an inversion medium, four ounces of citric acid being sufficient for 500 lbs. of sucrose. The sucrose of course must be in solution, the best density being about 1.3

A proprietary form of invert sugar is on the market under the name of *nulomoline.* Invert sugar is sweeter than sucrose and is the cause of the cloying sweetness of some syrups and preserves in which inversion has been produced by the natural acidity of the constituents.

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with lead monoxide. Boiled for a long time with aqueous solutions of potassium hydroxide, the liquid becomes brown, formic acid is produced, and two new acids are generated,—one brown or black and insoluble in water, called *melassic acid,* the other colorless and very soluble, named *glucic acid.* Alkalies and the alkaline earths are said to lessen the rotatory power of sugar in relation to polarized light, but the sugar recovers its power when the alkali is saturated. (*J. P. C.*, 4e sér., iv, 314.) The action of acids and alkalies on cane sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids naturally existing in the saccharine juice have the effect of converting the cane sugar into invert sugar, by which a loss of the sucrose is sustained. The lime, by neutralizing these acids, prevents this change. An excess of lime, however, must be carefully avoided, as it injures the product of cane sugar in both quantity and quality. The change in sugar which precedes fermentation, namely, the conversion of sucrose into the uncrystallizable invert sugar, points to the necessity of operating on the juice before that process sets in, and hence the advantage of grinding canes immediately after they are cut, and boiling the juice at once.

Molasses, sometimes Latinized in prescriptions as *Syrupus Fuscus*, is of two kinds, the West India and sugar-house. *West India molasses* is a black thick liquid, of a peculiar odor and sweet empyreumatic taste. When mixed with water and with the skimmings of the vessels used in the manufacture of sugar, it forms a liquor which, when fermented and distilled, yields *rum*. *Sugar-house molasses, golden drips*, or *grocer's syrup* is thicker than the West India molasses, and has a different flavor; as found in commerce, it is sometimes adulterated with glucose. Its sp. gr. is about 1.4 and it contains about 75 per cent. of solid matter. Both kinds of molasses contain uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and coloring matter. *New Orleans molasses* was formerly the most largely used variety, but has practically disappeared from the market, owing to the changed conditions of manufacture.

Uses.—Although sugar is so important a foodstuff to-day, it does not seem to have been widely employed in Europe until the tenth or eleventh century. It was known much earlier to the European writers, such as Dioscorides, who lived in the first century, by whom it seems to have been regarded as a sort of natural curiosity. Its food value is very high, commercial cane sugar yielding more than 4 calories of energy per gramme. It is not, however, directly utilizable by the body cells, but must first be inverted into dextrose or levulose; this is true also of the other disaccharides such as lactose and maltose. The latter, however, do not hydrolize in the same way; lactose yields both dextrose and levulose, maltose only dextrose. This inversion is accomplished in the system probably in part by the hydrochloric acid of the gastric juice, but chiefly by a specific ferment which is found throughout the whole small intestines. It occurs with great rapidity so that the body can derive energy from ingested cane sugar almost as rapidly as it can be absorbed. So rapidly, indeed, is sugar absorbed from the intestinal tract that eating large quantities of it may overwhelm the inability of the liver to withdraw the sugar from the blood and lead to hyperglycemia and the appearance of glucose in the urine; a condition which is known as alimentary glycosuria. Glucose and levulose are directly assimilable and the body can derive nourishment from them even when injected hypodermically or intravenously.

Magnus (*M. M. W.*, 1913, p. 406) claims that sugar has valuable antiseptic properties and recommends it in the treatment of various forms of *wounds*. *Schuecking's solution* consists of 0.08 per cent. of common salt, 0.033 per cent. of sodium saccharate ($C_{12}H_{21}O_{11}Na$) and in some cases also 0.003 to 0.015 per cent. calcium mono-saccharate. It is used for intravenous injection instead of physiological salt solution in *circulatory failure* and is said to directly stimulate the heart. Busacca (*Arch. di Farmacol. Sper.*, 1921, xxxi) finds that sucrose increased the amplitude of contractions of the frog's heart and has used it intravenously with asserted benefit in various forms of *heart disease*.

Sugar is much used for the purposes of preserving organic substances. It is probable that it acts by producing rapid exosmose of the fluids of the fermentative organisms, its diluted solution being in fact prone itself to undergo fermentative change. All the different kinds of sugar susceptible of the alcoholic fermentation have this power. In pharmacy, sugar is employed to render oils miscible with water, to cover the taste of medicines, to give pharmaceutical preparations consistency, to preserve them from change, and to protect certain ferruginous preparations from oxidation. Accordingly, it enters into the composition of several mixtures, pills, and powders, of syrups and confections, and of all the troches. *Molasses* is used as an excipient for pills, and on account of its hygroscopic properties it prevents hardening.

SULPHONETHYLMETHANUM. U. S. (Br.)

SULPHONETHYLMETHANE Sulphonethylmeth.

"Diethylsulphon-methylethylmethane $[(CH_3)$-$(C_2H_5)C(SO_2C_2H_5)_2]$." *U. S.* "Methylsulphonal, or diethyl-sulphone-methyl-ethyl-methane, $C_8H_{18}S_2O_4$, is an oxidation product of the mercaptol resulting from the condensation of ethyl-methyl-ketone with ethyl-mercaptan." *Br.*

Methylsulphonal, *Br.*; Methylsulphonal; Trional; Trionalum, *Fr. Cod.*; Methylsulfonalum, *P. G.*; Methylsulfonal, *G.*

The *disulphone* group of narcotics, to which belong both this and sulphonal, were introduced into medicine by Baumann and Kast in 1888. Chemically they may be regarded as methane in which two of the hydrogen atoms are replaced by ethyl-sulphone radicals ($SO_2C_2H_5$), the other two hydrogens being substituted by either ethyl or methyl groups,—in the present example one ethyl and one methyl.

Sulphonethylmethane is made by passing dry hydrochloric acid gas to saturation through a mixture of ethyl mercaptan and methyl ethyl ketone, then oxidizing the condensation product (methyl-ethyl-ketone mercaptol) by treating it with a 5 per cent. solution of potassium permanganate; the compound is purified by repeated crystallization from its solutions in boiling water.

Description and Physical Properties.—"Colorless, lustrous, odorless, crystalline scales, having a bitter taste in aqueous solution. One Gm. of Sulphonethylmethane is soluble in 200 cc. of water at 125° C. It is more soluble in boiling water; soluble in alcohol and in ether.

"A saturated aqueous solution of Sulphonethylmethane is neutral to litmus paper. It melts between 74° and 76° C. When strongly heated, it is decomposed with the evolution of sulphur dioxide. Heat about 0.1 Gm. of Sulphonethylmethane with an equal weight of powdered charcoal in a dry test tube: the characteristic, unpleasant odor of mercaptan is evolved.

"Ash: not more than 0.05 per cent. Boil 2 Gm. of Sulphonethylmethane with 100 cc. of distilled water until solution is complete: no odor develops. Cool the solution, add sufficient distilled water to restore the volume to 100 cc., filter, and to 20 cc. of the filtrate add 0.05 cc. of tenth-normal potassium permanganate: the pink color does not disappear at once (*readily oxidizable substances*). To 10 cc. of the filtrate obtained in the preceding test add a few drops of silver nitrate T.S.: no turbidity is produced at once (*chloride*). A 50 cc. portion of the same filtrate shows no more *sulphate* than corresponds to 1 cc. of fiftieth-normal sulphuric acid.

"Preserve in well-closed containers." *U. S.*

"A white crystalline powder; taste slightly bitter. Soluble in 320 parts of *water,* somewhat more soluble in dilute *alcohol.* Melting point from 76° to 76.5° C. At a red heat it decomposes with evolution of sulphur dioxide. When heated with *anhydrous sodium acetate* hydrogen sulphide is liberated. When boiled with *water* no offensive odor is developed (absence of mercaptan and mercaptol). 100 millilitres of a cold saturated aqueous solution do not immediately decolorise 1 drop of an aqueous solution (1 in 1000) of *potassium permanganate* (limit of readily oxidisable substances). No appreciable ash." *Br.*

The name methylsulphonal certainly appears to be a misnomer, as the product differs from sulphonal by the substitution of an ethyl group for one of the two methyl groups of sulphonal.

Uses.—The action of trional is very similar to sulphonal (*q.v.*) except that it is somewhat more powerful and prompt.

There appears to be no recorded case of fatal acute poisoning by trional. Sixty grains (3.9 Gm.) are said to have produced hematoporphyrinuria, but one hundred and twenty grains (7.7 Gm.) have been recovered from without very serious symptoms. Although trional is less prone than is sulphonal to cause chronic poisoning, a number of cases have occurred.

Sulphonethylmethane is used in medicine solely as a somnifacient. In doses of from fifteen to twenty grains (1.0–1.3 Gm.) it usually causes sleep in from half to an hour without unpleasant after effects. It may be administered as a powder, stirred up in half a glass of water, or enclosed in a gelatin capsule.

Dose, ten to twenty grains (0.65–1.3 Gm.).

SULPHONMETHANUM. U. S. (Br.)

SULPHONMETHANE Sulphonmeth.

"Diethylsulphon-dimethylmethane [$(CH_3)_2C(SO_2C_2H_5)_2$]." *U. S.* "Sulphonal, or dimethyl-methane-diethyl-sulphone, $C_7H_{16}S_2O_4$, may be obtained by oxidising mercaptol." *Br.*

Sulphonal, *Br.;* Diethylsulphon-dimethyl-methane; Acétoné-diéthylsulfone, *Fr.;* Sulfonalum, *P. G.;* Sulfonal, *G.* Sulfonale, *It.;* Sulfonal, *Sp.*

Preparation.—This compound belongs to the same group, to which belongs also trional. It may be made by the following processes. When anhydrous mercaptan (ethyl sulphydrate) and anhydrous acetone are mixed and a stream of dry hydrochloric acid gas passed through, the liquid gradually becomes turbid and separates into two layers, the upper being mercaptol (dithioethyldimethylmethane), the lower, diluted hydrochloric acid. The mercaptol is separated, washed, dried and purified by fractional distillation. The oxidation of the pure mercaptol to sulphonal is accomplished by potassium permanganate. It may also be prepared by the action of ethyl chloride on sodium thiosulphate, the resulting sodium ethyl thiosulphate being converted into ethyl mercaptan and acid sodium sulphate by the action of water. This conversion is made to take place in the presence of alcohol, hydrochloric acid, and acetone, the ethyl mercaptan being condensed to mercaptol, which is oxidized by potassium permanganate as in the foregoing method. A characteristic test is to fuse the sulphonal in a small dry test-tube, heat to about 280° C., and to the clear liquid add pyrogallic (or gallic) acid. The liquid becomes brown and gives off the characteristic odor of mercaptan or sulphur alcohol. Heating with potassium cyanide or even with powdered charcoal will effect the same decomposition.

Description and Physical Properties.—"Colorless, odorless crystals or a white, odorless powder. One Gm. of Sulphonmethane is soluble in 365 cc. of water, 60 cc. of alcohol, 11 cc. of chloroform, and in 64 cc. of ether, at 25° C. One Gm. is soluble in 16 cc. of boiling water and in 3 cc. of boiling alcohol. It is soluble in benzene.

"Sulphonmethane melts between 124° and 126° C. In other respects it responds to the tests for identity and purity under *Sulphonethylmethanum.*

"Preserve in well-closed containers." *U. S.*

The British Pharmacopœia gives the following description:

"Colorless, prismatic crystals. No odor; nearly tasteless. Soluble in 450 parts of cold *water,* in 15 parts of boiling *water,* and in 80 parts of *alcohol* (90 per cent.). Melting point 125° C. Aqueous solution neutral to *litmus.* When mixed with an equal weight of *potassium cyanide* and heated, the odor of mercaptan is evolved, and when to the solution of the product in *water* excess of *hydrochloric acid* and a few drops of *T. Sol. of ferric chloride* are added, a reddish color is developed. Evolves hydrogen sulphide when gradually heated with *anhydrous sodium acetate.* Yields no characteristic *reac-*

tions for chlorides or sulphates. No appreciable ash." *Br.*

Uses.—Sulphonal is used in medicine solely as a somnifacient. The sulphone hypnotics, as a group, have very little action on the system except as depressants to the higher cerebral centers. Although when given in very large dose they produce in the lower animals paresis and tremors, in quantities anywhere approaching the therapeutic dose they have almost no effect on man save to produce sleep. They are both characterized by the slowness of absorption and persistence of their action, although sulphonethylmethane is not quite so slow in its effects as sulphonmethane. Although usually not followed by disagreeable after effects, there sometimes remains some mental confusion and lassitude the following day. For some unknown reason it does not act happily in cases of heart disease and there have been reported sudden deaths in patients suffering from cardiac weakness following the use of sulphonal. It is best administered in the form of a powder stirred up in a glass of hot water or milk; it should never be exhibited in pill form.

While in single dose they are relatively safe somnifacients, when used continuously over long periods of time they give rise to serious forms of intoxication. This generally starts with constipation and vague neurasthenic pains. In the fully developed stage chronic sulphone poisoning is characterized by obstinate constipation with scaphoid abdomen, cramp-like pains in the extremities, ataxia, insomnia, and a peculiar discoloration of the urine which ranges from a faint pinkish hue to a deep port wine red. This discoloration is due to the presence of a pigment known as *hematoporphyrin*, which is probably derived from decomposition of the blood. The urine is also usually highly acid and may contain albumen and tube casts. The prognosis in chronic sulphone poisoning is always grave. In the treatment it is essential to open the bowels as promptly as possible; for this the most powerful purgatives are usually required, and their action may be assisted by high enemata. In order to hasten the elimination of the poison large quantities of water should be administered, both by mouth and by hypodermoclysis. The free use of alkalies has been recommended with the idea of correcting the acidity of the system; sodium bicarbonate may be added to physiological salt solution for hypodermic injection. Symptom treatment is rarely of any efficacy.

Because of the seriousness of the chronic poisoning by this drug—the mortality is upwards of 75 per cent.—and the insidiousness of its onset, sulphonal should never be used without interruptions for more than a week or ten days. Acute poisoning by sulphonal is rare, but Knapp has reported a case in which 450 grains produced death after unconsciousness lasting three days. Even after therapeutic doses occasionally a measles-like rash appears.

A. Falck reports that sulphonal may be recovered from decomposing animal matter after long contact (*J. S. C. I.*, 1919, xxxviii, 962A).

Dose, from ten to forty grains (0.65–2.6 Gm.).

SULPHUR LOTUM. U. S.

WASHED SULPHUR Sulphur Lot.

"Washed Sulphur, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent. of S." *U. S.*

Flores Sulphuris Loti; Sulphur Depuratum, Soufre Sublimé Lavé, Soufre Lavé, *Fr.;* Gereinigte Schwefelblumen, *G.;* Solfo sublimato e levato, *It.;* Azufre lavado, *Sp.*

"Sublimed Sulphur, 100 Gm.; Ammonia Water, 10 cc.; Water, a sufficient quantity. Pass the sublimed sulphur through a No. 30 sieve, mix it thoroughly with 100 cc. of water, add the ammonia water, and set the mixture aside for three days in a closed vessel, agitating occasionally. Then add 100 cc. of water, transfer the mixture to a strainer, and wash the sulphur with water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat in a drying closet, pass it through a No. 30 sieve." *U. S.*

Sublimed sulphur is frequently contaminated with small quantities of sulphuric acid and other impurities, and the object of the ammonia in the above process is to neutralize the acid—the salt being subsequently washed out—and to remove any arsenical contamination. (See *Sulphur Sublimatum.*)

Description and Physical Properties.—"A fine yellow powder, without odor or taste. It meets the requirements for solubility and identity under *Sulphur Sublimatum.* Agitate 2 Gm. of Washed Sulphur with 10 cc. of distilled water and filter: the filtrate is neutral to litmus paper (*acid or alkali*). The residue on ignition does not exceed 0.5 per cent. Digest 0.5 Gm. of Washed Sulphur for three hours with 10 cc. of ammonia T.S., filter the liquid, and evaporate the clear filtrate to dryness on a water bath. Add 1 cc. of nitric acid, and again evaporate to dryness. This residue meets the requirements of the test for *arsenic.*

"**Assay.**—Dry Washed Sulphur to constant weight over sulphuric acid and proceed as directed under *Sulphur Sublimatum.*

"Preserve in well-closed containers." *U. S.*

For description of chemical and therapeutic properties, see *Sulphur Sublimatum.*

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Pulvis Glycyrrhizæ Compositus, *U. S.;* Sulphuris Iodidum, *N. F.;* Tabellæ Sulphuris et Potassii Bitartratis, *N. F.*

SULPHUR PRÆCIPITATUM. U. S., Br.

PRECIPITATED SULPHUR Sulphur Præc. [Lac Sulphuris, Milk of Sulphur]

"Precipitated Sulphur, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent. of S." *U. S.* "Precipitated Sulphur is obtained by the action of hydrochloric acid upon a solution prepared by boiling together sulphur and lime in water." *Br.*

Magisterium Sulphuris; Soufre précipité, Magistère de Soufre, *Fr.;* Sulfur præcipitatum, *P. G.;* Schwefelmilch, *G.;* Solfo precipitato, *It.*

"Sublimed Sulphur, 100 Gm.; Lime, 50 Gm.; Hydrochloric Acid, Water, each a sufficient quantity. Slake the lime, and mix it thoroughly with 500 cc. of water. Add the sublimed sulphur, previously sifted, and, after thorough mixing, add 1000 cc. of water and boil the mixture in a porcelain or glass vessel during one hour, stirring or agitating the mixture very frequently, and replacing the water lost by evaporation. Then cover the vessel, and allow it to stand until the contents are cool and the supernatant liquid becomes clear. Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually and with constant stirring hydrochloric acid, previously diluted with an equal volume of water, until the liquid is nearly neutralized but still retains an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it until the washings are neutral to litmus paper and no longer give a precipitate upon the addition of ammonium oxalate T.S. Then dry the product rapidly and keep it in well-closed containers." *U. S.*

The process for *precipitated sulphur* was not changed in the last revision. The Br. Pharm. in its official definition outlines the method used in the U. S. preparation.

In the U. S. process three molecules of calcium oxide react with six atoms of sulphur to form two molecules of calcium disulphide and one of calcium thiosulphate;

$$3CaO + (S_2)_3 = 2CaS_2 + CaS_2O_3$$

On the addition of the hydrochloric acid, six atoms of sulphur are precipitated (four from the two molecules of calcium disulphide and two from the one molecule of calcium thiosulphate), and the calcium and oxygen unite with the hydrochloric acid, so as to form calcium chloride and water, according to the reaction:

$$2CaS_2 + CaS_2O_3 + 6HCl = 3CaCl_2 + 3H_2O + (S_2)_3$$

Hydrochloric acid is the most eligible precipitant for the sulphur, as it gives rise to calcium chloride, which is a very soluble salt and is easily washed away. Sulphuric acid is wholly inadmissible, as it produces calcium sulphate, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur.

Description and Physical Properties.—"A fine, amorphous powder, of a pale yellow color, without odor or taste.

"Precipitated Sulphur meets the requirements for solubility and identity under *Sulphur Sublimatum,* but it is more readily and completely soluble in carbon disulphide than the other forms of sulphur. Agitate 2 Gm. of Precipitated Sulphur with 10 cc. of distilled water, and filter: the filtrate is neutral to litmus paper (*acid or alkali*). The residue on ignition does not exceed 0.3 per cent. Digest 1 Gm. of Precipitated Sulphur for three hours with 10 cc. of ammonia T.S., and filter the liquid. Evaporate the clear filtrate to dryness on a water bath, add 1 cc. of nitric acid, and again evaporate to dryness: this residue meets the requirements of the test for *arsenic.*

"**Assay.**—Dry Precipitated Sulphur to constant weight over sulphuric acid and proceed as directed under *Sulphur Sublimatum.*" *U. S.*

"A greyish-yellow, soft powder, free from grittiness and from the odor of hydrogen sulphide. Under the microscope it is seen to consist of opaque globules, without any admixture of crystalline matter. Burns with a blue flame, forming sulphur dioxide, and leaving not more than 0.5 per cent. of fixed residue. When 10 grammes are mixed with *water,* filtered, and thoroughly washed, the mixed filtrate and washings require for neutralisation not more than 2 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). *Arsenic limit* 5 parts per million." *Br.*

The German test, that 1 Gm. of precipitated sulphur should completely dissolve in 5 Gm. of carbon disulphide, is trustworthy, according to Fittinger. From its color it was formerly called *lac sulphuris,* or *milk of sulphur.* It is insoluble in water, but dissolves in a boiling solution of potassium hydroxide, and in oil of turpentine by the aid of heat. When of a brilliant white color, the presence of calcium sulphate may be suspected, in which case the preparation will not be wholly volatilized by ignition. If pure, it communicates a harsh feel when rubbed between the fingers, owing to the friction of the particles. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in its amorphous condition, sublimed sulphur being crystalline.

Colloidal sulphur, which is said to be physiologically much more active than ordinary sulphur, may be produced by passing H_2S into a solution of SO_2 and, after decantation, adding distilled water to the precipitated sulphur, which readily dissolves, and may be freed from SO_2 by subsequent dialysis. Lunan (*Am. Drug.,* 1917, lxiv, 495) gives the following process: Hydrochloric acid (10 per cent.), 22 cc.; sodium sulphide ($Na_2S.9H_2O$), 5 grammes; sodium sulphite ($Na_2SO_3.7H_2O$), 2.6 grammes; white of two eggs; sterilized water to 1 liter. Dissolve the sodium sulphide and sulphite each separately in 250 cc. of the water, mix and add the white of egg. To this solution add the hydrochloric acid, diluted with 250 cc. of the water. The mixture is then warmed slightly, and sufficient sterile water added to make the volume 1 liter and the solution carefully dialyzed to remove crystalloids. Theoretically, the product should contain 1 in 1000 of colloidal sulphur. The chemical action is explained as follows:

$$2Na_2S + 4HCl = 2H_2S + 4NaCl$$
$$Na_2SO_3 + 2H_2S + 2HCl = 2NaCl + 3S + 3H_2O$$

The presence of the albumin appears to prevent the aggregation of the sulphur into masses. In use the dose of 1 cc. (about 17 minims) is rendered isotonic by the addition of 0.2 cc. (about 3 minims) of 5.5 per cent. saline solution mixed immediately before injecting. *Sulfidal* and *sulfoform* are trade names for preparations of colloidal sulphur.

Uses.—Precipitated sulphur possesses medicinal properties similar to those of sublimed sulphur. Its state of extreme division renders it more readily suspended in liquids. A form easily suspended in water may be prepared by adding to the calcium polysulphide solution a solution of casein. The precipitated sulphur carries with it a little casein which communicates through its colloidal effect suspending properties to the sulphur. It is sometimes selected for forming sulphur ointments; these are lighter in color and smoother than those made with sublimed sulphur.

Dose, one to three drachms (3.9–11.6 Gm.).

SULPHUR SUBLIMATUM. U. S., Br.

SUBLIMED SULPHUR Sulphur Sublim.
[Flowers of Sulphur]

"Sublimed Sulphur, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent. of S." *U. S.* "Sublimed Sulphur may be obtained from native sulphur or sulphides." *Br.*

Flores Sulphuris; Brimstone; Soufre Sublimé, Fleur (Crême) de Soufre, *Fr.;* Sulfur sublimatum, *P. G.;* Schwefel, Schwefelblumen, Schwefelblüthe, *G.;* Solfo sublimato, *It.;* Azufre sublimado, Flor de Azufre, *Sp.*

Natural States.—Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is present in volatile oil of mustard and other cruciferous plants. It occurs in the earth either free or in combination. When free it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphides. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur.* Productive mines of sulphur are found in Sicily, but the output has declined in recent years. Sulphur exists as a mineral in widely separated localities in the United States. Two hundred miles south of Salt Lake City there is a deposit of sulphur two thousand feet square and of an unknown thickness, shafts having been sunk sixty feet without reaching the bottom. This sulphur is said to be free from arsenic and antimony and is a surface deposit. Much sulphur has been found in Mount Humboldt, Nevada, and Sulphur Mountain, as it is called, in the Yellowstone National Park, is largely composed of the mineral. The great bulk of the world's supply of sulphur is now produced from the mines in Louisiana and Texas which now yield (1922) approximately 1,000,000 tons annually. In the Frasch process, used in these mines, a well 25 cm. in diameter is sunk just as in boring for petroleum. This is lined with an iron pipe all the way to the rock formation underlying the sulphur deposit. In this tube are placed two aluminum lined concentric tubes which are driven to the lower portion of the sulphur layer but not entirely to the rock. The outer tube is then surrounded with water heated under pressure to 155° C., which melts the sulphur and forces it to ascend the middle tube as a liquid with a density of 2. A current of compressed air meets the sulphur and fills it with air bubbles which render it buoyant and it rises to the surface without the aid of a pump. The Louisiana sulphur is nearly 100 per cent. pure and is entirely free from arsenic, which is very advantageous for many industrial processes and for making pure sulphuric acid (see *Acidum Sulphuricum*). Sulphur exists in large quantities also in various localities in Japan.

Sicilian sulphur is usually extracted from the sulphur-containing earth by heating in covered mounds known as *calcaroni,* and collecting the melted sulphur or by extraction from the earth by superheated steam under several atmospheres' pressure.

The process of purifying the crude Sicilian sulphur consists in distilling the crude sulphur from a large cast iron still, set in brickwork over a furnace and furnished with an iron head. The head has two lateral communications, one with a chamber of brick-work, the other with an iron receiver immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and the receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur,* or *flowers of sulphur.* If, on the other hand, the communication with the chamber be closed, and that with the receiver open, the sulphur will condense in the latter in the fused state and, when cast in cylindrical moulds, forms the *roll sulphur* of commerce.

In the island of Anglesea, and at Swansea, Wales, large quantities of sulphur are obtained from imported Spanish copper pyrites in the process for extracting the metal. The furnaces in which the ore is roasted are connected with chambers in which the volatilized sulphur is condensed.

A process for obtaining sulphur as a by-product from the residue of the manufacture of soda by the LeBlanc process, proposed by Max Schaffner, has been used in most of the soda factories of Germany, and has been introduced, to a greater or less extent, in England, France, and Belgium.

Crude foreign sulphur has come to this country principally from Messina, in Sicily, and the ports of Italy, but in recent years Japanese sulphur has been received on the Pacific coast. Roll sulphur and the flowers were formerly brought from Marseilles. Good Sicilian sulphur does not contain more than 3 per cent. of impurity, consisting chiefly of earths. The Louisiana sulphur has practically replaced much of the foreign sulphur.

Sulphur is a non-metallic element, existing in several allotropic states. In its ordinary state it is a brittle solid, of a pale yellow color, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible odor when rubbed. When pure its sp. gr. is about 2, but it varies a little in density in its different allotropic states. It is a poor conductor of heat, and becomes negatively electric by friction. The melting point of sulphur varies with its allotropic state, which is readily altered by heat. Pure sulphur melts and sublimes at 114.5° C. If heated above its melting point, it undergoes, in proportion to the heat applied, a progressive change, which will cause it, upon slow cooling, to solidify at a temperature lower than that at which it was melted; and if it be remelted it will be found to have a higher melting point than before. Melted sulphur is perfectly limpid, and of a bright yellow color. When sulphur is melted, and, after partial cooling, the crust formed on its surface is pierced, and the fluid portion poured out, it may be obtained in slender monoclinic crystals, constituting an allotropic condition of the element. This variety, however, gradually passes back into the more permanent variety found in nature. When sulphur is heated above its melting point, it becomes deeper in color and less fluid. At 200° C. it has a deep brown color, and is so viscid that it cannot be poured from the containing vessel. If the temperature be still further increased, the sulphur resumes its fluidity, but retains its brown color. Finally, when the temperature reaches 448.4° C., it boils, forming a yellow vapor, and may be distilled. If melted sulphur, heated above 200° C., is suddenly cooled by being poured out into water, it becomes a reddish-brown plastic mass, with alteration of properties, called *soft sulphur* (*viscid sulphur*), which constitutes another allotropic variety, and is employed in taking impressions of medals, etc. This form of sulphur resumes the hard state, but not its original color, after the lapse of a few days, or suddenly if heated to 100° C.

Sulphur takes fire at about the temperature of 148.8° C., and burns with a blue flame, combining with the oxygen of the air, and giving rise to sulphurous oxide, SO_2. The combinations of sulphur are numerous, and are among the most powerful chemical agents. It forms with oxygen four oxides, *sulphurous oxide* (*sulphur dioxide*), SO_2, *sulphuric oxide* (*sulphur trioxide*), SO_3, *sulphur sesquioxide,* S_2O_3, and *sulphur heptoxide,* S_2O_7. The first two of these oxides, by their union with water, form *sulphurous acid,* H_2SO_3, and *sulphuric acid,* H_2SO_4, respectively. There are also known *hyposulphurous acid,* H_2SO_2, the corresponding oxide of which is not known, *thiosulphuric acid* (frequently spoken of as hyposulphurous acid), $H_2S_2O_3$, *persulphuric acid,* $H_2S_2O_8$, and a series of acids, $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$, and $H_2S_5O_6$, called the *thionic series.* It forms with hydrogen, hydrogen sulphide (hydrosulphuric acid or sulphuretted hydrogen), and with the metals, various *sulphides.* Some of the sulphides are analogous to oxyacids, others to basic hydroxides; and these different sulphides, by combining with one another, form compounds which, from their analogy to salts, are called Berzelius *sulphosalts.*

Description and Physical Properties.—"A fine, yellow powder having a faint odor and taste. Sublimed Sulphur is practically insoluble in water, and nearly insoluble in alcohol. One Gm. dissolves slowly and usually incompletely in about 2 cc. of carbon disulphide. One Gm. is soluble in about 70 cc. of chloroform, in 150 cc. of ether, and in 100 cc. of olive oil.

"At about 115° C. Sublimed Sulphur fuses to a yellow, mobile fluid, which upon further heating to about 162° C. becomes dark and viscid. In the air it burns to sulphur dioxide, which can be recognized by its characteristic odor. The residue in ignition does not exceed 0.5 per cent.

"**Assay.**—Dry about 1 Gm. of Sublimed Sulphur to constant weight over sulphuric acid, weigh accurately, and transfer to a flask containing 50 cc. of a solution of potassium hydroxide (1 in 10). Boil the mixture until the liquid is of a transparent, golden-yellow color and then dilute it with distilled water to measure exactly 250 cc. Oxidize 25 cc. of this diluted solution by the addition of solution of hydrogen dioxide in excess (using about 50 cc.), heat on a water bath for thirty minutes, acidulate the liquid with hydrochloric acid, dilute it with 250 cc. of distilled water, heat to boiling and add hot barium chloride T.S., in small portions, to the resulting liquid until no further precipitation takes place. Heat this mixture on a water bath for thirty minutes, collect the resulting precipitate on a filter, wash, dry, ignite, and weigh the barium sulphate. Carry out a blank determination, using the same amount of all of the reagents but omitting the Sulphur, and before making the final calculation deduct the amount of barium sulphate thus obtained from that obtained in the assay. The weight of the barium sulphate thus obtained, multiplied by

0.1373 indicates its equivalent of sulphur. Each Gm. of Sublimed Sulphur, previously dried, corresponds to not less than 7.243 Gm. of $BaSO_4$." *U. S.*

"A slightly gritty powder of a bright greenish-yellow color. Odorless and tasteless. Under the microscope it is seen to consist of irregular angular particles mixed with almost opaque globules. Burns with a blue flame, forming sulphur dioxide, and leaving not more than 0.25 per cent. of fixed residue. When 10 grammes are mixed with *water,* filtered, and thoroughly washed, the mixed filtrate and washings require for neutralisation not more than 5 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). *Arsenic limit* 5 parts per million." *Br.*

It is always contaminated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. Accordingly, it always reddens litmus, and, if the acid is present in considerable quantity, sometimes cakes. It may be freed from acidity by careful washing with diluted ammonia water. (See *Sulphur Lotum.*)

Noyer (*Caoutchouc and Gutta Percha,* 1918, xv, 9661) states that in the commercial production of sublimed sulphur the deposit on the floor of the condensing chamber consists of a number of well defined layers possessing somewhat differing physical properties. He describes four distinct varieties and states that the term *"flowers of sulphur"* should be restricted to samples containing a minimum of 33 per cent. of sulphur insoluble in carbon disulphide. All other varieties should be called simply *"Sublimed Sulphur."*

Uses.—Elemental sulphur is free from local effect and is so insoluble that it cannot be absorbed, and hence exercises no effect upon the system. When taken into the alimentary canal, however, a portion of it unites to form hydrogen sulphide, which is an active agent. By virtue of its local irritant action upon the mucous membrane the latter substance provokes intestinal peristalsis and therefore sulphur exercises a laxative influence. The movements produced by it are soft, generally without griping, and it is a frequently used laxative in cases of *hemorrhoids.* A certain amount of the hydrogen sulphide formed may be absorbed; indeed it is asserted that the sweat of persons taking sulphur will cause a black deposit of sulphide upon silver coins. Although the therapeutic properties of hydrogen sulphide have not been clearly determined, sulphur has been widely used as an alterative, especially in *chronic rheumatism* and *gout.* Besides this, a portion of the sulphide will be eliminated through the mucous membrane of the respiratory tract and sulphur may therefore exercise a beneficial action in *chronic bronchitis* and *asthma.*

The most important uses, however, of sulphur are external. When brought in contact with the skin, especially in the presence of alkalies, a similar union of sulphur with hydrogen takes place as in the intestines. The alkaline sulphide thus formed is an active poison to various pathogenic parasites and sulphur is therefore a useful remedy in such diseases as *scabies, ringworm,* and *favus.* Besides this effect the sulphides by their local stimulating effect tend to overcome congestion in the skin and they have the power of softening the horny elements. For one or the other of these effects sulphur is a valuable remedy in a number of non-parasitic diseases of the skin, especially *acne, psoriasis, seborrhea,* etc. Locally it may be employed either in the form of a suspension or in an ointment in strengths of from 5 to 20 per cent. It is often incorporated in soaps. For local application the precipitated sulphur is the best because of its finely divided state. For internal administration either the washed or precipitated sulphur may be employed.

Soluble *colloidal sulphur* is asserted by Joseph (*Derm. Cb.,* 1913) and others to be superior to the official sulphur in the treatment of skin diseases. It is used in strengths of from 2 to 20 per cent. It has also been recommended by Bourges (*J. P. C.,* 1918, xvii, 243) internally in the treatment of *rheumatism.* It appears to be more toxic than the ordinary sulphur. (See Duhamel, *J. P. C.,* 1919, xx, 78). See under *Sulphur Precipitatum* for method of preparation.

According to Hannon of Brussels, *soft sulphur,* recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The *dose* of soft sulphur is from twenty to fifty grains (1.3–3.2 Gm.), given in the form of pill. It has also been successfully employed for filling the hollows of *carious teeth.* (*P. J.,* xvii, 330.) Sublimed sulphur has been used with extraordinary success in South Africa and the Philippines in the treatment of *ameboid dysentery.* It acts probably by killing the ameba. It may be given in divided doses up to two hundred grains (13 Gm.) a day.

Much sulphur is consumed in the arts, principally in the manufacture of gunpowder and of sulphuric acid.

Dose, one to three drachms (3.9–11.6 Gm.).

SUMBUL. N. F.

SUMBUL [Musk-root]

"Sumbul consists of the dried rhizome and roots of *Ferula Sumbul* (Kaufmann), Hooker filius, or of other closely related species of

Ferula (Fam. *Umbelliferæ*) possessing a characteristic musk-like odor. Sumbul contains not more than 2 per cent. of foreign organic matter." *N. F.*

Sumbul Radix; Racine de Sumbul, *Fr.;* Sumbulwurzel, Moschuswurzel, *G.*

Under the name of *sumbul* or *jatamansi,* a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It was the root of a then unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Bootan, Pucharia, etc. The root is taken northward to Russia, and reaches the rest of Europe through Petrograd. The physicians of Moscow and Petrograd were the first to employ it on the continent of Europe. Granville first introduced it to the notice of the profession in Great Britain and in this country. It has also been imported into England from India, whither it was brought from a great distance. The species which yields the drug of commerce has not been definitely ascertained. The U. S. P. IX recognized *Ferula Sumbul* Hooker fil. as the source but this is denied by Holmes, although this author states it was probably the source of the original drug.

Ferula Sumbul was first discovered by the Russian Fedschenko in 1869, growing at an elevation of 3000 feet in the mountains which separate Russian Turkestan from Bucharia. The plant is a large umbellifer, reaching a height of eight feet, and having a solid, cylindrical, slender stem, which in the upper part gives origin to about twelve slender divaricate branches. The root-leaves are two and a half feet long, with short, channelled, broadly dilated, completely clasping petioles. They are triangular in outline, tripinnate, with the alternate divisions fine. The stem-leaves rapidly decrease in size until they become mere sheathing bracts. The flowers are polygamous, the fruit from three-eighths to one-half inch long by one-fourth inch wide; the mericarps oblong-oval, dorsally much compressed, thin, with three faint, thread-like, dorsal ridges; no dorsal vittæ, and commissural ones collapsed. J. E. Aitchison states (*Tr. Linn. Soc.,* ser. 2, *Bot.,* 69) that the root of *Ferula suaveolens,* which has only a faint musky odor, is one of the kinds exported from Persia to Bombay by the Persian Gulf.

The commercial supplies of Sumbul are imported from Turkey.

Description and Physical Properties.—"*Unground Sumbul.*—In transverse segments, attaining a length of 10 cm. and a diameter of 7 cm.; extremely light, floating in water; externally light brown to dark brown, longitudinally wrinkled and showing in the upper portions a smooth, grayish or brownish epidermal layer, occasionally with the short stem-bases attached; fracture short, fibrous, spongy; internally light yellow or brownish yellow, arrangement of wood irregular and with yellowish brown or blackish resinous patches frequently extending over the entire ends of the segments. Odor peculiar, musk-like; taste bitter and somewhat aromatic.

"*Powdered Sumbul.*—Grayish brown; exhibits numerous, irregular, brownish black fragments and well-defined isolated tracheæ, the latter with distinct end-walls, and mostly with reticulate thickenings and from 0.020 to 0.100 mm. in width; occasional fragments of polygonal epidermal cells with yellowish brown walls; numerous, nearly colorless, yellowish brown and reddish brown fragments consisting of a granular substance in which the cellular structure is not well defined; long, narrow fragments consisting of more or less collapsed sieve tissue; occasional fragments of well-defined parenchyma with a few, nearly spherical starch grains, from 0.003 to 0.012 mm. in diameter." *N. F.*

Constituents.—An elaborate analysis of sumbul by Heyl and Hart (*A. J. P.,* 1916, p. 546) showed in addition to the ordinary constituents of vegetable drugs, about 17 per cent. of resinous matter and 1 per cent. of volatile oil. The resinous matter consisted of a considerable proportion of a white acid resin which yielded upon hydrolysis vanillic acid and a substance resembling the volatile oil described below. From this resinous matter was also separated phytosterol, an unsaponifiable substance, $C_8H_{13}O$ and by saponification several fatty acids including *angelic* (*sumbulic*), valerianic, butyric, etc. The volatile oil had a specific gravity of 0.932 at 15° C., and on standing deposited a few yellow crystals of undetermined composition; it contained no sulphur. They also found traces of umbelliferone, both free and as a glucoside, and betaine.

For other analyses but less complete see Utech (*A. J. P.,* 1893, p. 465) and Hahn (*Proc. Penna. Phar. Assn.,* 1896, p. 75).

Uses.—Sumbul is supposed to have a quieting influence on the nervous system and is used in the treatment of various *hysterical* conditions. By many it is believed to have an especial relation to the pelvic organs and it is widely employed in *dysmenorrhea* and allied disorders. It has also been used as a stimulant to mucous membranes not only in *chronic dysenteries* and *diarrheas,* but in *chronic bronchitis,* especially with *asthmatic* tendency, and even in *pneumonia.*

Murawieff, of Russia, prepares the resin, which he considers to be the active principle, by macerating the root first in water, and then in a solution of sodium carbonate, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it.

Dose, from fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Extractum Sumbul, *N. F.;* Tinctura Sumbul, *N. F.*

SUPPOSITORIA. U. S.

SUPPOSITORIES

"Suppositories are solid bodies of various weights and shapes, adapted for introduction into the different orifices of the human body, and melting or softening at body heat. The vehicles usually employed are oil of theobroma, glycerinated gelatin, or sodium stearate." *U. S.*

Suppositoires, *Fr. Cod.;* Suppositorien, Stuhlzäpfchen, *G.;* Supositorios, *Sp.*

Suppositories are solid bodies usually intended to be introduced into the rectum with a view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighboring parts or on the system at large. Suppositories are also made for vaginal or urethral administration. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical, the last being preferable when the bulk is small, or they may be in the shape of the modified cone with a tapering base, as recommended by H. S. Wellcome. (*Proc. A. Ph. A.,* 1893, p. 103.) This is the form now generally used when moulded suppositories are supplied. They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. Soap is not unfrequently employed in this way as a laxative, a piece of pure castile soap being cut to the proper shape and used as a suppository. Cacao Butter, originally recommended by A. B. Taylor (*A. J. P.,* 1852) is the most frequently used base (see *Oleum Theobromæ*). Rarely is it necessary to stiffen it but when such a material is employed, wax is usually selected, although cetaceum is preferable. If not more than 10 per cent. of the spermaceti is added, the value of the suppository is not very materially affected, although it melts more slowly, and consequently requires a longer time to act, than when the butter of cacao is used alone. Suppositories containing a considerable percentage of wax melt so slowly in the rectum as to be comparatively useless, or they may fail altogether to soften down, and be finally passed from the anus unchanged.

A critical study and contribution to the literature of suppository bases was published by Bruno Solomon (*Ph. Ztg.,* 1913, p. 502), who classifies them in general as (1) cacao butter, (2) fat and wax combinations, (3) glycerin and gelatin, agar, soap, etc. He prepares what he calls a *mother mass* of gelatin 50, distilled water 100, and glycerin 100. From this, modifications with agar-agar and soap, etc., may be subsequently prepared with the minimum of effort. The U. S. P. gives a formula for preparing suppositories with a glycerin gelatin base.

A very good method of mixing the oil of theobroma with the hardening material is by grating with an ordinary tin grater, such as used in kitchens, and mixing the coarse powders before melting, and W. G. Ewing has proposed rubbing the powders and the medicinal substance in a mortar together, dividing the plastic mass, and shaping it with the fingers. It is better to shape them with a spatula, and roll them upon a pill tile. This plan, although having its advantages, is, however, not equal to the official one of melting the ingredients and running them into moulds. The tendency of the hardened suppositories to adhere to the moulds may be overcome more or less perfectly by dusting the moulds with lycopodium powder, or greasing them well with olive oil, but it is far better to rely upon the natural contraction of the mass, caused by thoroughly cooling the moulds as lycopodium is a foreign substance which sometimes produces irritating effects, and oil sometimes makes them too soft, when used too freely. The moulds that open lengthwise, are now used almost exclusively in preference to the archaic individual moulds. The mould must be very cold, so as to chill the melted liquid at once and prevent any separation of its ingredients before cooling. It has also been recommended to form the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards enclosed by a little of the cacao butter. But, as one of the objects of the excipient is an equable diffusion of the medicine, to prevent irritation, this method would be inapplicable to substances in any degree locally irritant. Hollow rectal suppositories made of pure cacao butter are on the market and have an extensive use; the medicinal ingredients are made into a soft mass rolled out on a slab or cut into pieces on a pill machine, inserted into the hollow chamber of the suppository and the cacao butter plug there fused in place with the use of gentle heat.

J. Percy Remington devised a suppository mould made of soft vulcanized rubber; it is used in the same manner as that employed for a metal mould, the advantage being mainly the facility of removal when the suppository is cold; a slight pressure with a twisting motion causes the soft rubber mould to open, and the suppository to drop out easily. (*Proc. New Jersey Pharm. Association,* 1906.)

The inventive genius of pharmacists has been industriously applied to the construction of suppository moulds, and there are now many varieties; the principle is much the same in all, however, but for convenience they may be classed as follows: 1. Individual moulds; these were among the first to be used. Half a dozen conical, hard-metal moulds, or made of paper, tin-foil, etc., are retained in an upright position in a tray containing ice-water. (See *A. J. P.*, 1861, p. 5, 1870, 392; *Proc. A. Ph. A.*, 1902, 501.) 2. Moulds which consist of two solid pieces of metal, hinged or temporarily joined, so that when the suppository is thoroughly cooled the parts may be separated and the suppository dropped out. (See *A. J. P.*, 1871, pp. 488, 563; 1879, p. 277; and *Proc. A. Ph. A.*, 1893, p. 103; 1902, 757.) 3. Soft rubber moulds. (See *Proc. New Jersey Pharm. Assoc.*, 1906.) 4. Moulds designed to be used through compression, more or less powerful. (*N. R.*, June, 1879, Jan. and March, 1880; also *Proc. A. Ph. A.*, 1897, p. 442.)

The weight—*i.e.*, the size—of rectal suppositories should vary according to the purposes for which they are employed. When they are to be used for infants and children, they should weigh from five to ten grains. The Br. Pharm. adopts the weight of 1 Gm. (fifteen grains).

Machines for making suppositories by cold compression are now available in a variety of forms, and, while they are more satisfactory for making stock suppositories, made up in large numbers, many retail pharmacists use them to advantage in dispensing suppositories on prescription. (For a discussion of such machines and their relative advantages see Remington, *Practice of Pharmacy.*) Compression is now recognized as an alternative method in the U. S. P. general article on suppositories.

The U. S. P. X directs as follows:

"For suppositories made with oil of theobroma the following general processes may be employed: Take of the Medicinal Substance, the prescribed quantity; Oil of Theobroma, grated, a sufficient quantity. Reduce the medicinal substance, if dry, to a very fine powder, or, if an extract, soften it with an appropriate liquid, then mix it thoroughly in a mortar with about an equal weight of grated oil of theobroma, and incorporate the remainder of the oil of theobroma until a homogeneous, plastic mass is obtained, adding, if necessary, a small quantity of expressed oil of almond or wool fat. Roll the mass on a graduated tile until a cylinder of the proper length is formed, divide this into the required number of equal parts, and with a spatula, or other mechanical aid, form them into the desired shape.

"If the process of cold compression is preferred, mix the medicinal substance in a suitable mortar with about an equal weight of grated oil of theobroma, as above directed, then thoroughly incorporate it with the remainder of the oil of theobroma, previously finely grated, chilling the mortar, if necessary, to preserve the pulverulent form of the mixture. Transfer the powdered mass to the cylinder of an appropriate suppository compressor and by the use of this apparatus prepare the desired number of compressed suppositories. If the process of fusion is preferred, mix the medicinal substance with about an equal weight of grated oil of theobroma, as above directed, then thoroughly incorporate it with the remainder of the oil of theobroma, previously melted by a gentle heat on a water bath, in a suitable vessel provided with a lip. Allow it to cool to about 38° C., and, when the mixture begins to congeal, pour it immediately into suitable well-cooled moulds. Keep the moulds at a freezing temperature until the suppositories have hardened and are ready to be removed. For suppositories containing chloral hydrate, phenol, or other substances which soften the vehicle, raise the melting point of the oil of theobroma by the addition of from 10 to 15 per cent. of spermaceti, but the melting point must not be raised above 37° C.

"For suppositories made with glycerinated gelatin the following process may be used: Take of: The Medicinal Substance, the prescribed quantity, Glycerinated Gelatin, Glycerin, Water, each, a sufficient quantity. Mix the medicinal substance, if solid and soluble in water or glycerin, or if a miscible liquid, with a little water, and add sufficient glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it at once into suitable moulds which have been greased with a small quantity of petrolatum. Cool the moulds thoroughly before removing the suppositories. Moulds for urethral suppositories should be warmed sufficiently before pouring the mass to facilitate the proper filling of the mould. Suppositories having a firmer consistence may be prepared by substituting mucilage of acacia for a portion of the water or glycerin. If the medicinal substance is insoluble in water or glycerin, thoroughly triturate it in a warm mortar with a sufficient quantity of glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it into suitable moulds as above directed. With bulky powders about one-half of the glycerin may be replaced with water before trituration. Glycerinated gelatin suppositories should be protected against the effects of heat, moisture, and dry air by keeping them in tightly-closed containers in a cool place.

"*Rectal Suppositories* should be cone-shaped, and when made from oil of theobroma should weigh about 2 Gm. If prepared with glycerinated gelatin, they should weigh about 4 Gm. *Urethral Suppositories* (*Bougies*) should be pencil-shaped, pointed at one extremity, and either 7 cm. in length, weighing about 2 Gm., or 14 cm. in length, weighing about 4 Gm., when made with glycerinated gelatin. If prepared with oil of theobroma they should weigh about one-half the above quantities. *Vaginal Suppositories* should be globular or oviform in shape, and weigh about 10 Gm. if made with glycerinated gelatin, and about 4 Gm. if made with oil of theobroma." *U. S.*

The U. S. Pharmacopœia gives no detailed formulæ for suppositories, except in one case, *Suppositoria Glycerini.*

Suppositories are used in medicine (1) for the purpose of obtaining the systemic action of drugs after their absorption, (2) for the local effects of their ingredients. There is an old superstition among the medical profession that systemically acting drugs introduced per rectum have more effect upon the pelvic organs than when given by the mouth, and suppositories of opium, belladonna, etc., are habitually recommended in the treatment of diseases of the bladder and uterus. This view, however, is patently erroneous. The per rectum channel of exhibiting systemically acting drugs may, however, be of service in those cases in which deleterious influence upon the stomach is feared. Speaking in a general way, quantities of about double the dose exhibited by the mouth may be given in the form of suppositories. As a means of obtaining the local action of astringents, anesthetics, or antiseptics, upon the mucous membrane of the rectum suppositories are very valuable.

SUPPOSITORIA ACIDI CARBOLICI. Br.

PHENOL SUPPOSITORIES

Carbolic Acid Suppositories; Suppositoires d'acide Phénique, *Fr.;* Phenol-suppositorien, *G.*

"Phenol, 0.8 gramme; White Beeswax, 0.5 gramme; Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Dissolve the Phenol in the Oil of Theobroma, previously melted, add the White Beeswax, and pour the melted mixture into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains 0.067 gramme (about 1 grain) of Phenol." *Br.*

These suppositories may be used to obtain the local anesthetic and antiseptic effect of phenol. The wax is needed to offset the tendency to liquefy.

SUPPOSITORIA ACIDI TANNICI. Br.

TANNIC ACID SUPPOSITORIES

Suppositoires de Tannin, *Fr.;* Tanninsuppositorien, Tannin-Stuhlzäpfchen, *G.*

"Tannic Acid, 2.4 *grammes;* Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Melt the Oil of Theobroma; triturate the Tannic Acid intimately with a little of the Oil, and add to the remainder; stir well; as the mixture begins to thicken pour it into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Tannic Acid." *Br.*

This remedy is especially applicable to cases of *piles* and *prolapsus of the rectum.*

SUPPOSITORIA BELLADONNÆ. Br.

BELLADONNA SUPPOSITORIES

Suppositoires de belladone, *Fr.;* Belladonnasuppositorien, *G.*

"Liquid Extract of Belladonna, 1.7 *millilitres;* oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Evaporate the Liquid Extract of Belladonna to a syrupy consistence; mix with the Oil of Theobroma, previously melted; as the mixture begins to thicken pour it into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains, approximately, 0.001 gramme (about 1/60 grain) of the alkaloids of Belladonna Root." *Br.*

SUPPOSITORIA GLYCERINI. U. S., Br.

SUPPOSITORIES OF GLYCERIN Supp. Glycerin.

Suppositoires de Glycérin, *Fr.;* Glycerinsuppositorien, *G.*

"Glycerin, 80 Gm.; Monohydrated Sodium Carbonate, 2 Gm.; Stearic Acid, 8 Gm.; Water, 10 cc.; to make about 30 suppositories. Dissolve the monohydrated sodium carbonate in the water and add it to the glycerin contained in a suitable vessel, placed in a water bath in such a way that the vessel is well immersed in the boiling water and its contents protected as much as possible from the steam of the bath. Add the stearic acid and heat the mixture for fifteen minutes or until the carbon dioxide ceases to be evolved, and the liquid is clear. Then pour the melted mass into suitable moulds, remove the suppositories when they are completely cold, and preserve them in tightly-stoppered glass vessels in a cool place." *U. S.*

"Gelatin, cut small, 14 *grammes;* Glycerin, 70 *grammes;* Distilled Water, *a sufficient quantity.* Soak the Gelatin in the Distilled Water for five minutes, or until thoroughly softened; drain well, add the Glycerin, dissolve on a water-bath and evaporate until the mixture weighs one hundred grammes. Pour the product into suitable moulds having capacities corresponding to two, four, or eight grammes of the Suppository, or of such other capacities as may be required. Each of these Suppositories contains 70 per cent. by weight of Glycerin." *Br.*

These were official for the first time in the U. S. P. 1890. Glycerin suppositories have come into extensive use, the object being to introduce glycerin into the rectum with a minimum amount of other ingredients. Stearic acid was selected on account of its forming with sodium carbonate the hardest soap attainable, thus permitting the introduction of a suppository containing at least 90 per cent. of glycerin, the water, added to dissolve the monohydrated sodium carbonate, and some of the glycerin being evaporated during the manipulation. This process was perfected by J. P. Remington. (See *Practice of Pharmacy.*) The British method, on account of the use of gelatin, permits the presence of only 70 per cent. of glycerin, the suppository not being firm enough for convenient application, and, in addition, the method of hydrating the gelatin is faulty. (*C. D.*, 1898, 831.) Instead of wrapping the suppositories in tin foil it will be found more satisfactory to insert each one in a small glass tube of the proper size, corked at both ends, or in small individual cylindrical vials. Some protection from the moisture in the air is necessary because of the hygroscopic character of glycerin. (See *P. J.*, 1895, 182; *Am. Drug.*, 1894, 91; *A. J. P.*, 1895, 599.)

Uses.—Glycerin suppositories are very much used to produce fecal discharges in *constipation.* They act by locally irritating the mucous membrane of the rectum, and are often satisfactory, though never really purgative. As an occasional remedy they are useful, but their habitual employment is probably injurious to the mucous membrane.

SUPPOSITORIA IODOFORMI. Br.

IODOFORM SUPPOSITORIES

Suppositoires d'Iodoforme, *Fr.;* Iodoformsuppositorien, *G.*

"Iodoform, in powder, 2.4 *grammes;* Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Iodoform." *Br.*

These suppositories are valuable in cases of rectal inflammation and irritation. It is often possible by their use in *dysentery* to avoid the use of opium to a greater or less extent. They are especially serviceable to relieve the pain and itching of *hemorrhoids.*

SUPPOSITORIA MORPHINÆ. Br.

MORPHINE SUPPOSITORIES

Suppositoires de Morphine, Suppositoires morphinés, *Fr.;* Morphinumsuppositorien, Morphin-Stuhlzäpfchen, *G.*

"Morphine Hydrochloride, 0.2 *gramme;* Oil of Theobroma, *a sufficient quantity,* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.017 gramme (about ¼ grain) of Morphine Hydrochloride." *Br.*

These may be used to obtain the systemic effects of morphine when, for any reason, it is undesirable to exhibit that drug by mouth.

SUPPOSITORIA PLUMBI COMPOSITA. Br.

COMPOUND LEAD SUPPOSITORIES

Suppositoires de Plomb composés, Suppositoires de Plomb opiacés, *Fr.;* Zusammengesetzte Bleisuppositorien, *G.;* Stuhlzäpfchen von Opium und Bleizucker, *G.*

"Lead Acetate, in powder, 2.4 *grammes;* Opium, in powder, 0.8 *gramme;* Oil of Theobroma, *a sufficient quantity,* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Lead Acetate, and 0.067 gramme (about 1 grain) of Opium." *Br.*

This irrational combination is occasionally used in *diarrhea* or *hemorrhoids.*

SYRUPI

SYRUPS

Sirops, *Fr. Cod.;* Sirupi, *P. G.;* Sirupe, *G.;* Sciroppi, *It.;* Jarabe, *Sp.*

Syrups are concentrated solutions of sugar in aqueous fluids, either with or without the addition of medicating or flavoring ingredients. When the solution is made with pure water, it is named *syrup* or *simple syrup;* when charged with one or more medicinal agents, it is called in general terms a *medicated syrup,* and receives its special designation from the substance or substances added.

Medicated syrups are prepared by dissolving sugar in infusions, vinegars, decoctions, expressed juices, fermented liquors, or simple aqueous solutions, or by adding a medicating substance, like a tincture or a fluidextract, to simple syrup. When the active constituents are not readily soluble in water, are associated with soluble matter which it is desirable to avoid, or are volatilized or decomposed by a heat of 100° C., they are sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off.

The process of percolation has been applied for the solution of the sugar and is offered as an alternative process in a few official preparations. This process offers several advantages over the older methods. The amount of labor attending the operation is greatly reduced, no heat is employed so that volatile constituents are not injured, and the finished syrup comes through clear and is protected from the usual contaminations attending straining, etc. For the mode of properly conducting this process the reader is referred to page 1062.

The quality and quantity of the sugar employed are points of importance. Official granulated sugar should always be employed.

In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The Pharmacopœial formula calls for 850 Gm. of sugar to make 1000 cc. of syrup, the amount of water required being about 465 cc. This makes a stable preparation.

Syrups as formerly made by more or less empiric methods, checked finally by the use of a hydrometer (saccharimeter) have been replaced by those prepared according to definite procedure and affording products of uniformity.

When carefully prepared with the best refined sugar, syrups made by the hot process or by agitation in the cold usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a rule, to remove the scum as it rises during the heating process, and to strain the syrup while hot through muslin or flannel. The percolation process avoids this necessity. Should syrups at any time lack the due degree of transparency, they may be filtered through paper if a hot water funnel is used, or, when likely to be injured by this treatment, may be clarified by other mechanical means, as mentioned under the head of *Syrupus*. The vicious habit practised not long ago by sugar refiners of "blueing" sugars by the use of ultramarine and other coloring agents has been discontinued by most sugar refiners. (See *A. J. P.*, 1901, 119.)

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups always contain invert sugar. Even at ordinary temperatures, acids in any amount, however small, slowly convert common sugar into invert sugar, which, being less soluble than the former, is often deposited in the form of crystalline grains. Excessive acidity soon causes a darkening of the syrup, due to caramelization of the sugar. Syrups containing too little sugar are subject to fermentation upon accidental inoculation with yeast cells which almost invariably occurs. Syrups sometimes undergo changes in which moulds are produced which appear on the surface as isolated colonies or as a continuous film. Those which contain too much, deposit a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. Such syrups which have undergone fermentation or moulding should never be used for pharmaceutical purposes, as no amount of reboiling can render them fit for use.

The percolation method for preparing syrups has come into general use. For some syrups it is to be preferred to the usual method of heating, and all syrups which contain a volatile principle, or one likely to be injured by heat, are preferably made by *percolation*. The details of the official method are given below. It was first recommended that a small piece of sponge should be used to close the lower orifice of the percolator, but this has advantageously been replaced by purified cotton.

To be successful in using the process, care in several particulars must be exercised. (1) The percolator should be cylindrical or semi-cylindrical, and cone-shaped as it nears the lower orifice. (2) The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. (3) The sponge or pledget must be introduced with care. If pressed too tightly in, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (not properly filtered). See also *Bull. Pharm.*, 1902, 1248. For a paper on *Fruit Syrups*, see *West. Drug.*, 1902, 182; *Proc. Penn. Pharm. Assoc.*, 1903, 196.

Syrups may be made rapidly (without heat) by putting the ingredients in a mechanical shaker or stirrer and agitating briskly.

"Rock Candy Syrup," the evaporated mother liquor left after crystallizing sugar in the form of large crystals, called "rock candy," has come largely into use in America. It varies much in quality as made by various manufacturers. It usually consists in part of invert sugar, and often contains added glucose. It should never be used for making the official syrups, and it should always be carefully tested before being used for any purpose. (See analyses by L. F. Kebler, in *A. J. P.*, 1895, 143.)

At best, syrups are apt to change, and various measures have been proposed for their preservation, but the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stoppered, which should be put in the cellar or other cool place. Glycerin is often used to aid in the preservation of syrups; in special cases this may be advantageous, but the solvent properties of glycerin must be remembered, and the finished preparation may possess properties (due to the glycerin) which are not found in syrups made without glycerin, and which may therefore be injurious in prescriptions. (See *West. Drug.*, 1898, 444.)

SYRUPUS. U. S., Br.

SYRUP [Sirup, Simple Syrup]

Syrupus Simplex; Syrupus Sacchari, s. Albus; Sirop de Sucre, Sirop simple, *Fr.*; Sirupus simplex, *P. G.*; Weisser Sirup, *G.*; Sciroppo semplice, *It.*; Jarabe simple, *Sp.*

"Sucrose, 850 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Insert into the neck of a percolator of suitable size a pledget of purified cotton, not too tightly, in such a manner that the cotton shall nearly fill the neck of the percolator, and moisten it with a few drops of distilled water. Place the sucrose in the percolator, make its surface level without shaking or jarring, then carefully pour upon it 450 cc. of distilled water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Collect the liquid in a 1000 cc. graduated container and return portions to the percolator if necessary until all of the sucrose has been dissolved. Then pass enough distilled water through the cotton to make the product measure 1000 cc. and mix thoroughly.

"Syrup may also be prepared in the following manner: Heat 450 cc. of distilled water to boiling, add the sucrose, and continue the heat cautiously, stirring until the sucrose is dissolved and the syrup has a temperature of 100° C. Then filter it through purified cotton and pass enough distilled water through the cotton to make the product measure 1000 cc. when cold.

"Specific gravity: about 1.313 at 25° C." *U. S.*

"Refined Sugar, 1000 *grammes;* Distilled

Water, sufficient to produce 1500 *grammes.* Heat together until dissolved; add sufficient Distilled Water to produce the required weight. Specific gravity 1.330. *Optical rotation* + 56° to + 58°." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavor, thick, viscid, nearly colorless, and perfectly transparent. It sometimes requires straining through muslin or it may be filtered through a pledget of cotton or often through paper.

Colorless "rock candy" forms an excellent source for pure syrup (the broken crystals can be procured cheaply from the manufacturers), and syrup entirely free from impurities is required in making such preparations as syrup of hydriodic acid, syrup of ferrous iodide, etc. Joseph L. Mayer (*J. A. Ph. A.*, 1916, p 712) shows that it is unfair to assume that commercial glucose is present as an adulterant of syrup, simply because it contains reducing sugar, for in a series of experiments conducted by him, working with both cold process and hot process syrups, the amount of invert sugar found after standing for one year, ranged from about 8 per cent. to over 40 per cent., depending entirely on the length of time of standing. Plette (*J. A. Ph. A.*, 1918, vii, 609) has found that, as far as the likelihood of inversion is concerned, there is no advantage in either the hot or cold process but that the change was less rapid if stored in a cold dark place. The grade of granulated sugar known as "crystal A" or as "Druggists' Dry Granular," is used with success in some parts of the country where it can be readily obtained. It is crystallized from the first runnings from the bone-black filters.

Syrup is very useful in the formulation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup is practically identical with that formerly official, being a trifle stronger, the sp. gr. being given as 1.313 at 25° C. That of the Br. syrup is 1.330 at 15.5° C., probably adapted to the climate of Great Britain, which is not so cold in winter as is ours, at least in the Northern and Middle States.

SYRUPUS ACIDI CITRICI. U. S.

SYRUP OF CITRIC ACID Syr. Acid. Cit.

Acidi Citri Sirupus; Syrupus Limonis, *Fr. Cod.;* Sirop d'Acide Citrique, Sirop Citrique, *Fr.;* Citronensaüre-sirup, *G.*

"Tincture of Lemon Peel, 10 cc.; Citric Acid, 10 Gm.; Distilled Water, 10 cc.; Syrup, a sufficient quantity to make 1000 cc. Dissolve the citric acid in the distilled water and mix the solution with 950 cc. of syrup. Add the tincture and enough syrup to make the product measure 1000 cc. Mix thoroughly. This preparation must not be dispensed if it has a terebinthinate odor or taste or shows other deterioration.

"Preserve in containers which have previously been washed with boiling water." *U. S.*

Syrup of citric acid is used solely as a vehicle. The British and several of the European Pharmacopœias still direct a syrup made from lemon juice. While this may have some advantage on the question of palatability it is so unstable that the U. S. Pharmacopœia, together with those of France, Belgium, etc., have used an "artificial" lemonade; in some of the Pharmacopœias the name of lemon syrup (or its foreign equivalent) is still retained, but in this country it would be illegal to so designate this preparation. The formula for the former U. S. syrup of lemon is given under *Syrupus Limonis.*

SYRUPUS ACIDI HYDRIODICI. U. S., Br.

SYRUP OF HYDRIODIC ACID Syr. Acid. Hydriod.

"Syrup of Hydriodic Acid contains not less than 1.3 Gm. and not more than 1.5 Gm. of HI in each 100 cc." *U. S.*

Sirop d'Acide Iodhydrique, *Fr.;* Jodwasserstoffsirup, *G.*

"Diluted Hydriodic Acid, 130 cc.; Sucrose, 450 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Mix the diluted hydriodic acid with 550 cc. of distilled water and dissolve the sucrose in this mixture by agitation. Add sufficient distilled water to make the product measure 1000 cc., and filter." *U. S.*

"Diluted Hydriodic Acid, 100 *grammes;* Distilled Water, 50 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

An unprotected aqueous solution of hydriodic acid is frequently unstable, the iodine being in time liberated, rendering it irritant and unfit for internal administration, and as it has been proved that syrup protects the acid efficiently, the 1880 Committee of Revision introduced the Syrup of Hydriodic Acid, with the view of furnishing a preparation which should remain if properly made and carefully preserved, for a long time unchanged. In the U. S. P. the syrup is made by dissolving sugar in diluted hydriodic acid and adding water, it having been proved that diluted hydriodic acid could be made so as to be reasonably permanent (see *Acidum Hydriodicum Dilutum*). Diluted simple syrup has been proved to make a more permanent syrup of hydriodic acid than syrup. Unofficial and proprietary forms of syrup of hydriodic acid are found in the market in which glycerin or glucose is the principal diluting constituent, the reason being given that the presence of these ingredients prevents discoloration. (*Proc. A. Ph. A.*, 1897, 221.)

Properties.—"A transparent, colorless, or not more than pale, straw-colored, odorless, syrupy liquid, having a sweet and acidulous taste. Specific gravity: about 1.185 at 25° C. Mix 5 cc. of Syrup of Hydriodic Acid with a few drops of starch T.S. and add 3 drops of chlorine T.S.: the liquid acquires a deep blue color. No blue color is produced in the syrup by starch T.S. alone (*free iodine*).

"**Assay.**—Place exactly 25 cc. of Syrup of

Hydriodic Acid in a flask, dilute it with 100 cc. of distilled water, add 40 cc. of tenth-normal silver nitrate, agitate the mixture, add 5 cc. of diluted nitric acid and 2 cc. of ferric ammonium sulphate T.S., and determine the residual silver nitrate by titration with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.01279 Gm. of HI." *U. S.*

Uses.—Syrup of hydriodic acid possesses the general therapeutic properties of the iodides, and is used by various practitioners to obtain alterative effects in *scrofula* and similar disorders. As it contains 1.4 per cent. by weight of absolute hydriodic acid, for practical purposes a teaspoonful may be said to represent about 0.75 of a grain of iodine or a little over 1 grain of potassium iodide. It is evident that the doses in which it is usually administered—from twenty to forty minims (1.3–2.5 cc.)—are too small. It should be well diluted at the time of administration, to prevent the possibility of injury to the teeth.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

SYRUPUS AROMATICUS. Br.

AROMATIC SYRUP

Sirop Aromatique, *Fr.;* Aromatischer Sirup, *G.*

"Tincture of Orange, 250 *millilitres;* Cinnamon Water, 250 *millilitres;* Syrup, 500 *millilitres.* Mix the Tincture of Orange and Cinnamon Water; shake the mixture with a little *powdered talc;* filter; add the Syrup." *Br.*

This preparation of the Br. Ph., 1898, is practically a simple elixir (see *Elixir Aromaticum*); it has been introduced mainly as a vehicle or adjuvant.

SYRUPUS AURANTII. U. S., Br.

SYRUP OF ORANGE Syr. Aurant.

Syrup of Orange Peel; Sirop d'Ecorce d'Orange amère, *Fr.;* Sirupus Aurantii Corticis, *P. G.;* Pomeranzenschalensirup, Orangenschalensyrup, *G.;* Sciroppo di arancio, *It.;* Jarabe de corteza de naranja, *Sp.*

"Tincture of Sweet Orange Peel, 50 cc.; Citric Acid, 5 Gm.; Purified Talc, 15 Gm.; Sucrose, 820 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Triturate the purified talc with the tincture and citric acid, and gradually add 400 cc. of distilled water. Then filter, returning the first portions of the filtrate until it becomes clear, and wash the mortar and filter with enough distilled water to make the filtrate measure 450 cc. Dissolve the sucrose in this filtrate by agitation, and add enough distilled water to make the product measure 1000 cc. Mix thoroughly and strain. This preparation must not be dispensed if it has a terebinthinate odor or taste or shows other deterioration.

"Alcohol content, by volume, 2 to 5 per cent." *U. S.*

"Tincture of Orange, 125 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

The present U. S. process is an improvement over preceding formulas as the flavor is derived from the tincture of fresh orange peel and the alkaline magnesium carbonate of the U. S. P. VIII, which modified the flavor, has been replaced by inert talc, the latter being used as a distributing and filtering medium. The British preparation, which is a mere mixture of the tincture with syrup, is inferior. The syrup has an agreeable, slightly acid flavor, for which it is alone employed. For a process by E. E. Williams, using powdered pumice to disintegrate the orange peel, see *D. C.*, 1898, 125.

SYRUPUS AURANTII FLORUM. U. S. (Br.)

SYRUP OF ORANGE FLOWERS Syr. Aurant. Flor.

Syrupus Aurantii Floris, *Br.;* Sirop de Fleur d'Oranger, *Fr.;* Pomeranzenblüthensirup, *G.;* Jarabe de azahar, *Sp.*

"Orange Flower Water, 225 cc.; Sucrose, 850 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Mix the orange flower water with 225 cc. of distilled water, dissolve the sucrose in the mixture by agitation, without heat, and add sufficient distilled water to make the product measure 1000 cc. Mix thoroughly and strain. Syrup of Orange Flower Water may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour the mixture of orange flower water and water upon the sucrose, return the first portions of percolate until it runs through clear, and when all of the liquid has run through, follow it with distilled water until the sucrose is dissolved and the product measures 1000 cc. Mix thoroughly." *U. S.*

"Orange-flower water of commerce, undiluted, 150 *millilitres;* Refined Sugar, 300 *grammes;* Syrup, sufficient to produce 1000 *millilitres.* Mix the orange-flower water with the Refined Sugar in a closed vessel; stand in a moderately warm place, shaking occasionally till dissolved; then add sufficient Syrup to produce the required volume." *Br.*

The second U. S. process, by percolation, will be preferable here. This syrup is used chiefly for flavoring mixtures.

SYRUPUS CALCII LACTOPHOSPHATIS. Br.

SYRUP OF CALCIUM LACTOPHOSPHATE Syr. Calc. Lactophos.

Sirop de Lactophosphate (phospholactate) de chaux, *Fr.;* Calciumphospholactatsirup, *G.;* Jarabe de lactofosfato calcico, *Sp.*

"Calcium Lactate, 75 *grammes;* Concentrated Phosphoric Acid, 45 *millilitres;* Orange-flower water of commerce, undiluted, 25 *millilitres;* Refined Sugar, 700 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix the Calcium Lactate with four hundred millilitres of the Distilled Water, add the Concentrated Phosphoric Acid and stir until solution is complete, then add the orange-flower water, dissolve the Refined Sugar in the mixture without the aid of heat, and add sufficient Distilled Water to produce the required volume; filter." *Br.*

The U. S. no longer recognizes this syrup but a similar preparation has been admitted to the N. F. (see Part III).

This preparation is based upon the fact that freshly precipitated calcium phosphate is soluble in the presence of lactic acid. The calcium phosphate which is at first precipitated by the action between calcium lactate and the first portion of phosphoric acid is redissolved as more acid is added. The syrup sometimes deposits a gelatinous precipitate on keeping, which can usually be avoided by the addition of a small amount of hydrochloric acid. Calcium lactophosphate in the solid form is also recognized by the N. F. and is described elsewhere.

Dose, from one-half to one fluidrachm (2–4 cc.), representing from three to six grains of the lime salt.

Off. Prep.—Elixir Cinchonæ Alkaloidorum, Ferri, et Calcii Lactophosphatis, *N. F.;* Syrupus Calcii Lactophosphatis et Ferri, *N. F.*

SYRUPUS CASCARÆ AROMATICUS. Br.

AROMATIC SYRUP OF CASCARA

Sirop aromatique de Cascara Sagrada, *Fr.;* Aromatischer Amerikanisch-Faulbaumrindensirup, *G.*

"Liquid Extract of Cascara Sagrada, 400 *millilitres;* Tincture of Orange, 100 *millilitres,* Alcohol (90 per cent.), 50 *millilitres;* Cinnamon Water, 150 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

This was a new syrup in the Br. Pharm., 1898. It forms a convenient means of administering cascara, the alcohol being added to aid its preservation.

Dose, from one-half to two fluidrachms (1.8–7.5 cc.).

SYRUPUS CHLORAL. Br.

SYRUP OF CHLORAL

Sirop de Chloral, *Fr.;* Chloralhydratsirup, *G.;* Jarabe de hidrato de cloral, *Sp.*

"Chloral Hydrate, 200 *grammes;* Distilled Water, 200 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Dissolve the Chloral Hydrate in the Distilled Water; add sufficient Syrup to produce the required volume. 10 millilitres of this Syrup contain 2 grammes of Chloral Hydrate; 1 fluid drachm contains 10.9 grains." *Br.*

Dose, one to two fluidrachms (3.75–7.5 cc.).

SYRUPUS CODEINÆ PHOSPHATIS. Br.

SYRUP OF CODEINE PHOSPHATE

Sirop de Codéine, *Fr.;* Kodeinsirup, *G.;* Sciroppo di codeina, *It.;* Jarabe de codeina, *Sp.*

"Codeine Phosphate, 5 *grammes;* Distilled Water, 15 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Dissolve the Codeine Phosphate in the Distilled Water; add sufficient Syrup to produce the required volume. 10 millilitres of this Syrup contain 0.05 gramme of Codeine Phosphate; 1 fluid drachm contains 0.27 grain." *Br.*

This syrup is intended to furnish a convenient method of using codeine phosphate. A syrup of codeine, made from the sulphate is official in the N. F. (see *Syrupus Codeinæ,* Part III).

Dose, one-half to two fluidrachms (1.8–7.5 cc.).

SYRUPUS FERRI IODIDI. U. S., Br.

SYRUP OF FERROUS IODIDE Syr. Ferr. Iod. [Ferri iodidi syrupus P. I.]

"Syrup of Ferrous Iodide contains not less than 6.5 Gm. and not more than 7.5 Gm. of FeI_2 in each 100 cc., representing approximately 5 per cent. of FeI_2, by weight." *U. S.*

Syrup of Iodide of Iron; Syrupus Ferri Iodati Gallicus, *Fr. Cod.;* Sirop d'Iodure de fer, *Fr.;* Syrupus Ferri Jodati, *P. G.;* Eisenjodürsirup, *G.;* Sciroppo di protojoduro di ferro, *It.;* Jarabe de yoduro ferroso, *Sp.*

"Iron in the form of fine, bright wire, 20 Gm.; Iodine, 60 Gm.; Hypophosphorous Acid, 5 cc.; Sucrose, 850 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Place the iron in a flask having a capacity of about 500 cc., add the iodine and 200 cc. of distilled water, and shake the mixture occasionally, checking the reaction if necessary by placing the flask in cold water. When the liquid has acquired a green color and has lost the odor of iodine, heat it to boiling, and dissolve 100 Gm. of sucrose in hot liquid. Filter the solution at once into a flask, graduated to 1000 cc. and containing the remainder of the sucrose, and rinse the flask containing the iron with 240 cc. of hot distilled water, in divided portions, passing the rinsings successively through the filter. Agitate the mixture until the sucrose is dissolved, warming if necessary, cool to 25° C., add the hypophosphorous acid and enough distilled water to make the product measure 1000 cc. Mix well and strain." *U. S.*

"Iron, in wire, 15.0 *grammes;* Iodine, 41.4 *grammes;* Distilled Water, 75.0 *millilitres;* Glucose, 100.0 *grammes;* Syrup, sufficient to produce 1000.0 *grammes.* Add the Iron and the Iodine to fifty millilitres of the Distilled Water in a flask; shake occasionally, cooling if necessary. When the reaction is completed add the Glucose, heat on a water-bath for five minutes, mix, and while still hot filter into a tared vessel containing part of the Syrup. Rinse the flask and wash the filter-paper with the remaining twenty-five millilitres of the Distilled Water heated to boiling; add sufficient Syrup to produce the required weight." *Br.*

W. G. Toplis (*Proc. Penna. Pharm. Assn.,* 1916, p. 243) substitutes *Ferrum Reductum* for the card teeth officially directed in this process, with the result that the solution can be effected, ready for filtration, in less than ten minutes, working with the official proportions.

Properties.—"A transparent, pale yellowish-green, syrupy liquid, having a sweet, strongly ferruginous taste and slightly acid reaction. Specific gravity: about 1.37 at 25° C. Add a few drops of potassium ferricyanide T.S. to

5 cc. of Syrup of Ferrous Iodide: a blue precipitate is produced. Mix 5 cc. of Syrup of Ferrous Iodide with a few drops of starch T.S. and add three drops of chlorine T.S.; the liquid acquires a deep blue color. No blue color is produced in Syrup of Ferrous Iodide by starch T.S. alone (*free iodine*).

"**Assay.**—Place exactly 10 cc. of Syrup of Ferrous Iodide in a flask, dilute it with 30 cc. of distilled water, add 50 cc. of tenth-normal silver nitrate and 5 cc. of nitric acid, and heat on a water bath until the precipitate of silver iodide is yellow. Cool, add 2 cc. of ferric ammonium sulphate T. S., and determine the residual silver nitrate by titration with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.01548 Gm. of FeI_2.

"Preserve in completely filled, tightly-stoppered bottles." *U. S.*

"When 5 grammes of the Syrup are diluted with 20 millilitres of *water*, acidified with *nitric acid* and mixed with 20 millilitres of *N/10 solution of silver nitrate*, not less than 3.5 or more than 4.2 millilitres of *N/10 solution of ammonium thiocyanate* are required to produce a permanent red coloration, *solution of ferric sulphate* being used as indicator, corresponding to not less than 4.9 and not more than 5.1 grammes of ferrous iodide, FeI_2, in 100 grammes of the Syrup. 10 millilitres of this Syrup contain about 0.7 gramme of ferrous iodide; 1 fluid drachm contains 3.75 grains. It is of the strength required by the International Agreement, and is approximately of two-thirds the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

When the syrup is concentrated it becomes brown, and when evaporated to dryness forms a mass which may be called *saccharine ferrous iodide*, and which is not entirely soluble again, a little ferric oxide being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt (see *Ferrous Iodide*, Part II), and may be made into pills. (See *U. S. D.*, 19th ed., p. 1225, for *Ferri Iodidum Saccharatum.*)

Notes on examination of market samples and conclusions and recommendations as to methods of preservation, keeping qualities, etc., have been published by the following authors: L. A. Brown, *Proc. Ky. Ph. Assn.*, 1914, 61; W. C. Alpers, *J. A. Ph. A.*, 1914, 420; G. M. Beringer, *J. A. Ph. A.*, 1914, 970.

Uses.—Syrup of ferrous iodide combines the alterative action of iodine with the hematinic action of iron. It is a popular remedy in chronic types of *tuberculosis*, especially in the *scrofula* of children. It has, however, no advantage over an extemporaneous combination of an iodine with ferruginous tonic, and has the drawback that the dose of either ingredient cannot be altered singly.

Dose, for an adult, ten to forty minims (0.6–2.5 cc.); for a child of two years, two to eight minims (0.12–0.5 cc.).

SYRUPUS FERRI PHOSPHATIS. Br.

SYRUP OF FERROUS PHOSPHATE

Sirop de Phosphate de Fer, *Fr.;* Eisenphosphatsirup, *G.*

"Iron, in wire, 8.6 *grammes;* Concentrated Phosphoric Acid, 62.5 *millilitres;* Syrup, 700.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Dilute the Concentrated Phosphoric Acid with an equal volume of Distilled Water in a small flask; add the Iron and heat very gently until dissolved. Filter into the Syrup, and pass sufficient Distilled Water through the filter to produce the required volume. 10 millilitres of this Syrup contain 0.17 gramme of anhydrous ferrous phosphate; 1 fluid drachm contains 1 grain." *Br.*

R. Wright (*P. J.*, 1893, 191) improved the formula, and this method is superior to the former cumbersome process of preparing a precipitate of ferric phosphate, and dissolving it in phosphoric acid. The syrup is a solution of ferrous phosphate protected by sugar. The sp. gr. is about 1.270. (Umney.) For its properties and uses, see *Ferri Phosphas.*

Dose, from one to two fluidrachms (3.75–7.5 cc.).

SYRUPUS FERRI PHOSPHATIS CUM QUININA ET STRYCHNINA. Br.

SYRUP OF PHOSPHATE OF IRON WITH QUININE AND STRYCHNINE

Easton's Syrup; Sirop Tonique d'Easton, *Fr.;* Eisenphosphatsirup mit Chinin und Strychnin, Eastonscher Sirup, *G.*

"Iron, in wire, 8.60 *grammes;* Concentrated Phosphoric Acid, 62.50 *millilitres;* Strychnine, in powder, 0.57 *gramme;* Quinine Sulphate, 14.80 *grammes;* Syrup, 700.00 *millilitres;* Distilled Water, sufficient to produce 1000.00 *millilitres.* Dilute the Concentrated Phosphoric Acid with an equal volume of Distilled Water in a small flask; add the Iron and heat very gently until dissolved; add the solution to the Strychnine and Quinine Sulphate previously triturated with thirty millilitres of the Distilled Water; when solution is complete filter the Syrup, and pass sufficient Distilled Water through the filter to produce the required volume. 10 millilitres of this Syrup contain 0.17 gramme of anhydrous ferrous phosphate, 0.148 gramme of Quinine Sulphate, and 0.057 gramme of Strychnine; 1 fluid drachm contains 1 grain of anhydrous ferrous phosphate, 4/5 grain of Quinine Sulphate, and 1/32 grain of Strychnine." *Br.*

This syrup is not official in the U. S. P. but a similar preparation is recognized by the N. F. (see Part III).

Uses.—This syrup has the medicinal activities of its ingredients, but is a very ineligible preparation, and has not even an agreeable taste to excuse its polypharmacy. It is known as *Easton's Syrup, Aitkin's Syrup, Syrup of* *the Three Phosphates,* and *Syrup of Triple Phosphates.*

Dose, one to two fluidrachms (3.75–7.5 cc.).

SYRUPUS GLUCOSI. Br.

SYRUP OF GLUCOSE

"Glucose, 250 *grammes;* Syrup, 500 *grammes.* Mix, by the aid of gentle heat." *Br.*

Sirop de Glycose, *Fr.;* Glykosesirup, *G.*

This was a new preparation of the Br. Ph., 1898. It may be used as a vehicle for syrups which contain chemical salts liable to discoloration through the action of light, but its principal use is to take the place of *treacle* or molasses so much used in British pharmacy as a pill excipient. (See *Pilulæ.*)

SYRUPUS IPECACUANHÆ. U. S.

SYRUP OF IPECAC Syr. Ipecac.

Sirop d'Ipécacuanha, *Fr. Cod.;* Sirupus Ipecacuanhæ, *P. G.;* Brechwurzelsirup, Ipecacuanhasirup, *G.;* Sciroppo di ipecacuanha, *It.;* Jarabe de Ipecacuana, *Sp.*

"Fluidextract of Ipecac, 70 cc.; Glycerin, 100 cc.; Syrup, a sufficient quantity to make 1000 cc. Mix the fluidextract with the glycerin, and add enough syrup to make the product measure 1000 cc. Mix thoroughly.

"Alcohol content, by volume, 1.5 to 2 per cent." *U. S.*

If strictly official fluidextract of ipecac is used in making this syrup, and the process is carried out in all its details, the syrup will remain transparent; but with fluidextracts which are not carefully made it may be necessary to allow the diluted fluidextract in the official process for making this syrup to remain for two or three days in a cool place before filtering, and adding to the sugar.

Although this syrup possesses all the virtues of ipecac, it is used almost exclusively as a nauseating expectorant in *acute bronchitis.*

Dose, for an adult, as an expectorant, from fifteen to thirty minims (0.9–1.8 cc.); as an emetic, half a fluidounce (15 cc.).

SYRUPUS LIMONIS. Br.

SYRUP OF LEMON

Syrupus Succus Citri; Sirop de Limon (de Citron), Sirop de suc de Limon (de citron), *Fr.;* Citronensirup, Citronensaftsirup, *G.;* Jarabe de limon, *Sp.*

"Lemon Peel, in thin slices or grated, 20 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Lemon Juice, 500 *millilitres;* Refined Sugar, 760 *grammes.* Macerate the Lemon Peel in thirty millilitres of the Alcohol for seven days; press; filter; add sufficient of the Alcohol to produce forty millilitres. In the Lemon Juice, clarified by subsidence or filtration, dissolve the Refined Sugar by the aid of gentle heat; cool; add the forty millilitres of alcoholic liquid; mix." *Br.*

The U. S. P. 1880 syrup of lemon was dropped at the 1890 revision; as it is frequently used, the process is appended.

"Lemon Juice, recently expressed and strained, *forty parts;* Fresh Lemon Peel, *two parts;* Sugar, in coarse powder, *sixty parts;* Water *a sufficient quantity,* to make *one hundred parts.* Heat the Lemon Juice to the boiling point; then add the Lemon Peel, and let the whole stand, closely covered, until cold. Filter, add enough Water through the filter to make the filtrate weigh *forty parts,* dissolve the Sugar in the filtered liquid by agitation, without heat, and strain." *U. S.* 1880.

The addition of lemon peel to the preparation is an improvement, but the internal white portion of the peel should be carefully removed before adding to the hot lemon juice, or the finished syrup will have a bitter taste. (See *Limonis Cortex.*) This syrup forms a cooling and grateful addition to beverages in *febrile complaints,* and serves to conceal the taste of saline purgatives in solution.

SYRUPUS PICIS PINI. U. S.

SYRUP OF PINE TAR Syr. Pic. Pin. [Syrupus Picis Liquidæ U. S. P. IX, Syrup of Tar]

Syrupus Piceus; Sirop de Goudron, *Fr.;* Theersirup, *G.;* Jarabe de Brea, *Sp.*

"Rectified Oil of Tar, 1 cc.; Sucrose, 850 Gm.; Water, a sufficient quantity to make 1000 cc. Mix the oil with 450 cc. of water and agitate the mixture frequently during fifteen minutes. Then set aside for twenty-four hours, shaking it occasionally during that time. Filter, dissolve the sucrose in the clear filtrate, and add sufficient water to make the product measure 1000 cc. Mix thoroughly and strain." *U. S.*

This syrup has been improved by substituting in the place of tar itself, which was used in the U. S. IX, the liquid distillate known as oil of tar, which probably represents all the therapeutic virtues of the tar. Theoretically a teaspoonful of the syrup should represent approximately 1 minim of the oil of tar, but as this is not completely soluble in water and the undissolved portion is removed by filtration, the amount of active ingredient, will be somewhat less.

The change in this formula was made after considerable experimentation, in which it was found that when made from oil of tar the preparation possesses a pronounced odor and taste of tar, and the after taste is free from acridity.

Comparative tests showed the proportion of dissolved principles of tar to be greater in the preparation made from the oil by the present method, than in the preparation as formerly made from tar itself.

Syrup of tar is a popular stimulating expectorant in the milder forms of sub-acute or chronic *bronchitis.* In the doses ordinarily employed the quantity of active ingredient is, however, so small that the preparation can have scarcely any effect except as a flavoring agent.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

SYRUPUS PRUNI VIRGINIANÆ.
U. S., Br.

SYRUP OF WILD CHERRY Syr. Prun. Virg.

Syrup of Virginian Prune, *Br.* 1898; Sirop d'Ecorce de Cerisier, *Fr.;* Wildkirschenrindensirup, *G.*

"Wild Cherry, in coarse powder, 150 Gm.; Sucrose, 800 Gm.; Glycerin, 50 cc.; Water, a sufficient quantity to make 1000 cc. Mix the glycerin with 200 cc. of water, moisten the wild cherry with 100 cc. of this mixture, pack it in a cylindrical percolator and pour the remaining 150 cc. of menstruum upon it. When this has disappeared from the surface of the drug, add enough water to saturate the powder and leave a stratum above it. Close the lower orifice, cover the percolator, and macerate the drug for twenty-four hours. Then allow the percolation to proceed slowly, allowing the percolate to drop into the sucrose contained in a bottle graduated to 1000 cc. and having a capacity of 2000 cc. Add enough water, as the menstruum, to make the combined sucrose and percolate measure 1000 cc., stopper the bottle, and dissolve the sucrose by agitation without heat. Restore the volume by adding enough water to make the product measure 1000 cc., and strain.

"Preserve in tightly-stoppered bottles, in a cool place." *U. S.*

"Wild Cherry Bark, in No. 20 powder, 150 *grammes;* Refined Sugar, in coarse powder, 750 *grammes;* Glycerin, 65 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Moisten the Wild Cherry Bark with Distilled Water; set aside for twenty-four hours in a closed vessel; pack in a percolator; percolate with Distilled Water until four hundred and fifty millilitres have been collected; dissolve the Refined Sugar in the percolated liquid, without heat; add the Glycerin and sufficient Distilled Water to produce the required volume." *Br.*

The British Pharmacopœia introduced this syrup into the 1898 edition. The process is modelled after the U. S. formula.

The U. S. process affords a handsome syrup with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Procter and Turnpenny in *A. J. P.,* xiv, 27. The introduction of the glycerin into the receiving bottle instead of mixing it with the menstruum was dropped in the process of the U. S. P. The glycerin is not needed in the menstruum to increase the astringency of the syrup but it serves a useful purpose in keeping the infusion from decomposing and precipitating a reddish, insoluble substance in the receiving bottle. This syrup should never be made by adding fluidextract to simple syrup, as the fluidextract is likely to vary greatly in quality, and frequently precipitates when mixed with syrup, the syrup when made by the above process is far superior in flavor. It is largely used as a vehicle for cough mixtures.

Dose, one to four fluidrachms (3.75–15.0 cc.).

SYRUPUS RHEI. U. S., Br.

SYRUP OF RHUBARB Syr. Rhei

Sirop de Rhubarbe, *Fr.;* Sirupus Rhei, *P. G.;* Rhabarbersirup, Rhabarbersaft, *G.*

"Fluidextract of Rhubarb, 100 cc.; Spirit of Cinnamon, 4 cc.; Potassium Carbonate, 10 Gm.; Water, 50 cc.; Syrup, a sufficient quantity to make 1000 cc. Mix the spirit of cinnamon with the fluidextract, add the potassium carbonate, previously dissolved in the water, and add to this mixture enough syrup to make the product measure 1000 cc.

"Alcohol content, by volume, 5 to 6 per cent." *U. S.*

"Rhubarb, in No. 20 powder, 70.0 *grammes;* Oil of Coriander, 0.5 *millilitre;* Refined Sugar, 840.0 *grammes;* Alcohol (90 per cent.), 280.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Mix two hundred and seventy millilitres of the Alcohol with three times its volume of Distilled Water. Moisten the Rhubarb with seventy millilitres of this diluted alcohol and set aside for twenty-four hours in a closed vessel; pack in a percolator; pass the remainder of the diluted alcohol slowly through the moistened powder; evaporate the percolate to four hundred and seventy-five grammes; filter; dissolve the Refined Sugar in the filtrate by the aid of heat; cool; add the Oil of Coriander dissolved in ten millilitres of the Alcohol; mix, and finally add sufficient Distilled Water to produce the required volume." *Br.*

The Br. process is a troublesome and imperfect method.

The U. S. syrup differs from that official before 1890 in several particulars, and, in our opinion, it is greatly improved; the activity of the rhubarb and the corrigent effects of the cinnamon are both secured without impairing the appearance of the finished syrup, while the simplicity of the manipulation must commend the process to all. In the Br. Pharm., 1914, oil of coriander replaced coriander fruit official in the former pharmacopœia.

The official syrup is a mild cathartic, adapted for use with infants, to whom it may be given in the dose of a fluidrachm (3.75 cc.).

Dose, for adults, two to three fluidrachms (7.5–11.25 cc.).

SYRUPUS RHEI AROMATICUS. U. S.

AROMATIC SYRUP OF RHUBARB Syr. Rhei Arom.
[Spiced Syrup of Rhubarb]

Sirop de Rhubarbe aromatique, *Fr.;* Gewürzter Rhabarbersaft, *G.*

"Aromatic Tincture of Rhubarb, 150 cc.; Potassium Carbonate, 1 Gm.; Syrup, a sufficient quantity to make 1000 cc. Dissolve the potassium carbonate in the tincture and add to the mixture enough syrup to make the product measure 1000 cc. Mix thoroughly.

"Alcohol content, by volume, 6 to 7 per cent." *U. S.*

A small amount of alkali is added here to prevent the syrup from becoming turbid.

The *aromatic syrup of rhubarb* is a warm stomachic laxative, too feeble for adult cases, chiefly used for the bowel complaints of infants, which are so frequent in our cities during the summer season. This preparation, or one analogous to it, has been long in use, under the name of *spiced syrup of rhubarb*. The dose for an infant with *diarrhea* is a fluidrachm (3.75 cc.), repeated every two hours until the passages indicate by their color that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains about 7 per cent. alcohol, which, though not injurious in most cases in which this syrup is used, might render it too stimulating in the very young infant.

Dose, one to three fluidrachms (3.75–11.25 cc.).

SYRUPUS RHŒADOS. Br.

SYRUP OF RED POPPY

Sirop de Coquelicot, *Fr. Cod.;* Sirop de Pavot rouge, *Fr.;* Klatschrosensaft, *G.*

"Red-Poppy Petals, 260 *grammes;* Refined Sugar, 720 *grammes;* Alcohol (90 per cent.), 50 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Add the Red-poppy Petals gradually to four hundred millilitres of Distilled Water kept hot upon a water-bath, stir frequently, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquid; strain; add the Refined Sugar, and dissolve by the aid of heat. When nearly cold, add the Alcohol, and sufficient Distilled Water to produce the required volume." *Br.*

The object of introducing the petals into water heated by a water bath is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red color of this syrup is its only recommendation. It is very liable to ferment; according to Enders, this can be obviated by evaporating the recently prepared syrup to dryness, keeping the powdered residue in well-stoppered bottles, and dissolving it, as wanted, in four-fifths of its weight of water.

Dose, as stated in the Br. Pharmacopœia, one-half to one fluidrachm (1.8–3.75 cc.).

SYRUPUS ROSÆ. Br.

SYRUP OF ROSE

Syrup of Roses; Syrupus Rosarum Rubrarum; Syrup of Red Rose; Sirop de Rose rouge, *Fr.;* Rosensirup, *G.*

Syrup of Rose was deleted from the U. S. P. IX, but the process was introduced into the National Formulary (see Part III).

"Dried Red-Rose Petals, 50 *grammes;* Refined Sugar, *a sufficient quantity;* Distilled Water, boiling, 500 *millilitres.* Infuse the Red-Rose Petals in the Distilled Water for two hours; strain; press; heat the infusion to the boiling point; filter; add to the filtrate twice its weight of Refined Sugar and dissolve by the aid of heat." *Br.*

Syrup of rose is mildly astringent, but is valued most for its fine red color, on account of which it is occasionally added to mixtures. The color is developed by the small amount of diluted sulphuric acid which is added.

Dose, a fluidrachm (3.75 cc.).

SYRUPUS SARSAPARILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SARSAPARILLA

Syr. Sarsap. Co.

Syrupus Sudorificus; Sirop de Salsepareille composé, *Fr. Cod.;* Sirop de Cuisinier, Sirop sudorifique, *Fr.;* Zusammengesetzter Sarsaparillsirup, *G.;* Jarabe de zarzaparrilla compuesto, *Sp.*

"Fluidextract of Sarsaparilla, 200.0 cc.; Fluidextract of Glycyrrhiza, 15.0 cc.; Oil of Sassafras, 0.2 cc.; Oil of Anise, 0.2 cc.; Methyl Salicylate, 0.2 cc.; Alcohol, 19.4 cc.; Syrup, 765.0 cc.; to make about 1000 cc. Mix the fluidextracts and add the alcohol, in which the methyl salicylate and the oils have been dissolved. Gradually add this solution to the syrup, and mix thoroughly.

"Alcohol content, by volume, 7.5 to 8.5 per cent." *U. S.*

In the original edition of the U. S. Pharmacopœia, published in 1820, a process for a syrup of sarsaparilla was adopted, intended to present the famous French *sirop de cuisinier.* This process has been variously modified from time to time, but the present preparation possesses any possible therapeutic virtues of the original preparation.

The preparation for years contained senna as one of its active constituents. This has now been omitted as unnecessary and even objectionable.

Uses.—The day has gone by when compound syrup of sarsaparilla is regarded by the medical profession as an active therapeutic agent. It has, however, a wide and proper use as a vehicle especially for the iodides and other saline drugs. It is also widely employed, especially in extemporaneous mixtures, to mitigate the unpleasant flavor of castor oil.

Kennedy (*Ph. Rec.,* 1888, 201) has shown that corrosive sublimate invariably yields a precipitate with this syrup, which he asserts may be prevented by the addition of sodium chloride. Potassium-mercuric iodide, which will be formed in the very frequently prescribed extemporaneous mixtures of corrosive sublimate, potassium iodide and compound syrup of sarsaparilla, does not form any such precipitate.

Off. Prep.—Syrupus Bromidorum, *N. F.*

SYRUPUS SCILLÆ, U. S., Br.

SYRUP OF SQUILL Syr. Scill.

Syrupus Aceti Scillæ; Sirop de Scille, *Fr.;* Meerzwiebelsirup, *G.*

"Vinegar of Squill, 450 cc.; Sucrose, 800 Gm.; Water, a sufficient quantity to make 1000 cc. Dissolve the sucrose in the vinegar of squill with the aid of a gentle heat, strain the syrup, and, when cold, add enough water through the strainer to make the product measure 1000 cc. Mix thoroughly." *U. S.*

"Vinegar of Squill, 175 *millilitres;* Refined Sugar, 650 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Mix the Vinegar of Squill with an equal volume of Distilled Water. In the mixture dissolve the refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." *Br.*

The heating should be performed as quickly as possible, to prevent undue loss of acetic acid.

The difference between the U. S. and Br. syrups is not so great as would seem from their formulas, because the British vinegar of squill is much stronger than the American.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. It is incompatible with ammonium carbonate, but not with ammonium chloride.

Dose, about from one-half to one fluidrachm (2–4 cc.).

SYRUPUS SCILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SQUILL Syr. Scill. Co. [Hive Syrup]

Coxe's Hive Syrup; Sirop de Scille composé, *Fr.;* Zusammengesetzter Meerzwiebelsirup, *G.*

"Fluidextract of Squill, 80 cc.; Fluidextract of Senega, 80 cc.; Antimony and Potassium Tartrate, 2 Gm.; Sucrose, 720 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Dissolve the antimony and potassium tartrate in 360 cc. of distilled water, add the fluidextracts, and allow the mixture to stand for twelve hours with occasional shaking. Filter, dissolve the sucrose in the clear filtrate by agitation, and add sufficient distilled water to make the product measure 1000 cc. Mix thoroughly and strain.

"Alcohol content, by volume, 7 to 8 per cent." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive syrup,* from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed it invariably fermented from the want of sufficient concentration. The present formula is a decided improvement, fluidextracts of squill and senega being used. Percolation has been found very well adapted for dissolving the sugar and producing a transparent syrup. The present U. S. P. process has the merit of simplicity, but, unfortunately, the fluidextract of squill is never a wholly satisfactory preparation.

Compound syrup of squill was introduced into medicine a century ago by Dr. J. Redmond Coxe as a remedy for *croup,* which was then called "hives." It has been official in the U. S. since 1840. It has expectorant and diaphoretic properties, both of which depend upon its nauseating action, but in our opinion the use of drugs possessing such powerful systemic actions as do squill and antimony for their nauseating effect, especially in children, is not to be commended. The dose of this syrup for children is from two to twenty minims (0.12–1.3 cc.), according to the age, and it may be repeated in cases of croup every fifteen or twenty minutes until it causes vomiting.

Dose, for adults as an expectorant, from twenty to thirty minims (1.3–1.8 cc.).

SYRUPUS SENEGÆ. U. S.

SYRUP OF SENEGA Syr. Seneg.

Sirop de Polygala, *Fr.;* Sirupus Senegae, *P. G.;* Senegasirup, *G.*

"Fluidextract of Senega, 200 cc.; Ammonia Water, 10 cc.; Syrup, a sufficient quantity to make 1000 cc. Mix the ammonia water with the fluidextract, add the syrup, and mix well.

"Alcohol content, by volume, 9 to 10 per cent." *U. S.*

The syrup affords a very convenient mode of exhibiting senega in pectoral complaints. Owing to the pectinous principle present in senega, the syrup made directly from the root as in the process of 1870 was always turbid. It has been frequently pointed out that the addition of an alkali renders the syrup transparent, and the 1890 process directed the use of a small quantity of ammonia water, although, if the fluidextract of senega which contains alkali be used as in the U. S. P. X, this addition is unnecessary. This syrup may be given as a nauseating expectorant.

Dose, one or two fluidrachms (3.75 or 7.5 cc.).

SYRUPUS SENNÆ. U. S., Br.

SYRUP OF SENNA Syr. Senn.

Sirop de Séné, *Fr.;* Sirupus Sennae, *P. G.;* Sennasirup, *G.*

"Fluidextract of Senega, 250 cc.; Oil of Coriander, 5 cc.; Sucrose, 635 Gm.; Water, a sufficient quantity to make 1000 cc. Mix the oil of coriander with the fluidextract and gradually add 330 cc. of water. Allow the mixture to stand for twenty-four hours in a cool place, with occasional shaking, filter, and pass enough water through the filter to obtain 580 cc. of filtrate. Dissolve the sucrose in this liquid, and add sufficient water to make the product measure 1000 cc. Mix well and strain.

"Alcohol content, by volume, 5.5 to 6.75 per cent." *U. S.*

"Senna Leaves, 440.0 *grammes;* Oil of Coriander, 0.2 *millilitre;* Alcohol (90 per cent.), 2.0 *millilitres;* Refined Sugar, 540.0 *grammes;* Alcohol (20 per cent.), 760.0 *millilitres.* Moisten the Senna Leaves with four hundred and forty millilitres of the Alcohol (20 per cent.); pack tightly in a vessel which can afterwards be closed; set aside for three days; press strongly; reserve the liquid obtained; break up the marc; moisten it with one hundred and sixty millilitres of the Alcohol (20 per cent.); set aside for twenty-four hours; press strongly; add the liquid obtained to the portion previously reserved; break up the marc; mix it with the remainder of the Alcohol (20 per cent.); set aside for three hours; press again; evaporate the resulting liquid until it is reduced to such a volume that when added to the reserved liquid the whole measures four hundred and forty millilitres. Mix the evaporated liquid with the reserved liquid; heat the product in a covered vessel to 82° C. for a few minutes; set aside for twenty-four hours; filter, and pass Distilled Water through the filter until the filtrate measures four hundred and forty millilitres; add the Refined Sugar, and dissolve in a covered vessel by the aid of gentle heat; cool; add the Oil of Coriander dissolved in the Alcohol (90 per cent.); mix." *Br.*

The Br. preparation is much more concentrated than that of the U. S.

The process was improved in the U. S. P. VIII by simply adding the fluidextract and oil of coriander to syrup, and this process has been retained in the Ninth Revision.

Dose, of the U. S. syrup of senna, for an adult, from one to four fluidrachms (3.75–15.0 cc.); of the Br. syrup from one-half to two fluidrachms (2–7.5 cc.).

SYRUPUS TOLU. U. S. (Br.)

SYRUP OF TOLU Syr. Tolu [Syrupus Tolutanus U. S. P. IX]

Syrupus Tolutanus, *Br.;* Syrup of Balsam of Tolu; Sirop de Baume de Tolu, *Fr. Cod.;* Sirop balsamique, *Fr.;* Tolubalsamsirup, *G.,* Jarabe de balsamo de Tolu, *Sp.*

"Tincture of Tolu, 50 cc.; Magnesium Carbonate, 10 Gm.; Sucrose, 820 Gm.; Water, a sufficient quantity to make 1000 cc. Mix the tincture intimately with the magnesium carbonate and 60 Gm. of sucrose, in a mortar. Gradually add 430 cc. of water, with trituration, and filter. Dissolve the remainder of the sucrose in the clear filtrate with the aid of a gentle heat, strain the syrup while warm, and add sufficient water through the strainer to make the product measure 1000 cc. Syrup of Tolu may also be made in the following manner: Prepare a percolator as described under *Syrupus.* Pour the filtrate obtained as directed in the above formula upon the remainder of the sucrose contained in the percolator, return the first portions of the percolate until it runs through clear, and, when all of the liquid has passed, follow with water until the sucrose is dissolved and the product measures 1000 cc. Mix thoroughly.

"Alcohol content, by volume, 3.5 to 4.5 per cent." *U. S.*

"Balsam of Tolu, 25 *grammes;* Refined Sugar, 660 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Add four hundred grammes of the Distilled Water, boiling, to the Balsam of Tolu; cover lightly and heat on a water-bath for half an hour, stirring frequently. Remove; add Distilled Water, if necessary, so that the liquid, when cold, measures four hundred millilitres. Filter the solution, add the Refined Sugar, dissolve by the aid of a water-bath, and finally add sufficient Distilled Water to produce the required weight." *Br.*

The U. S. VIII process, which has been continued in the present revision, introduced magnesium carbonate with much advantage, and has the further improvement of using the official tincture of tolu instead of making the syrup from the balsam by a special process. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter.

Syrup of tolu is used chiefly to impart its agreeable flavor to mixtures. If a stronger preparation is desired, tincture of tolu may be added in the desired quantity, directing the bottle to be shaken.

Dose, one to four fluidrachms (3.75–15.0 cc.).

SYRUPUS URGINEÆ. Br.

SYRUP OF URGINEA

"Vinegar of Urginea, 175 *millilitres;* Refined Sugar, 650 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Mix the Vinegar of Urginea with an equal volume of Distilled Water. In the mixture dissolve the Refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." *Br.*

This syrup corresponds to the Syrup of Squill of the British Pharmacopœia and is used for the same purpose.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

SYRUPUS ZINGIBERIS. U. S., Br.

SYRUP OF GINGER Syr. Zingib.

Sirop de Gingembre, *Fr.;* Ingwersirup, *G.*

"Fluidextract of Ginger, 30 cc.; Alcohol, 20 cc.; Magnesium Carbonate, 10 Gm.; Sucrose, 820 Gm.; Water, a sufficient quantity to make 1000 cc. Mix the fluidextract and alcohol, and triturate the liquid in a mortar with the magnesium carbonate and 60 Gm. of the sucrose. Then gradually add 430 cc. of water with constant trituration, and filter. Dissolve the remainder of the sucrose in the clear filtrate, with the aid of a gentle heat, strain the syrup while warm, and, when cold, add enough water through the strainer to make the product measure 1000 cc.

"Syrup of Ginger may also be made in the following manner: Prepare a percolator as described under *Syrupus.* Pour the filtrate obtained as directed in the above formula upon the remainder of the sucrose, return the first portions of the percolate, and, when all of the liquid has passed, follow with water until the sucrose is dissolved and the product measures 1000 cc. Mix thoroughly.

"Alcohol content, by volume, 3.5 to 4.5 per cent." *U. S.*

"Ginger, in powder, 25 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Syrup, sufficient to produce 1000 *millilitres.* Prepare fifty millilitres of a strong tincture of the Ginger by the *process of percolation* with the Alcohol. To this add sufficient of the Syrup to produce the required volume." *Br.*

The U. S. P. process has been improved by the addition of magnesium carbonate as an aid in distributing the resinous fluidextract so as to facilitate its solution in water. It is practically a return to the U. S. 1870 method.

The British syrup, being made by the simple incorporation of an alcoholic tincture of the ginger with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavor. The old plan of using water as the menstruum for the drug has been abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavor particularly to carbonic acid water.

Dose, one to four fluidrachms (3.75–15.0 cc.).

TABELLÆ TRINITRINI. Br.

TRINITRIN TABLETS

Tablets of Nitroglycerin.

"Trinitrin Tablets are tablets of chocolate each weighing 0.300 gramme and containing 0.0005 gramme (0.5 milligram) of the trinitroglycerin of commerce. Each of these Tablets contains 0.5 milligram (approximately 1/130 grain) of the trinitroglycerin of comerce." *Br.*

A pill of nitroglycerin, made with althea and confection of rose, is recognized by the N. F. (see Part III). They afford a convenient mode of exhibiting glyceryl nitrate. The question of the stability of these tablets has frequently been brought up and many manufacturers have been penalized under the Food and Drug Act enforcement for supplying substandard tablets. Scoville (*J. I. E. C.,* 1915, 1054) states that nitroglycerin tablets containing less than 1/100 grain rapidly lose their strength on keeping, and suggests that this may be due to a finer attenuation of the nitroglycerin, thus favoring volatilization. As a second possible explanation the author calls attention to the two isomeric forms of nitroglycerin—a labile form melting at 2.8° C. and a stable form melting at 13.5° C. Nitroglycerin used in the paste form appears to be in a favorable condition owing to the presence of the solid matter and a trace of moisture, to forming the stable isomeride. Those tablets made from an alcoholic solution of nitroglycerin, appeared to be less stable than those made from the paste mixture. The subject was also investigated by a committee of the American Drug Manufacturers' Association in 1919 and the findings were to the effect that when the tablets are properly made there is no appreciable deterioration upon storage for a period of six months.

Dose, one to two tablets.

TALCUM PURIFICATUM. U. S.

PURIFIED TALC Talc. Purif.

"Purified talc is a purified native, hydrous magnesium silicate sometimes containing a small amount of aluminum silicate." *U. S.*

Talcum, *U. S. VIII;* Talc purifié, *Fr.;* Gereinigter Talc, *G.;* Talcum Venetum; Soapstone; Talc, *Fr. Cod.;* French Chalk; Creta Gallica; Talc de Venise, Craie de Briancon, *Fr.;* Talcum, *P. G.;* Talk, Talkstein, Speckstein, *G.*

Talc is a native acid metasilicate of magnesium (for account of other magnesium silicates, see Part II). It is found in various parts of the world; the largest producers being Vermont, New York and Virginia although considerable amounts are mined in other parts of the United States, in France, Austria and Italy (see Ladoo, *D. C.,* 1920, lxiv, 370). The finest quality is obtained in the Italian Alps. Talc is found in three forms, the foliaceous, fibrous and massive varieties. The latter occurs in irregular masses of a greenish-gray color, having a peculiar wax-like appearance of the surface, and giving when rubbed a greasy sensation to the skin. It is odorless, tasteless, and insoluble in water or in dilute solutions of the acids or alkaline hydroxides. Talc is largely used in the arts, especially in the manufacture of paper in which it is used as a filler.

When intended for medicinal or toilet uses the talc is first freed from limestone, marble or other similar impurities. It is then broken into small lumps and introduced into a disintegrator, where it is ground to a fine powder which is carried upwards into a vertical elevator pipe by means of a strong current of air, generated by a blower attached to the disintegrator. The most finely ground talc passes out of the top of the vertical pipe into a long canvas balloon and drops into a receiver below, as soon as the machinery stops. After adding perfume or desired medication the powdered talc if intended for toilet purposes is bolted through a fine sieve having 40,000 meshes to the square inch, being forced through by means of a rotating brush. For pharmaceutical uses it should not be in so fine a powder and requires to be purified by washing with hydrochloric acid. The present Pharmacopœia gives no process for its purification. That of the U. S. VIII was as follows:

"Talc, in fine powder, *five hundred grammes;* Hydrochloric Acid, *seventy-five cubic centimeters;* Water, *a sufficient quantity.* Mix the powdered Talc with about *twenty-five hundred cubic centimeters* of boiling Water, gradually add *fifty cubic centimeters* of the Hydrochloric Acid, and boil the mixture during fifteen minutes, then allow it to stand for fifteen minutes. Decant, and reject the supernatant liquid containing the finer particles of Talc in suspension, and again boil the residue with *twenty-five hundred cubic centimeters* of Water, mixed with the remainder of the Hydrochloric Acid, and allow it to stand for fifteen minutes. Again decant, and reject the finer suspended particles, and wash the coarser residue with Water by repeated decantation, until a portion of the wash-water, after filtering and acidifying with nitric acid, fails to become opalescent upon the addition of silver nitrate test solution. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it at 110° C." *U. S. VIII.*

Purified Talc is intended to replace magnesium carbonate, calcium phosphate, and other absorbent powders used to aid filtration, it having the advantage of insolubility, although its absorbent properties are deficient in comparison with magnesium carbonate. As much of the talc sold commercially has been bolted for use in toilet powders it is too fine for use as a filtering medium; the fine particles passing through the pores of the filter paper. For this reason the U. S. P. directs talc for filtering to be not finer than a No. 100 powder.

An interesting and valuable communication on the subject of filtering media is contributed to the *J. A. Ph. A.*, 1916, p. 506, by W. L. Scoville. In it he gives experimental data of the comparison of paper pulp, talc, infusorial earth and fuller's earth, in filtering aqueous solutions of alkaloids. He says that of the media experimented with, fuller's earth is the only one producing any marked change in the filtrate, and that it removes from 22 to 100 per cent. of alkaloidal substances from solution, depending upon the alkaloid and whether the liquid is acid, alkaline, or neutral. The "Mechanism of Filtration" is the title of an article by Hatchek (*J. S. C. I.*, 1908, p. 538), in which the effect of various filtering media is scientifically discussed and diagrammatically illustrated.

Description and Physical Properties.—"A very fine, white or grayish-white powder. It adheres readily to the skin. It is entirely free from grittiness and is unctuous to the touch.

"Mix 0.5 Gm. of Purified Talc with about 2 Gm. of anhydrous sodium carbonate and 2 Gm. of anhydrous potassium carbonate, heat the mixture in a platinum crucible until fusion is complete, the treat the resulting fused mass with hot distilled water. Then neutralize the liquid with diluted sulphuric acid, add another 10 cc. of the diluted acid, and evaporate the mixture until white fumes of sulphuric anhydride are evolved, and cool. Add 20 cc. of distilled water, boil the mixture, and filter. An insoluble residue of *silica* remains. The addition of ammonia T.S. and ammonium chloride T.S. to the filtrate may produce a white gelatinous precipitate of *aluminum hydroxide,* and the filtrate from this mixture on the addition of sodium phosphate T.S. yields a white, crystalline precipitate of magnesium ammonium phosphate.

"Purified Talc, when ignited at a red heat, loses not more than 5 per cent. of its weight. Boil 10 Gm. of Purified Talc with 50 cc. of distilled water for one-half hour, adding water from time to time to maintain approximately the original volume, and filter. The filtrate is neutral to litmus paper. One-half of this filtrate, when evaporated and dried at 110° C., yields not more than 0.005 Gm. of residue (*soluble substances*). The remaining half of this filtrate, after slightly acidulating with hydrochloric acid, does not yield a blue color upon the addition of potassium ferrocyanide T.S. (*iron*). Add 1 Gm. of Purified Talc to 20 cc. of diluted hydrochloric acid: no effervescence occurs (*carbonate*). Digest the mixture for fifteen minutes, and filter: a 10 cc. portion of the filtrate evaporated to dryness and ignited, leaves a residue weighing not more than 0.005 Gm. NOTE—Purified Talc is intended only as a filtering medium and for this purpose should not be finer than a No. 100 powder." *U. S.*

Uses.—Purified talc is used pharmaceutically (see above) and as a protecting, soothing powder to the skin. When in very fine powder it forms the basis of many of the proprietary toilet and infant powders, and is very valuable as a dusting powder in *intertrigo, prickly heat, pruritus,* and other conditions of dermal irritation.

Off. Prep.—Pulvis Talci Compositus, *N. F.*

TAMARINDUS. N. F., Br.

TAMARIND

"Tamarind is the partially dried ripe fruit of *Tamarindus indica* Linné (Fam. *Leguminosæ*), deprived of the brittle outer portion of the pericarp and preserved in sugar or syrup. Tamarind contains not more than 2 per cent. of foreign organic matter." *N. F.*

"Tamarinds are the fruits of Tamarindus indica, *Linn.*, freed from the brittle outer part of the pericarp and preserved with sugar." *Br.*

Fructus Tamarindorum; Tamarin, *Fr. Cod.;* Pulpa Tamarindorum cruda, *P. G.;* Tamarindemnus, Tamarinden, *G.;* Tamarindo, *It.;* Tamarindo (Pulpa de), *Sp.*

The tamarind, *Tamarindus indica* L., is the only known member of the genus *Tamarindus.* It is a large, spreading tree, attaining a height of 80 feet and with a trunk circumference up to 25 feet. It is indigenous to the upper Nile district of Africa and possibly southern Asia, and has been cultivated for centuries in tropical lands both for ornamental purposes and for its edible, acid fruits. The use of the latter as a laxative food was known to the ancient Hindus who imparted their knowledge concerning their properties to the Arabians. The Arabians introduced these fruits into Europe during the Middle Ages. At present, the tamarind is cultivated for the drug in India, West Indies and to a smaller extent in Florida. The tree possesses a brownish-gray, shaggy bark, alternate, paripinnate leaves with 20 to 40 oblong, opposite leaflets and pale yellow flowers arranged in lateral racemes. The fruit is a broad, compressed, reddish ash-colored pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in loculi formed by a tough membrane. Exterior to this membrane is a light-colored acid pulpy matter, between which and the shell are several somewhat branched tough ligneous strands, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated.

Calcutta appears to be the chief emporium for the tamarinds of the European markets. Tamarinds are also sent from Barbados and Antigua in the West Indies to England; when from this source they are preferred. The latter are known as West Indian tamarinds, and are obtained from *T. indica*, var. *occidentalis* Gärtn. They are of a light brown color, less cohesive and possess less acidity than the tamarinds from the Old World. Tamarinds are brought to us chiefly from the West Indies, where they are prepared by removing the epicarp, packing the decorticated fruits in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers. In India tamarinds are often prepared for market by stripping off the outer shell and pressing the pulpy interiors into a mass, with or without the addition of some salt as a preservative.

Properties.—Fresh tamarinds, which are sometimes brought to this country, have an agreeable, sour taste, without any mixture of sweetness. In the United States they are more usually met with in the preserved state; this is a dark-colored adhesive mass, consisting of syrup mixed with the pulp, membrane, and seeds of the pod, and having a sweet acidulous taste. The brown, flattish, quadrangular seeds, each enclosed in a tough membrane, should be hard, clean, and not swollen, the string-like fibers tough and entire, and the odor without mustiness.

Tamarind is officially described as "a pulpy mass of a light reddish brown color, changing with age to a dark brown, containing some branching fibers and numerous reddish brown, smooth, oblong or quadrangular, compressed seeds, each enclosed in a tough membrane; the pulp with parenchyma containing a few starch grains up to 0.020 mm. in diameter, calcium oxalate in rosettes up to 0.100 mm. in diameter, and crystal fibers with prisms of calcium oxalate up to 0.050 mm. in length. Odor distinct; taste sweet and agreeably acid." *N. F.*

"A reddish-brown, moist, sugary mass, containing strong branched fibres, and brown, shining seeds, each enclosed in a tough membrane. Taste agreeable, subacid. The pulp yields no characteristic *reactions* for copper." *Br.*

The Austrian Pharmacopœia excludes an article of a reddish-brown color. Some European Pharmacopœias limit the amount of seeds present and the Italian Pharmacopœia requires a minimum acid content.

K. Müller, after analyzing nine commercial varieties, gives the following figures for composition: Citric acid 4 to 6 per cent.; tartaric acid 5.3 to 8.8 per cent.; potassium bitartrate 4.7 to 6 per cent.; malic acid, traces only; insoluble matter 12 to 20 per cent.; seeds 1.5 to 38 per cent. (average 13.9). Copper may often be detected in preserved tamarinds, derived from the boilers in which they are prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a spatula or other steel implement immersed in the tamarinds.

Uses.—Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful when a laxative action is desirable. It is sometimes prescribed in connection with other mild cathartics. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power, and the same observation has been made of its influence upon the resinous cathartics in general. For a formula for *fluidextract of tamarind,* see *Nat. Drug.*, 1892, 101.

Dose, a drachm to an ounce (3.9–31 Gm.).

Off. Prep.—Confectio Sennæ, *Br., N. F.*

TARAXACUM. N. F. (Br.)

TARAXACUM Tarax. [Dandelion]

"Taraxacum consists of the dried rhizome and roots of *Leontodon Taraxacum* Linné (Fam. *Compositæ*). Taraxacum contains not more than 2 per cent. of foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

"Taraxacum Root is the fresh root of Taraxacum officinale, *Wiggers.* Collected in the autumn." *Br.*

Taraxaci Radix, *Br.;* Taraxacum Root; Dandelion Root; Blowball, Milk, Witch, or Yellow Gowan, Lion's-tooth, Cankerwort; Pissenlit, Dent de Lion, *Fr. Cod.;* Radix Taraxaci cum herba, *P. G.;* Löwenzahn, *G.;* Tarassaco, *It.;* Taraxacon, Diente de Leon, *Sp.*

The dandelion is a perennial herb native to Europe but now naturalized in many parts of the world, occurring almost ubiquitously in grassy places as a troublesome weed. Its subterranean portion consists of straight, fusiform root which in its upper part passes into an erect rhizome which sometimes branches into several secondary rhizomes. From the rhizome or its branches rosettes of coarsely pinnatifid leaves arise. These are usually runcinate, with the lobes toothed. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-colored flower, which closes in the evening and expands with the returning light of the sun. The involucre is smooth and double, with the outer scales bent downward. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is flat and naked. The pappus is stipitate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the achene attached. Another plant resembling the common dandelion, the achenes of which, however, are narrower and bright red or reddish brown, known as the *red-seeded dandelion,* is the product of *T. erythrospermum* Andrz., and is supposed by some to be naturalized from Europe. There seems little doubt but that the drug of commerce represents the rhizomes and roots of both of these species, as both often occur together and bear many features in common.

All parts of the plant contain a milky, bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and are much used as a food. The Pharmacopœias recognize only the root. It should be full grown when collected, and should be employed in the recent state. That most esteemed is collected during the months of July, August, and September. The commercial supplies of Taraxacum are imported from Germany, Holland and England.

Description and Physical Properties.—"*Unground Taraxacum.*—Cylindrical or somewhat flattened, gradually tapering, usually in broken pieces, from 6 to 15 cm. in length and from 5 to 15 mm. in thickness; externally brown or blackish brown, longitudinally wrinkled, having numerous root and rootlet-scars; crown simple or branched with numerous leaf-bases showing annulate markings; fracture horny, short, non-fibrous. Odor slight or inodorous; taste bitter.

"*Structure.*—A porous, pale yellow, non-radiate wood from 1 to 4 mm. in diameter, surrounded by a light brown bark from 2 to 6 mm. in thickness, the latter containing concentric layers of laticiferous vessels and sieve tissues, alternating with whitish inulin-bearing parenchyma. The rhizome portions show a small pith.

"*Powdered Taraxacum.*—Light brown; parenchyma cells, large, thin-walled and containing irregular masses of inulin; fragments with yellowish brown laticiferous vessels; tracheæ reticulate; intermediate fibers non-lignified, with irregular, simple and oblique pores; starch wanting.

"Preserve Taraxacum in tightly closed containers." *N. F.*

"Fresh root frequently three decimetres or more long, and twelve millimetres or more thick, smooth and yellowish-brown externally, whitish within. Fracture short, the exposed surface showing a small yellow porous wood, surrounded by a thick nearly white cortex exhibiting a variable number of irregular concentric rings, from which a milky juice exudes. Inodorous; taste bitter." *Br.*

The roots of various plants have been largely substituted for dandelion in England and on the Continent by the herb gatherers, and we are informed that fraudulent substitution is not infrequent, in this country, of the root of *Cichorium Intybus* L., or *chicory.* It is rare to find chicory mixed with dandelion, the former being usually boldly substituted for the latter. Chicory rhizomes or roots are readily detected, upon fracture, by their radially arranged laticiferous vessels in the bark region. In dandelion these are arranged in concentric circles.

In 1839 Polex isolated a bitter crystalline principle which he called *taraxacin* and later Kromayer (1861) a second crystalline substance which he called *taraxacerin,* but F. B. Power (*C. D.,* 1912, p. 822) states that both of these substances are indefinite mixtures. The root contains in the fall about 25 per cent. of inulin but the quantity in the spring is considerably less; also about 17 per cent. of uncrystallizable sugar and a soluble carbohydrate called *levulin,* $C_6H_{10}O_5$. According to Vogel, the intra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. L. E. Sayre found that the yield of taraxacin varies in roots collected at different seasons. (See *Proc. A. Ph. A.,* 1893, 1894, 1895, 1896, 1897.) Power found in the air dried English root, an enzyme, essential oil, oily resin, fatty acids, including *melissic,* and *p-hydroxy-phenylacetic acid,* which had never before been isolated from a plant.

Uses.—Taraxacum was formerly supposed to possess cholagogic as well as diuretic powers. It has been used in various conditions accompanied with congested or *torpid liver.* There is, however, no sufficient reason for believing it possesses any therapeutic virtues. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is roasted and powdered and then prepared in the same manner.

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Fluidextractum Taraxaci, *N. F.* (*Br.*); Extractum Taraxaci, *N. F., Br.;* Succus Taraxaci, *Br.;* Elixir Gentianæ Glycerinatum, *N. F.;* Elixir Taraxaci Compositum, *N. F.;* Elixir Eriodictyi Aromaticum, *N. F.;* Elixir Guaranæ, *N. F.*

TEREBENUM. U. S., Br.

TEREBENE Tereben.

"Terebene is a mixture of terpene hydrocarbons, chiefly dipentene and terpinene, obtained from oil of turpentine." *U. S.* "Terebene is a mixture of dipentene and other hydrocarbons, obtained by shaking oil of turpentine with successive quantities of sulphuric acid until optically inactive, and then distilling in a current of steam." *Br.*

Térébène, *Fr.;* Tereben, *G.*

This substance is produced by the action of sulphuric acid upon oil of turpentine. The sulphuric acid must be added gradually to the cooled oil of turpentine, in the proportion of one part of acid to twenty parts of oil, and after a day's standing the mixture is heated to boiling. After cooling, the oily layer is removed, freed from acid by calcium carbonate, and rectified. Some cymol is always produced at the same time, and by continued action of the acid the terebene is said to be entirely converted into cymol and colophene. Jayne and Chase (*A. J. P.*, 1887, p. 65) found an inactive camphor, boiling at about 200° C. (probably borneol), to be formed also, and the residue left on rectifying was principally *colophene.*

Description and Physical Properties.—"A colorless, thin liquid. It has a rather agreeable, thyme-like odor, and a somewhat terebinthinate taste. On exposure to light and air, Terebene gradually becomes resinified and acquires an acid reaction. It is practically insoluble in water, but miscible with chloroform, ether, and dehydrated alcohol. One cc. is soluble in 3 cc. of alcohol at 25° C.

"Specific gravity: 0.860 to 0.865 at 25° C. It boils between 160° and 172° C. Terebene does not redden blue litmus paper which has been moistened with alcohol. Its optical rotation does not exceed $+0.3°$ in a 100 mm. tube at 25° C. (*unaltered oil of turpentine*). After the determination of the boiling point, transfer the residue remaining in the distilling flask to a dish, by means of ether, and evaporate the liquid on a water bath: the residue remaining does not exceed 1 per cent. of the original weight of Terebene taken (*rosin*).

"Preserve in well-closed containers, protected from light." *U. S.*

"A colorless liquid. Agreeable odor; taste aromatic and terebinthinate. Specific gravity from 0.862 to 0.866. Soluble in 5 parts of *alcohol* (90 per cent.). *Optical rotation* at 15.5° C., $+1°$ to $-1°$. Distils between 156° and 180° C., leaving only a slight viscous residue (absence of excess of resin). Not more than 15 per cent. distils below 165° C." *Br.*

Power and Kleber (*Ph. Rund.*, 1894, 18) stated that pinene is not obtained by the action of sulphuric acid on oil of turpentine, that the boiling points 156° to 160° C. should be 170° to 185° C., and that the sp. gr. should be 0.855 instead of 0.862; also that terebene consists mainly of dipentene and terpinene with some cymol and camphene.

Uses.—Terebene is a valuable stimulant expectorant, first recommended by William Murrell (*B. M. J.*, Dec., 1885), in that form of *chronic bronchitis* often known as *winter cough.* It is very useful not only in cases of chronic bronchitis, but also in the *acute* disease, after the earlier stages have passed by. It probably exerts upon other mucous membranes the same action that it does upon that of the lungs, and it has been employed with asserted good results in *dyspepsia,* especially in the flatulent intestinal variety, and may be used in chronic or subacute inflammation of the genito-urinary tract. Its action upon the general system has not been investigated, but probably resembles that of oil of turpentine. It may be given in emulsion, or by dropping into half a teaspoonful of sugar. It is also sometimes administered in pastils or lozenges. It has been used by atomization, with asserted good results. Murrell (*B. M. J.*, July 24, 1884) states that terebene is an active antiseptic and germicide, one part in four hundred and fifty being able to keep in check the action of the yeast plant, and one part in five hundred having a very perceptible influence on the development of bacilli and paramœcia.

Dose, two to eight minims (0.12–0.5 cc.).

TEREBINTHINA. N. F.

TURPENTINE Terebinth.

"Turpentine is a concrete oleoresin obtained from *Pinus Palustris* Miller and from other species of *Pinus* (Fam. *Pinaceæ*). Turpentine contains not more than 2 per cent. of foreign matter." *N. F.*

White Turpentine; Thus Americanum; Common Frankincense; Terebinthina Communis; Terebinthina Pini, *Fr. Cod.;* Térébinthine du Pin, Térébinthine Commune, *Fr.;* Fliessharz, Terpentin, *G.;* Tremntina commune, *It.;* Trementino de Pino, *Sp.*

The word "turpentine" properly refers to the mixture of resin and volatile oil—whether liquid or concrete—which is obtained from coniferous trees. The word is sometimes, however, given a larger meaning and applied to similar oleoresins from other botanical families; in France it is applied to any oleoresin which does not contain benzoic or cinnamic acid.

The oleoresins from various species of pine trees have been used in the arts and in medicine from time immemorial in various parts of the world. They were collected from those species which were most abundant in each section. As a result there have been recognized a large number of turpentines which differ considerably among themselves both in their chemical and physical properties. At present the bulk of the world's supply of turpentine comes from America. Of the numerous varieties of turpentine we shall describe briefly, in addition to the official, those which are of medicinal importance.

The official turpentine is derived chiefly from the *Pinus palustris* and the *P. Tæda.* It occurs in the sap wood and is obtained by making incisions through the bark and wood and collecting the exudation in cavities or boxes made lower down on the trunk, from which it is dipped into barrels or other receptacles.

Pinus palustris Mill. (*P. australis* Michx. *f.*).—The names by which the tree is known in the Southern States are *long-leaved pine, yellow pine, Southern pine, hard pine, Virginia* *pine,* and *pitch pine;* but the first is the most appropriate. The leaves occur three in a group, being from ten to fifteen inches long, subtended at the base by a conspicuous scaly sheath from one to one and a half inches long and crowded at the ends of the branches. The cones are terminal, conical, and armed with a short recurved spine. This pine is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. It grows to a height of sixty or seventy feet, and the diameter of its trunk is about fifteen or eighteen inches for two-thirds of its height. This tree furnishes by far the greater proportion of the turpentine, tar, etc., consumed in, or exported from, the United States. (See *Pix Liquida.*)

Pinus Tæda L.—This is the *loblolly* or *old field pine* of the Southern States. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are about six inches long, and of a light green color. It yields turpentine in abundance, but the quantity is less than that which flows from the preceding species.

Pinus Sabiniana Dougl., known as *nut-pine* or *digger-pine* (because the nut is largely consumed by the Digger Indians), yields, on being notched, a turpentine whose volatile oil is extensively used in California under the name of *abietene.* The *Pinus rigida,* or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar. *Pinus Teocoty* Cham. et Schlecht. yields a turpentine known as *Mexican* or *Brea turpentine,* which is used in Mexico.

A substance resembling manna, of a sweet, slightly bitter and terebinthinate taste, and actively purgative, exudes from incisions in *Pinus lambertiana,* of Oregon, and was used by the natives. Berthelot extracted from this product a principle, *pinite.* It is very sweet, but does not undergo the vinous fermentation. Pinite was for a long time classed among the sugars, but the latest researches seem to show that it is a hexahydric phenol derived from hexahydrobenzene. (*J. Am. C. S.,* 1891, xiii, 228.) The formula is $C_{17}H_{14}O_6$, and it is a methyl derivative of inosite. It is sometimes called *American Manna.*

Collection.—In former times, large quantities of turpentine were collected in New England, but the turpentine trees of that section have long been entirely exhausted, and our commerce has been until recently almost exclusively supplied from North Carolina and the southeastern parts of Virginia. Latterly attention was turned to the collection of this valuable product of Georgia and Florida, and now an abundant supply is derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico.

During the winter, deep notches or excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground, and for about three feet above these so-called "boxes" the tree is deprived of its bark and some of the wood scraped off. Into these the turpentine or "crude" begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumn, the tree being scraped every eight or ten days to prevent clogging. The liquid is removed from the "boxes" as they fill, and transferred into casks, where, if left, it gradually thickens, and ultimately acquires a soft solid consistence, but most of it is separated at once by distillation into the rosin and the volatile oil of turpentine.

When a tree is boxed, it is weakened and falls easily before the wind. To obviate the former destructive method, Herty has devised "the cup and gutter system." (See *Bulletin No. 40, Bureau of Forestry;* also *A. J. P.,* 1916, lxxxviii, 191.) By this method a small incision is made through the bark and a strip of galvanized iron is inserted. The turpentine flows along this strip and is caught in an earthenware receptacle much resembling a medium-sized flower pot inserted upon the tree. This method increases the yield of turpentine and has been adopted by some of the producers. E. S. Oliver (*National Drug.,* 1920, l, 394) describes a process which he claims gives double the output without injury to the trees. Large quantities of turpentine are now prepared directly from the stumps, roots, sawdust and wood of the trees which were wasted by the older or box method of collecting the oleoresin. "Wood" turpentine is not recognized as equivalent to "turpentine" by the Pure Food and Drugs Act, and must be labelled as "Wood Turpentine." The latter has a peculiar odor and is not used in medicine but is widely used in the arts. Wood turpentine is also produced as a by-product in the manufacture of sulphite cellulose.

Turpentine is likely to contain small pieces of bark, wood, or other impurity.

Composition.—Turpentine is a mixture of volatile oil and resin. In the recent state the proportion of volatile oil is about 7 per cent. but is less in old samples as the oil gradually oxidizes into resin.

Tschirch and Koritschoner (*A. Pharm.,* 1902) found the following constituents in white turpentine: *palabiennic acid,* $C_{13}H_{20}O_2$, 5 per cent.; *palabietinic acid,* $C_{20}H_{30}O_2$, which is crystalline, 6 to 7 per cent.; *α-* and *β-palabietinolic acids,* together 53 to 57 per cent. Both the latter are amorphous and are separated by the differing solubility of their lead salts. All the acids are soluble in sodium hydroxide solution. The portion of the resin insoluble in NaOH solution consists of essential oil, 20 to 22 per cent., and *paloresene,* 10 per cent., with traces of a bitter principle. The essential oil is dextrogyrate, while the resin itself and palabietinic acid are lævogyrate.

Properties.—The turpentines resemble one another in odor and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, called *oil of turpentine,* the composition of which is essentially uniform, it being composed of several terpenes (pinene, dipentene, and sylvestrene) of the formula $C_{10}H_{16}$, the residue consisting exclusively of rosin. (See *Oleum Terebinthinæ* and *Resina.*)

White turpentine, as found in commerce, is yellowish white, of a peculiar somewhat aromatic odor, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer it is almost semi-fluid and very adhesive; though brittle in the winter it is often so firm and hard as to be incapable of being made into pills without heat.

Description and Physical Properties.—"Turpentine occurs in yellowish, opaque masses, lighter internally, sticky and more or less glossy, brittle in the cold. Odor and taste characteristic.

"It is freely soluble in alcohol, ether, chloroform, or glacial acetic acid. Its alcoholic solution is acid to litmus. Dissolve about 1 Gm. of Turpentine, accurately weighed, in 25 cc. of alcohol and collect the insoluble residue, if any, on a filter which has been dried at 100° C. and weighed. Wash the residue and filter with about 25 cc. of alcohol and dry at 100° C. The weight of the residue does not exceed 2 per cent. (*mechanical impurities*)." *N. F.*

Schiff affirms that the odor of turpentine is due to the presence of a product of oxidation, probably a camphoric aldehyde, $C_{10}H_{16}O_3$, which, with the odor, may be removed by shaking the turpentine with sodium bisulphite. A non-odorless turpentine may also be obtained by washing with solution of sodium hydroxide and distilling in an atmosphere of carbon dioxide. From the experiments of Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Méd.,* 1830, 94.) According to Thierry, the same result is obtained by the addition of calcium hydroxide. (*J. P. C.,* 3e sér., i, 315.)

Ed. Hirschsohn made experiments with the object of determining a reliable method for distinguishing artificial turpentine from the common, natural turpentine and larch turpentine; this becomes possible by the difference in the solvent effect of official ammonia water and alcohol, sp. gr. 0.863 at 15.6° C., upon them, under the conditions indicated in the following table:

Kind of Turpentine.	Ammonia Solution (sp. gr. 0.960), 1 p. turpentine and 5 p. ammonia solution.	Alcohol (sp. gr. 0.863), 1 p. turpentine and 3 p. alcohol.
Venice turpentine	Is not disintegrated; produces a milky fluid in the water bath.	Yields a nearly clear solution.
Common turpentine	Easily disintegrated, forming a milky mixture, then gelatinous, becomes clear in the water bath.	Large quantities are deposited, but the mixture becomes clear in the water bath.
Artificial turpentine	Is disintegrated, becomes clear in the water bath for a moment, then turbid.	Turbid solution and precipitation; turbid in the water bath with precipitation.

A mixture of common turpentine with larch (Venice) turpentine is recognized by the turbidity of, and precipitate from, the solution of 1 Gm. of the sample in 3 Gm. of alcohol sp. gr. 0.863. The same occurs if the common is replaced by artificial turpentine, but the latter is differentiated by ammonia, from the fact that in the presence of 20 to 30 per cent. of common turpentine the sample is easily disintegrated, and the solution becomes clear in the water bath, while in the presence of artificial turpentine the behavior is the same as with the pure Venice turpentine. (*Ph. Centralh.,* Nov. 26, 1903, 825 to 828.)

UNOFFICIAL TURPENTINES

European turpentine—the *Terebinthina vulgaris* of the old London Pharmacopœia—is furnished chiefly by *P. sylvestris* L. (*Scotch Pine, Norway Pine*) and *P. Pinaster* Soland. From the latter tree it is obtained largely in the maritime districts of the southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine.* The substance which the French call *galipot,* or *barras,* is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch,* and is sometimes substituted for *Burgundy pitch.* (See Part II.) European turpentine is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like that of thickened honey. As found in European commerce, it often consists wholly of this latter portion. It speedily hardens on exposure in thin layers to the air. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two parts of the turpentine (*J. P. C.*, xxv, 499.) Tschirch and Bruening (*A. Pharm.*, 1900, ccxxxvii, 630) find this oleoresin to have the following composition: 6 to 7 per cent. of *pimarinic acid,* $C_{14}H_{22}O_2$; 8 to 10 per cent. of *pimaric acid,* $C_{20}H_{30}O_2$; 48 to 50 per cent. of *alpha-* and *beta-pimarobic acids,* $C_{18}H_{26}O_2$; 5 to 6 per cent. of *bordoresin,* together with traces of *succinic acid.* The acid resins are soluble in sodium hydroxide solution, the pimarinic acid being separable from the other two by its property of forming with ammonium carbonate a water-soluble double salt. The volatile oil consists of two fractions, the larger fraction, amounting to about 85 per cent. of the whole, distilling easily. It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and rosin. We do not import it into this country.

Venice Turpentine (*Larch Turpentine*).—The N. F. formerly recognized under the title of *Terebinthina Laricis* "the viscid oleoresin obtained from *Larix europœa* De Candolle (Fam. *Pinaceæ*)." *N. F.*

The genus *Larix* differs from all the other coniferous trees in that its leaves are deciduous. The European Larch (*Larix decidua* Mill., *L. europœa* DC.), from which this oleoresin is obtained, is a large tree found especially in the mountainous regions of Europe and Siberia. The leaves are narrowly linear, about one inch in length, in fascicles on short scaly branches and the cones ovoid and a little longer than the leaves. It yields, besides the *Venice turpentine* of commerce, a peculiar sweetish substance called in France *Briancon manna* which exudes spontaneously and concretes upon the bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes and is called *Orenburg gum.* It is wholly soluble in water.

The oleoresin is collected in France and southern Tyrol during the spring by boring holes into the wood of the trees and plugging. The plugs are later removed and the oleoresin collected in suitable containers. The commercial supplies are chiefly imported from France and Italy.

Venice turpentine was described by the N. F. IV as "a nearly transparent yellowish or yellowish green, thick liquid heavier than water, and having a distinctive odor and a bitter characteristic taste. Completely soluble in alcohol, glacial acetic acid, acetone or chloroform. Almost entirely soluble in petroleum benzin with the separation of a light flocculent deposit. One part of Venice turpentine dissolves completely and forms a clear solution in 3 parts of 80 per cent. alcohol. It may possess a slight, greenish fluorescence when viewed by reflected light but exhibits no violet or purple fluorescence (*rosin oil*). Dissolve 5 Gm. of Venice turpentine in 25 cc. of alcohol, add a few drops of phenolphthalein T.S. and render the solution slightly alkaline by the addition of a 10 per cent. solution of potassium hydroxide. The resulting solution is clear and transparent and no separation of oily drops occurs (*rosin oil*). Its acid number is not more than 80 when determined as directed in the U. S. Pharmacopœia IX." *Pinaceæ*)." *N. F. IV.*

It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. H. Beckurts and W. Brueche found the specific gravity at 15° C. from 1.060 to 1.190; acid number from 76 to 101 (Kremel found from 68 to 70.3); ester number from nothing to 6; saponification number from 81 to 101, and the iodine number from 137 to 149. (*A. Pharm.*, 1892, ccxxx, 83.) It yields on an average 15 per cent. of essential oil, which has been found to be nearly pure *pinene.* The residual resin is soluble in two parts of warm alcohol of 57 per cent., and more copiously in absolute alcohol.

Tschirch and Wiegel (*A. Pharm.*, 1900, pp. 401, 487) found in larch turpentine from 60 to 64 per cent. of acid resins soluble in soda, from 20 to 22 per cent. of volatile oil, and from 14 to 15 per cent. of indifferent resin. The acid resins consist mainly of two isomeric amorphous bodies, *a*- and *b*-larinolic acid, $C_{18}H_{26}O_2$, and a smaller quantity of the crystalline *laricinolic acid,* $C_{20}H_{30}O_2$. The greater portion of the volatile oil boils between 155° and 170° C.; a smaller quantity of higher boiling sesquiterpene commencing to boil at 190° C. The recently distilled oil has the sp. gr. 0.872, and possesses a characteristic turpentine odor. It is soluble in all proportions in alcohol and other solvents.

What is sold under the name of Venice turpentine, in commerce, is usually quite brown, and is a factitious substance prepared by dissolving rosin in oil of turpentine. According to G. Fabris the nature of these spurious Venice turpentines can readily be detected by dissolving 5 Gm. of the sample in 20 cc. of 95 per cent. alcohol, adding a few drops of phenolphthalein and sufficient of a 10 per cent. solution of potassium hydroxide to render it alkaline. With genuine Venetian turpentine a clear solution is obtained, while the spurious drug yields a turbid solution from which on standing, drops of oily resin separate.

Finnan Turpentine, the oleoresin of *Pinus sylvestris,* is found by Tschirch and Niederstadt to consist of: 1.5 per cent. *silveolic acid,* $C_{14}H_{20}O_2$; 58 to 60 per cent. of *a-silvinolic acid,* $C_{15}H_{26}O_2$, and *β-silvinolic acid* ($C_{14}H_{24}O_2$); 20 to 21 per cent. of *resene;* 15 per cent. of volatile oil; and traces of bitter principle and succinic acid. Silveolic acid is crystalline; α- and β-silvinolic acids are both amorphous. The volatile oil has the sp. gr. 0.840 at 15° C., is soluble in all proportions in alcohol, ether, and chloroform, and is neutral when recently distilled, but becomes acid when exposed to the air. (*A. Pharm.*, 1901, ccxxxix, 167.)

Jura Turpentine.—A. Tschirch and E. Bruening have determined the following constituents of the oleoresin of *Picea vulgaris:* From 2 to 3 per cent. of *picea-pimarinic acid,* $C_{18}H_{20}O_2$; from 1.5 to 2 per cent. of *picea-pimaric acid,* $C_{20}H_{30}O_2$; from 48 to 50 per cent. of α- and *β-picea-pimarolic acid,* $C_{25}H_{44}O_2$; from 32 to 33 per cent. of volatile oil; from 10 to 12 per cent. of resene, $C_{21}H_{36}O$; and traces of succinic acid, coloring matter and bitter principle. (*A. Pharm.,* 1900, ccxxxviii, 616.)

Tschirch and Weigel (*A. Pharm.,* 1900, 401, 487) investigated *Strassburg turpentine*—the oleoresin of *Abies Picea;* it contains from 8 to 10 per cent. of an acid resin, *abietinic acid,* $C_{13}H_{20}O_2$; from 1.5 to 2 per cent. of a crystalline acid resin, *abietolic acid,* $C_{20}H_{28}O_2$; from 46 to 50 per cent. of two amorphous isomeric acid resins, α- and *β-abietinolic acid,* $C_{16}H_{24}O_2$; from 12 to 16 per cent. of a neutral resin, *abieto-resin;* and from 28 to 30 per cent. of volatile oil, together with traces of succinic acid, bitter principle, coloring matter, moisture and impurities. The oil when recently distilled has the sp. gr. 0.860, boiling between 148° and 165° C.; the major fraction distils between 162° and 163° C. It has a greenish fluorescence and a lemon-like odor. When the oleoresin is distilled with potassium hydroxide a pleasant rose or orange-flower odor is developed, possibly due to the liberation of a fragrant alcohol.

In Japan, the exudation from the *Pinus densiflora* Sieb. et Zucc., and that from the *Pinus Thunbergii* Parl. are used under the respective names of *akamatsu* and *kuromatsu.* They are said to contain about 18 per cent. of oil and 81 per cent. of resin. The distilled oil is bright and colorless, having an odor somewhat different from that of the European oil of turpentine. It boils at from 155° to 156° C., and has a specific gravity of a little under 0.87. Its index of polarization is from 55° to 61° (dextrogyrate). The resin cannot be distinguished from the European.

Uses.—The physiological activities of the turpentines depend upon their volatile oils (see *Oleum Terebinthinæ*). They are so inconvenient of administration and so variable in their activity that at present they are almost never used internally. They are occasionally used externally for their local irritant effects, but even for this are inferior to corresponding dilutions of the volatile oil. Solid turpentines are used like resin sometimes to stiffen ointments where a stimulating effect is not undesirable.

TEREBINTHINA CANADENSIS. Br.

CANADA TURPENTINE

"Canada Turpentine is the oleo-resin obtained from Abies balsamea, *Mill.*" *Br.*

Canada Balsam, Balsam of Fir; Balsamum Canadense; Baume du Canada, *Fr. Cod.;* Térébenthine du Canada, *Fr.;* Canadischer Terpentin, *G.;* Canadischer Balsam, Canadischer Terpentin, *G.;* Trementina del Canada, *It.*

Terebinthina Canadensis, Br., is collected in Canada and the State of Maine from the *Abies balsamea,* by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle.

Abies balsamea (L.) Mill., (*A. balsamifera* Michaux).—This is the *American silver fir,* or *balm of Gilead tree* or *Fir Balsam* inhabiting Canada, Nova Scotia, Maine, and the mountainous regions farther south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height and form an almost perfect cone. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish color, and covered with a resinous exudation, which gives them a glossy, rich, and beautiful appearance.

Several other species of Abies are important. The *A. Picea* Lindl. (*Abies pectinata* of De Candolle, *Pinus picea* of Linnæus), or *European silver fir,* growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strassburg turpentine* (*Térébenthine d'Alsace* or *des Vosges*), which is much used in some parts of Europe. By the distillation of its cones with water it also affords a variety of oil of turpentine called in France *essence de templine.* By boiling the young branches of the allied *Picea Mariana* (Mill.), B. S. P. (*Pinus nigra* Link.), or *black* or *bog spruce* of this country, and evaporating the decoction, the *essence of spruce* is prepared. It is a thick, molasses-like liquid, with a bitterish, acidulous, astringent taste, and is used for making *spruce beer.* (See *U. S. D.,* 19th edition, page 1244.)

Abies Fraseri Lindley, commonly called *double fir* and *she-balsam* occurs at high elevations in the mountains of Tennessee and North Carolina. The tree is noted for its hardiness, and is used for ornamental purposes. It is also said to have been used to furnish a balsam of fir similar to that obtained from *A. balsamea,* but the data concerning this are obscure.

Abies Douglasii Lind. (*Pseudotsuga Taxifolia* Brit.).—From this a *Balsam of Fir* of the Pacific Slope has been obtained; it is a turpentine similar to Canada balsam and is extensively sold under the names *Oregon Balsam* or Oregon Balsam of Fir. Roberts and Becker (*Proc. P. P. A.,* 1913, p. 328) state that Canada balsam is thicker than Oregon balsam, dries to a solid, transparent film, while Oregon balsam remains sticky, has a lower acid value than Oregon balsam, and solidifies when mixed with 20 per cent. of magnesium oxide, which Oregon balsam does not.

Russian White Pitch, "Belji var," "Sos nowaja Smold," which is probably derived from the Siberian Fir, *Abies Pichta* Forb. (*Picea obovata* Ledeb.), contains, according to A. Tschirch, two free resin acids, the amorphous, *beljiabiennic acid,* $C_{13}H_{20}O_2$, and the crystalline, *beljiabietinic acid* besides *beljiresene,* $C_{13}H_{36}O$ and an essential oil. (*A. Pharm.,* Nov., 1902.)

Properties.—Canada turpentine is "pale yellow or greenish-yellow, transparent, viscous. Agreeable terebinthinate odor; taste feebly bitter and acrid. Dries very slowly to a transparent varnish when exposed to the air. Solidifies when mixed with about one-sixth of its weight of *heavy magnesia* moistened with a little *water.*" *Br.*

"It is completely soluble in ether, chloroform, or benzene." *U. S. VIII.*

For a paper on its miscibility in alcohol, by J. E. Morrison, see *Proc. A. Ph. A.,* 1894, 309. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles under the name of *Canada balsam* or *balsam of fir.* Under the microscope the hard balsam is found to be entirely free from any granular or crystalline structure. In Europe it is sometimes called *balm of Gilead,* from its supposed resemblance to that celebrated medicine. The term *balsam,* as at present understood, is improperly applied to it, as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine 18.6 parts of volatile oil, 40.0 of resin easily dissolved by alcohol, 33.4 of sub-resin of difficult solubility in that fluid, 4.0 of caoutchouc similar to sub-resin, and 4.9 of bitter extractive and salts, besides traces of acetic acid. Flückiger found in 100 parts, 24 parts of an essential oil, $C_{10}H_{16}$, with a very small proportion of an oxygenated oil, 60 parts of a resin soluble in boiling alcohol, and 16 parts of a resin soluble only in ether. (*Pharmacographia,* 2d ed., 614.) Emmerich obtained by fractional distillation of the oil, *bornyl* or *terpinyl acetate, pinene,* and a fragrant liquid resembling oil of lemon. (*A. J. P.,* 1895, 135. See also a paper by Hunkel, *A. J. P.,* 1895, 9.) The chief distinction between it and *Strassburg turpentine,* which is sometimes sold for it in commerce, is in the odor.

According to Tschirch, Wiegel and Bruening, Canada turpentine contains about 63 per cent. of acid resins, from 23 to 24 per cent. of volatile oil, and from 11 to 12 per cent. of indifferent resin. The acid portion consists of four acids, of which one—*canadinic acid,* $C_{19}H_{34}O_2$—is obtained by treating the oleoresin with ammonium carbonate, with which it combines; a small amount of crystalline *canadolic acid,* $C_{19}H_{28}O_2$, and two amorphous isomeric acids — *a-* and *β-canadinolic acids,* $C_{19}H_{30}O_2$—which constitute the main portion of the acid resins. The indifferent resin has the formula $C_{21}H_{40}O$. The greater part of the volatile oil boils between 160° and 167° C. (*A. Pharm.,* 1900, Aug. and Sept., 401, 411 and 487.)

Uses.—The medicinal properties of this resembles that of the other turpentines. It is little used as a therapeutic agent by the medical profession although it is a popular folk remedy in the regions it inhabits being used as a vulnerary and internally for coughs. It is largely employed as a cement for glassware and as a permanent mounting medium for histological specimens.

TERPINI HYDRAS. U. S.

TERPIN HYDRATE Terpin Hyd.

"A dihydric alcohol [$C_{10}H_{18}(OH)_2.H_2O$]." *U. S.*

Terpinum, *Fr. Cod.;* Dihydrate de Térébenthène, Hydrate de Terpilène, *Fr.;* Terpinum Hydratum, *P. G.;* Terpinhydrat, *G.;* Terpina, *Sp.*

In making terpin hydrate a mixture of four parts of rectified oil of turpentine, three parts of alcohol (sp. gr. 0.863), and one part of nitric acid is put in large, shallow porcelain dishes and allowed to stand for three or four days. The crystals which have formed are then collected and allowed to drain thoroughly; they are then pressed between sheets of absorbent paper, and crystallized from a cold solution in 95 per cent. of alcohol. The product is about 12 per cent. of the original turpentine oil. E. T. Hahn proposed the use of methyl alcohol (sp. gr. 0.801) in place of alcohol, in making terpin hydrate. (*A. J. P.,* 1897, 73.) L. Krentmann states that good results are obtained by replacing the alcohol in the process with hydrogen dioxide solution and subjecting the mixture poured into shallow dishes to light and air. The temperature should be carefully regulated so that the range will be between 15° and 20° C.

The anhydrous *terpin* $C_{10}H_{18}(OH)_2$, obtained from it by the loss of water, has the characters of a glycol. Dipentene dihydrochloride is its hydrochloric acid ether. By the loss of water the terpin then becomes *terpineol,* $C_{10}H_{17}(OH)$, a liquid with an aromatic odor resembling lilac, and finally yields dipentene, terpinene, or terpinolene, according to the conditions of its treatment. Bouchardat and Voiry obtained terpineol in crystals which melt at 35° C. and remain in superfusion for long periods. (*Ann. Ch. Ph.,* 1893, 103.) For Wallach's researches on crystallized terpineol, see *P. J.,* 1893, 2.

The yield of crystallizable material is largely dependent upon the temperature at which the reaction is allowed to proceed. If the temperature be too high, polymerization of the turpentine takes place; if too low, the yield is insufficient.

Properties.—"Colorless, lustrous crystals, or a white powder. It has a slight odor, and is efflorescent in dry air. One Gm. of Terpin Hydrate is soluble in about 200 cc. of water, 13 cc. of alcohol, 135 cc. of chloroform, and in 140 cc. of ether, at 25° C. One Gm. is soluble in about 34 cc. of boiling water, in 3 cc. of boiling alcohol, and in about 1 cc. of boiling glacial acetic acid. When slowly heated to about 100° C., Terpin Hydrate sublimes in fine needles. It loses its water of crystallization at 100° C. It is also slowly dehydrated by drying over sulphuric acid.

"Preserve in well-closed containers, in a cool place.

"When quickly heated, Terpin Hydrate melts between 115° and 117° C. with the loss of water. Add a few drops of sulphuric acid to a hot aqueous solution of Terpin Hydrate: the liquid becomes turbid and develops a strongly aromatic odor.

"Terpin Hydrate has no odor of turpentine, and its hot aqueous solution (1 in 100) is not acid to litmus paper. Ash: not more than 0.05 per cent." *U. S.*

The pharmacy of terpin hydrate seems to be much misunderstood if one may judge by the liquid preparations on the market purporting to contain amounts of terpin hydrate impossible to be held in solution by the alcoholic strength of the preparation. It requires about 40 per cent. of alcohol in the finished preparation to hold in solution an amount of terpin hydrate corresponding to one grain to each fluidrachm.

Uses.—Terpin was first physiologically investigated by Lépine, in 1855, who found it to act both upon the mucous membranes and upon the nervous system in a manner similar to the oil of turpentine. It has since been used in *chronic bronchitis* and in the advanced stages of *acute bronchitis,* especially when the secretion is unusually free; also in *chronic cystitis* and *gonorrhea.*

Dose, two to five grains (0.13–0.32 Gm.), from four to six times a day, in pill or in emulsion.

Off. Prep.—Elixir Terpini Hydratis, *N. F.;* Elixir Terpini Hydratis et Creosoti, *N. F.*

TERRA SILICEA PURIFICATA. U. S.

PURIFIED SILICEOUS EARTH Ter. Sil. Purif. [Purified Kieselguhr, Purified Infusorial Earth]

"A form of silica (SiO_2) consisting of the frustules and fragments of diatoms, purified by boiling with diluted hydrochloric acid, washing, and calcining. It contains not more than 10 per cent. of water." *U. S.*

Kieselguhr is a form of earth consisting of fragments of frustules, or shells, of diatoms—which are microscopical unicellular algæ. Chemically it is an amorphous silicon dioxide and is therefore related to quartz which is a crystalline silica (see *Silex,* Part II). It is found in large deposits of greater or lesser purity in many parts of the world. It should not be confounded with kaolin whose chemical composition and physical properties are quite different.

Description and Physical Properties.—"A very bulky and very fine, odorless powder; white or light gray to pale buff in color. It readily absorbs moisture, retaining about four times its weight of water without the mixture becoming fluid. Purified Siliceous Earth is insoluble in water, acids, or in dilute solution of the alkali hydroxides.

"When ignited its color is not darkened (*organic impurities*), nor does it lose more than 10 per cent. of its weight (*moisture*). Digest 1 Gm. of Purified Siliceous Earth for fifteen minutes with 20 cc. of diluted hydrochloric acid, and filter: a 10 cc. portion of the filtrate, evaporated to dryness and ignited, leaves not more than 0.005 Gm. of residue. Boil 10 Gm. of Purified Siliceous Earth with 50 cc. of distilled water during ten minutes, replace any water lost by evaporation, and filter: the filtrate is colorless and neutral to litmus paper, and on adding 5 drops of potassium ferrocyanide T.S. to 5 cc. of the filtrate no blue color is produced (*soluble iron*). Add 1 Gm. of Purified Siliceous Earth to 25 cc. of diluted hydrochloric acid: no effervescence occurs (*carbonate*). Boil the mixture for ten minutes, replacing any water lost by evaporation, and filter: the addition of a few drops of barium chloride T.S. to the filtrate produces no turbidity (*sulphate*).

"Preserve in tightly-closed containers." *U. S.*

Uses.—Kieselguhr has widespread technical uses on account of its valuable physical properties. Chief among these are its chemical inertness and its power of absorbing large amounts of liquid. It is used to absorb nitroglycerin in the manufacture of dynamite; in transporting sulphuric acid as it forms a pulverulent compound containing 75 per cent. of sulphuric acid. It is also used as an absorbent for liquid manures. It is also used in fireproofing and insulating work because of its incombustibility and non-conductivity. It is used in polishing powders and soaps and in the composition of phonograph records. It differs importantly from the clays in that it has very slight *ad*sorbing powers. Because of this fact it is valuable in pharmacy as a filtering medium. It is difficult to obtain it of U. S. P. quality because none of the firms supplying it seem to be interested enough in it to remove the traces of iron and soluble impurities which are frequently observed in the commercial article. It may easily be purified by the same method as described under *Talcum.* It is also used in making dermatologic pastes.

THEOBROMINÆ SODIO-SALICYLAS. U. S. (Br.)

THEOBROMINE SODIO-SALICYLATE Theobrom. Sodio-Sal.

"A mixture of sodium theobromine [$C_7H_7O_2N_4Na$] and sodium salicylate [$NaC_7H_5O_3$] in approximately molecular proportions. It yields, when dried to constant weight at 110° C., not less than 46.5 per cent. of theobromine [C_7H_8-

O_2N_4] and not less than 35 per cent. of salicylic acid [$HC_7H_5O_3$]." *U. S.* "Theobromine and Sodium Salicylate, $Na_2C_{14}H_{12}N_4O_5$, may be obtained by combining sodium hydroxide, theobromine, and sodium salicylate in molecular proportions. Should be preserved in stoppered, amber-colored bottles." *Br.*

Theobrominæ et Sodii Salicylas. Theobromine and Sodium Salicylate, *Br.;* Theonasal; Diuretinum; Diuretin; Salicylas Natrii et Theobrominae Sodicae; Theobrominonatrium. Salicylicum, *G.*

Theobromine is a basic principle found in the chocolate bean (see *Cacao Præparata*). It was discovered by Woskresensky, who obtained it by the following method: The kernels are exhausted with water by means of the water bath; the solution is strained through linen, precipitated by lead acetate, and filtered; the filtered liquor is freed from lead by hydrogen sulphide, and evaporated; the brown residue is treated with boiling alcohol, and the liquor filtered while hot. Upon cooling, the theobromine is deposited in the form of a reddish-white powder, which is rendered colorless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch glasses, by which a brilliant white sublimate was obtained. According to O. Donker and C. Treumann, theobromine is contained not only in the cotyledons but also in the shells of the cacao seeds. Four kilos of the latter yielded 13.5 Gm. of pure theobromine.

F. P. Stroup (*Proc. Penna. Ph. A.,* 1919, 161) has suggested the potassium dichromate sulphuric acid test as a means of distinguishing between caffeine and theobromine. With caffeine a bright bluish-green color immediately appears, while with theobromine the color change is at first purple, subsequently changing to an olive green, and finally to the same bluish-green produced by caffeine.

Theobromine is a *dimethyl xanthin* (dimethyloxypurin) isomeric with theophylline and differing in the location of the methyl groups which in theophylline are in the 1–3 position and in theobromine are in the 3–7 position. It is found in cacao beans in amounts ranging from 0.9 to 3.0 per cent., and in very much smaller amounts in kola nuts. It is also related to caffeine, which is a tri-methyl xanthin.

Theobromine may combine with either bases or acids. The official preparation is a mixture of theobromine-sodium and sodium salicylate.

Properties.—"A white, odorless powder, having a sweetish, saline, and somewhat alkaline taste. It gradually absorbs carbon dioxide from the air with the liberation of theobromine, becoming incompletely soluble in water. It also frequently develops a characteristic odor. One Gm. of Theobromine Sodio-Salicylate is soluble in 1 cc. of water at 25° C. It is slightly soluble in alcohol.

"An aqueous solution of Theobromine Sodio-Salicylate (1 in 20) is strongly alkaline to litmus paper and to phenolphthalein T.S. When ignited, Theobromine Sodio-Salicylate yields a residue which colors a non-luminous flame intensely yellow and effervesces with acids. An aqueous solution of Theobromine Sodio-Salicylate (1 in 100), slightly acidulated with acetic acid, becomes violet on the addition of ferric chloride T.S. To about 0.05 Gm. of the precipitate obtained in the assay for Theobromine add 1 cc. of hydrochloric acid and about 0.1 Gm. of potassium chlorate and evaporate to dryness on a water bath: a reddish-yellow residue remains which becomes purple when moistened with a drop of ammonia T.S.

"Dried to constant weight at 110° C., Theobromine Sodio-Salicylate loses not more than 10 per cent. (*water*). A freshly prepared aqueous solution of Theobromine Sodio-Salicylate (1 in 20) is colorless or nearly colorless and is clear or at most opalescent. One-tenth Gm. of Theobromine Sodio-Salicylate dissolves in 2 cc. of sulphuric acid without effervescence (*carbonate*) and without producing more than a slight color (*readily carbonizable substances*). Dissolve 1 Gm. of Theobromine Sodio-Salicylate in 10 cc. of distilled water, add a few cc. of sodium hydroxide T.S., and shake the mixture with 10 cc. of chloroform. Separate the chloroform layer, evaporate it to dryness on a water bath, and dry to constant weight at 80° C.: the weight of the residue so obtained does not exceed 0.005 Gm. (*caffeine*).

"Preserve in well-closed containers." *U. S.*

"A white amorphous powder. No odor; taste sweetish and alkaline. Soluble in 1 part of *water;* soluble in *alcohol* (90 per cent.); insoluble in *ether,* and in *chloroform.* Aqueous solution (1 in 4) alkaline to *litmus* and colorless; when acidified with *acetic acid* yields a violet coloration with *T. Sol. of ferric chloride;* when neutralized with *hydrochloric acid* gives a white precipitate of theobromine, and the filtrate from this, on the addition of more of the acid, gives a precipitate of salicylic acid; the precipitated theobromine, washed with a little *water,* yields, when treated with *potassium chlorate* and *hydrochloric acid* as described under 'Caffeina,' a purple color. The aqueous solution also yields precipitates with *T. Sol. of mercuric chloride,* with solutions of alkaloidal salts, and with *N/10 solution of iodine.*" *Br.*

"**Assay for Theobromine.**—Dissolve about 2 Gm. of Theobromine Sodio-Salicylate, previously dried to constant weight at 110° C. and accurately weighed, in 10 cc. of warm distilled water, and titrate the solution with normal hydrochloric acid, using phenolphthalein T.S. as indicator: not more than 5.5 cc. of normal hydrochloric acid is required to neutralize 2 Gm. of the dried Theobromine Sodio-Salicylate. The solution should now be slightly alkaline to litmus paper or be made so by the addition of one or two drops of very dilute ammonia water. Allow to stand at from 20° to 25° C. for three hours, stirring occasionally, transfer the precipitate of theobromine to a dried and weighed filter of 9 cm. diameter, wash the precipitate and filter with four successive portions of 5 cc. each of ice-cold distilled water, and dry to constant weight at 100° C. To the weight of precipitate thus obtained add 0.13 Gm. (the approximate quantity of theobromine remaining in the liquid and washings). The total weight corresponds to not less than 46.5 per cent. of the weight of dried Theobromine Sodio-Salicylate taken. About 0.2 Gm. of the precipitate obtained in the assay for theobromine volatilizes when slowly heated, leaving only a negligible residue.

"**Assay for Salicylic Acid.**—Dilute the filtrate and washings obtained in the assay for theobromine with distilled water to exactly 50 cc., transfer 25 cc. of the liquid to a separator, add 10 cc. of diluted sulphuric acid, and extract the liberated salicylic with four successive portions of 25, 15, 10 and 5 cc. each of chloroform. Pass the chloroform solutions through a filter previously moistened with chloroform, and wash the filter and the stem of the funnel with a few cc. of hot chloroform. Evaporate the combined chloroform solutions to about 5 cc. at a temperature not exceeding 60° C., add 25 cc. of diluted alcohol which has been previously neutralized with tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal barium hydroxide until the pink color is restored. Each cc. of tenth-normal barium hydroxide corresponds to 0.01381 Gm. of salicylic acid ($HC_7H_5O_3$).

"Preserve in well-closed containers." *U. S.*

"Yields not less than 40 per cent. of theobromine and 35 per cent. of salicylic acid when tested by the following process: Dissolve 2 grammes of the Salicylate of Theobromine and Sodium in 10 millilitres of warm *water*, slightly acidify with *diluted hydrochloric acid*, add *solution of ammonia* until the reaction is faintly alkaline, and set aside for three hours at about 15.5° C., stirring frequently. Collect the precipitated theobromine on a tared filter, wash twice with 10 millilitres of *water*, dry at 100° C., and weigh the precipitate; it weighs not less than 0.8 gramme. Acidify the filtrate and washings with *hydrochloric acid*, shake with two successive quantities, each of 10 millilitres, of *ether*, evaporate the mixed ethereal solutions, dry the residue at 60° C., and weigh; it weighs not less than 0.7 gramme." *Br.*

Uses.—The effects of theobromine upon the system are very similar to those produced by caffeine except that it has relatively little influence upon the central nervous system. Because of this fact it is much less liable to produce wakefulness—although in some sensitive individuals it does act as a cerebral stimulant—and is not useful as a respiratory stimulant. The most important effect of theobromine upon the system is an increase in the secretion of urine. The mechanism of this action is doubtless the same as that of caffeine. Theobromine also is a powerful stimulant to the voluntary muscles, but because of its feeble effect upon the central nervous system is less useful than caffeine for the purpose of overcoming fatigue. It is used in medicine as a diuretic, especially in cases of *dropsy*. It is superior to caffeine in that because of its feeble influence over the central nervous system much larger doses can be administered than are permissible with caffeine.

Dose, from five to ten grains (0.32–0.65.), repeated at short intervals up to thirty or forty grains (2.0–2.6 Gm.) in 24 hours.

THEOPHYLLINA. U. S.

THEOPHYLLINE Theophyll.

"Dimethylxanthine [$C_5H_2(CH_3)_2.O_2N_4.H_2O$ 1:3]." *U. S.*

Theocin; Theophyllinum, *G.*

Theophylline belongs to a group of organic compounds related to uric acid and known as diureides or xanthin bases. It is also known as 1–3, dimethyl, 2–6, dioxypurine, and differs from caffeine in having one less methyl group. It forms crystalline salts with hydrochloric and nitric acids and with a number of metallic chlorides. It forms a soluble compound with sodium hydroxide. Caffeine may be prepared from it by methylation. Theophylline occurs in the mother liquors after extraction of caffeine from tea. It may be recovered by precipitating as a sparingly soluble compound with silver, which is later decomposed by hydrogen sulphide. The amount found naturally in tea is so small that most of the commercial product is of synthetic origin. It is made from ethyl cyanoacetate, which is the starting point for the synthesis of a number of the xanthine bases.

Description and Physical Properties.—"A white, crystalline, odorless powder having a bitter taste. It is stable in the air. One Gm. of Theophylline is soluble in 120 cc. of water and in 80 cc. of alcohol, at 25° C. It is more readily soluble in hot water; sparingly soluble in ether. It is readily soluble in solutions of potassium hydroxide and in ammonia water.

"Theophylline melts between 269° and 272° C. To about 0.01 Gm. of Theophylline, contained in a porcelain dish, add 1 cc. of hydrochloric acid and 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath: on inverting the dish over a vessel containing a few drops of ammonia T.S., the residue acquires a purple color which is destroyed by fixed alkalies. An aqueous solution of Theophylline yields with tannic acid T.S. a precipitate which is soluble in an excess of the reagent.

"A saturated aqueous solution of Theophylline is neutral to litmus paper. Theophylline loses not more than 9.5 per cent. when dried to constant weight at 100° C. (*water*). The ash from 0.1 Gm. is negligible. Two-tenths Gm. of Theophylline dissolves in 5 cc. of sulphuric acid without producing more than a faint yellow color (*readily carbonizable substances*). A clear solution is produced when 0.2 Gm. of Theophylline is dissolved in 5 cc. of potassium hydroxide T.S. or in 5 cc. of ammonia T.S. (*difference from caffeine, theobromine, or paraxanthine*)." *U. S.*

Uses.—In its effects upon the system, theophylline acts almost the same as its isomer, theobromine, and is used in medicine for precisely the same purposes. It appears, however, to be somewhat more irritant to mucous membrane, and is therefore more actively diuretic and also more likely to produce gastric disturbances. When used continuously over considerable periods of time the primary diuretic influence of theophylline may disappear, and the quantity of the urine return to its former low level, this despite increased doses of the drug. The explanation of this clinical observation is not yet forthcoming.

This drug is used more frequently in the form of one of its soluble compounds (see *Theocine Compounds,* Part II).

Dose, three to five grains (0.2–0.32 Gm.).

THUJA. N. F.

THUJA [Arbor Vitæ]

"Thuja consists of the dried, leafy, young twigs of *Thuja occidentalis* Linné (Fam. *Pinaceæ*). Thuja contains not more than 2 per cent. of its stems over 4 mm. in diameter or other foreign organic matter. Only the recently dried drug should be used." *N. F.*

Thuya; White Cedar; Arbor Vitæ; Herba Thujæ; Cèdre Blanc, *Fr.*; Lebensbaum, Weisses Ceder, *G.*

Arbor vitæ is a coniferous tree characterized by the appressed-imbricated leaves, the pointless cone-scales, and the broad wings extending all around the seeds. It attains a height of 20 m., and grows in swampy grounds from New Brunswick to Manitoba, south to North Carolina and Illinois, often forming extensive "cedar swamps." In Canada and the extreme northern parts of the United States it has been erroneously called *white cedar,* a name often applied to *Chamæcyparis thyoides* (L.) B. S. P., which latter is more properly called *Southern white cedar.* The wood is reddish, soft, fine-grained, and very durable and is much used for telegraph poles. The leaves, or small twigs invested with the leaves, have an agreeable, balsamic odor, specially when rubbed, and a strong, balsamic, camphoraceous, bitter taste. The commercial supplies of the drug are obtained from North Carolina, Virginia and Michigan.

Description and Physical Properties.—"*Unground Thuja.*—Twigs fan-shaped, flattened, bearing the scale-like, imbricated leaves appressed in four rows; leaves of the edges boat-shaped, the intermediate flat, those at the tips of the twigs very broad, the lower elongated, all bearing conspicuous glands on the back. Odor strongly balsamic, aromatic and pungent; taste camphoraceous, terebinthinate and bitter.

"*Powdered Thuja.*—Greenish to brownish green consisting chiefly of fragments composed of chlorenchyma and epidermal cells with broadly elliptical stomata from 0.025 to 0.040 mm. in length, the latter with guard cells having lignified walls; numerous long fibers with thick lignified walls and simple oblique pores." *N. F.*

A. Kawalier, of Vienna, found in them volatile oil, a bitter principle called *pini-picrin,* $C_{22}H_{36}O_{11}$—which occurs also in *Pinus sylvestris*—sugar, gelatinous matter, a variety of wax, resin, and tannic acid; also a peculiar crystallizable glucoside, *thujin,* to which he gives the formula $C_{20}H_{22}O_{12}$. It is of a citron-yellow color and an astringent taste, soluble in alcohol, inflammable, and when its alcoholic solution is heated with diluted hydrochloric or sulphuric acid it splits up into glucose and *thujigenin,* and by continuing the reaction another molecule of water is taken up by the latter and *thujetin,* $C_{14}H_{14}O_8$, is formed. The same chemist determined that the tannic acid of this plant is identical with *pinitannic acid,* which he had previously obtained from the leaves of *Pinus sylvestris* L. Thuja leaf oil is of a yellowish-green color and occurs to the extent of 0.5 to 1 per cent. The chief constituents are *alpha-pinene, lævo-fenchone,* and the isomeric ketone *dextro-thujone* which also occurs in the volatile oils of tansy, worm wood and sage. The specific gravity is 0.910 to 0.935; optical rotation $-5°$ to $-15°$; ester value 18 to 25.

Uses.—At one time thuja was used as an internal remedy in the treatment of intermittent fevers, rheumatism, etc., but is today no longer employed for this purpose. It is mildly counter-irritant and is sometimes used as a local application in rheumatic states. Howe (*Eclectic Med. Journ.,* 1880) recommends the local application of a tincture in the treatment of *warts, condylomata,* and other foreign growths, even asserting its value in *epithelioma* and *nævus.* Sicard and Larue (*Gaz. des Hop.,* 1909) state that the injection of a tincture into warts will cause their rapid disappearance. Thuja is occasionally employed internally in menstrual disorders, which perhaps finds some justification in the experiments of Prochnow (*A. I. P. T.,* xxi, p. 314) who found that it had a stimulating effect upon the isolated uterus similar to that of hydrastis. It has also been used especially by the eclectic physicians in various urinary disorders such as *enuresis* and irritability of the bladder. A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in *worms.* According to Hildebrand both fenchone and thujone act as stimulants to the heart muscle. (*A. E. P. P.,* xlviii.) F. K. Bailey has reported a case of poisoning in a girl, aged fifteen, who took sixteen drops of the oil of white cedar, and directly afterwards fell unconscious, with clonic spasms followed by epileptiform convulsions lasting at intervals for several hours. Long-continued irritation of the stomach resulted. (*N. R.*, 1872.)

Dose, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Fluidextractum Thujæ, *N. F.*

THYMOL. U. S., Br.

THYMOL

"A phenol [$C_6H_3.CH_3.OH.C_3H_7$ 1:3:4]." *U. S.* "Thymol, or isopropyl-metacresol, $C_{10}H_{14}O$, is a substance obtained from the volatile oils of Thymus vulgaris, *Linn.*, Monarda punctata, *Linn.*, and Carum copticum, *Benth. and Hook. f.* Purified by recrystallisation from alcohol." *Br.*

Acidum Thymicum; Thymic Acid; Methylpropylphenol; Camphre de Thym, Acide Thymique, *Fr.;* Thymolum, *P. G.;* Thymiansaure, Thymolkampher, *G.;* Timolo, *It.;* Timol, *Sp.*

This substance has attracted considerable attention from its possession of powerful antiseptic properties. It may be obtained by submitting the volatile oils of several plants to a prolonged refrigeration, under the influence of which it crystallizes. Thus, it has been obtained from *Monarda didyma* Linn., *M. punctata* Linn., *Thymus zygis* Linn. var. *gracilis* Boiss., *Ptychotis ajowan* (see *Oleum Ajowan*), *Mosula Japonica* and *Carum copticum* Benth. et Hook. filius. *Ocimum viride* Willd., a plant which is used in Liberia as an antiperiodic, and is said to be especially valuable owing to the fact that when growing in a room it will drive mosquitoes out of the apartment, as well as the medicinally active *O. gratissimum* of India, probably depend for their activities upon thymol. (*Proc. A. Ph. A.*, xxvi, 168.) Thymol is obtained from any of the oils in which it occurs by distilling off from these the larger part of the hydrocarbons and adding warm sodium hydroxide solution to the residue, which combines with the thymol. The mixture is diluted after a time with hot water, which causes the unattacked oil to rise to the top. From the sodium hydroxide solution hydrochloric acid sets the thymol free. This collects as an oily layer, which on cooling will crystallize if a crystal of thymol is added.

A process has been patented by M. Dinesman for making *synthetic thymol* from *p*-cymol (see *Ph. Centralh.*, Oct., 1901, 650).

Description and Physical Properties.—"Large, colorless, transparent crystals, having an aromatic, thyme-like odor, and a pungent, aromatic taste. One Gm. of Thymol is soluble in about 1000 cc. of water, about 1 cc. of alcohol, 0.7 cc. of chloroform, 1.5 cc. of ether, and in 1.7 cc. of olive oil, at 25° C. It is soluble in glacial acetic acid and in fixed or volatile oils.

"Thymol melts between 48° and 51° C., remaining liquid at a considerably lower temperature. Thymol is heavier than water, but when liquefied by fusion it is lighter than water. An alcoholic solution of Thymol (1 in 20) is neutral to litmus paper, and is optically inactive.

"When Thymol is triturated with about an equal weight of camphor or menthol, the mixture liquefies. Dissolve a very small crystal of Thymol in 1 cc. of glacial acetic acid, and add 6 drops of sulphuric acid and 1 drop of nitric acid: the liquid assumes a deep bluish-green color by reflected light. Heat about 1 Gm. of Thymol in a test tube in a water bath with 5 cc. of a 10 per cent. solution of sodium hydroxide: a clear, colorless, or pale red solution is formed, which becomes darker on standing, without the separation of oily drops. Upon the addition of a few drops of chloroform to this solution and agitating the mixture, a violet color is produced. Volatilize about 2 Gm. of Thymol on a water bath: not more than 0.05 per cent. of residue remains." *U. S.*

"Large, oblique prismatic crystals, sinking in water at 15.5° C. Melting point from 50° to 51° C. Completely volatilised on a water-bath. Odor recalling that of thyme; taste pungent, aromatic. Almost insoluble in *water;* freely soluble in *alcohol* (90 per cent.), in *ether,* and in *solution of sodium hydroxide.* A solution of Thymol in half its volume of *glacial acetic acid,* warmed with an equal volume of *sulphuric acid,* assumes a reddish-violet color." *Br.*

Robert Meldrum (*Chem. News,* cxi, 193) has attempted to reconcile the conflicting melting points which have been ascribed to thymol and states that the variations and wide range recorded are due to supercooling. He gives the correct solidifying point at 48.2° to 49.2° C. Moles and Marquina (*J. S. C. I.*, 1919, xxxviii, 388A) propose a method of assay for thymol based upon iodometric titration.

Uses.—Thymol was originally introduced as a disinfectant for the same range of purposes for which phenol is employed. The advantage claimed for it was a more agreeable odor. Its drawbacks are its strong local irritant effect and its sparing solubility in water. Concerning its antibacterial powers the findings of different investigators have been contradictory, thus Cooper (*B. M. J.*, 1912, i, p. 1235) finds that in the presence of organic matter it is eight times as powerful as phenol and in the absence of organic matter twenty-five times as strong. On the other hand Schmidt (*Z. P. C.*, 1910, lxvi, p. 412) asserts that it has no germicidal value against vigorous bacteria. It is probably superior to phenol in antibacterial power. It is to-day rarely employed as a surgical disinfectant, but is an ingredient in many of the antiseptic mixtures intended for use upon mucous cavities, such as the National Formulary *Antiseptic Solution.* Its value for these purposes, however, is greatly reduced because of its powerful local irritant action; it is scarcely possible to apply it in stronger solution than one part in a thousand without considerable discomfort. Thymol is also used as a gastro-intestinal disinfectant in *fermentative gastritis, enteritis,* and similar conditions. For this purpose it may be given in doses of two to five grains (0.13–0.32 Gm.) several times a day.

Perhaps the most important modern use of thymol is as a vermifuge. It is efficient against the *tape-worm* and probably all forms of intestinal parasites, but is especially employed against the *hook-worm*. For this purpose it is necessary to use it in such large doses that there is danger of poisoning unless absorption be guarded against. The method employed by the Porto Rican Commission as reported by Schultz (*J. A. M. A.*, 1911, lvii, p. 1102) was as follows: If the patient be fairly robust, from fifteen to thirty grains (1–2 Gm.) were given mixed with an equal quantity of sugar of milk, and administered on an empty stomach; this dose is repeated in two hours, and two hours later followed by a vigorous purge, either magnesium sulphate or compound cathartic pills. It is essential that the intestines be as empty as possible as the presence of various foodstuffs encourages absorption. Castor oil should be avoided as the cathartic for a similar reason. The symptoms of thymol poisoning are nausea, vomiting, headache, ringing in the ears, dizziness, muscular weakness, thready pulse, and fall of bodily temperature.

Dose, two to fifteen grains (0.13–1.0 Gm.).

Off. Prep.—Cataplasma Kaolini, *N. F.;* Liquor Antisepticus, *N. F.;* Liquor Aromaticus Alkalinus, *N. F.;* Nebula Aromaticus, *N. F.;* Nebula Thymolis, *N. F.;* Petroxolinum Sulphuratum Compositum, *N. F.;* Pulvis Antisepticus, *N. F.*

THYMUS. N. F.

THYME

"Thyme consists of the dried leaves and flowering tops of *Thymus vulgaris* Linné (Fam. *Labiatæ*). Thyme contains not more than 3 per cent. of stem over 1 mm. in diameter or other foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

Garden Thyme; Common Thyme; Herba Thymi *P. G.;* Thymian, *G.;* Thym, *Fr.;* Tomillo, *Sp.*

The thyme is a small shrub growing to a height of about a foot, with ascending, brown to purplish, branches and oblong-lanceolate, grayish-green leaves; the pale purple flowers are strongly bilabiate and arranged in dense cymes both axillary and terminal. The plant is a native of south-central Europe and is widely cultivated in France, Germany, Spain and the United States. The commercial supplies of the crude drug come chiefly from Italy, Spain and France.

The whole plant is aromatic and yields from about 0.5 per cent. of a volatile oil, which is official (see *Oleum Thymi*). This oil contains as its most important ingredient thymol, but it is stated that the oil from the Spanish plant yields carvacrol, rather than thymol with which it is isomeric.

Description and Physical Properties.—"*Unground Thyme.*—Stems quadrangular, about 0.5 mm. in diameter, grayish brown or purplish in color, pubescent, nodes from 5 to 20 mm. apart, occasionally with the opposite leaves attached; leaves linear, linear-lanceolate, or ovate, oblong, from 0.5 to 6 mm. in length and from 0.5 to 2 mm. in breadth, summit acute, base obtuse tapering into a petiole from 0.5 to 2 mm. in length, margin revolute, upper surface grayish green, puberulent, with numerous one-celled, thick-walled, non-glandular hairs; lower surface grayish, pubescent, with non-glandular, one- to four-celled, thick-walled, rough simple hairs, up to 0.135 mm. in length and usually curved at the first joint in the bases; numerous compound glandular secreting hairs, with short one-celled stalk occurring chiefly on the upper surface and depressed in the cuticle, which give the leaf a glandular-punctate appearance; inflorescence in about twelve-flowered axillary whorls; flowers polygamous, calyx tubular, about 4 mm. in length, ovoid or slightly curved on the lower side near the base, from nine- to twelve-nerved, pubescent, the throat bearded with straight simple hairs up to 1 mm. in length, bilabiate, upper lip three-toothed, lower lip with two hairy, ascending attenuate divisions, corolla about twice as long as the calyx, purplish, smooth within, slightly pubescent without, upper lip emarginate, lower spreading and three-lobed, stamens slightly didynamous and exserted, stigma bifid; nutlets about 0.5 mm. in diameter, spheroidal and finely tuberculate. Odor agreeable, aromatic; taste aromatic and warming.

"*Powdered Thyme.*—Light green; short sharp-pointed unicellular non-lignified non-glandular hairs about 0.060 mm. in length; 2- to 3-celled non-lignified, uniseriate, non-glandular hairs of two types, both with papillose walls, one from 0.200 to 0.300 mm. in length with the apical cell sharp-pointed, the other with the apical cell somewhat curved or hooked; glandular hairs of two types, one with a short stalk embedded in the epidermal layer and a unicellular head, the other with an 8- to 12-celled head but without a stalk; fragments of leaf tissue composed of chlorenchyma with vascular tissue and epidermal cells with broadly elliptical stomata the latter about 0.025 mm. in length; fibers with thick lignified walls and simple pores; pollen grains, nearly spheroidal about 0.020 mm. in diameter." *N. F.*

The chief adulterants of thyme have been the leaves and flowering tops of *Origanum creticum* or "*Spanish hops*" and of *O. Dictamnus* or "*Cretan Dittany.*" The former may be detected by its yellowish-brown stems, palmately 5-veined, ovate leaves, papillated nutlets and oil containing carvacrol; the latter by its elliptical, densely hairy leaves and volatile oil containing pulegone.

Uses.—The therapeutic value of thyme probably depends entirely upon its volatile oil and it is very doubtful whether the whole plant has any advantage over the volatile oil. Of recent years, however, it has come into considerable popularity, largely because of the advertisement of a proprietary preparation, as a remedy for *bronchitis* and especially *whooping cough.*

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Thymi, *N. F.;* Syrupus Thymi, *N. F.;* Syrupus Thymi Compositus, *N. F.*

THYMOLIS IODIDUM. U. S.

THYMOL IODIDE Thymol. Iod.

"Thymol Iodide is a mixture of iodine derivatives of thymol, principally dithymol-diiodide [$(C_6H_2.CH_3.C_3H_7.OI)_2$], containing, when dried to constant weight over sulphuric acid, not less than 43 per cent. of iodine." *U. S.*

Dithymoldiiodide; Aristol; Aristolum; Diiodothymolum; Diiodo dithymolum, *Fr. Cod.;* Dithymol Biiodé, *Fr.;* Dithymoljodid, Annidalin, Thymotol, *G.;* Timol Biyodado, Aristol, *Sp.*

Preparation.—*Thymol Iodide* contains about 45 per cent. of iodine; it is the product of the condensation of two molecules of thymol and the substitution of the hydrogen in the hydroxyl group in each by iodine. It may be prepared by decomposing a solution of iodine in potassium iodide by an alcoholic solution of thymol. The Cincinnati Academy of Pharmacy published the following formula for thymol iodide: Thymol, 50 Gm.; potassium iodide, 58 Gm.; sodium hydroxide, 50 Gm.; water, to make 500 cc.; solution of chlorinated soda, to make 3000 cc. Dissolve the thymol, potassium iodide, and sodium hydroxide in sufficient water, add the solution of chlorinated soda, collect the precipitate on a filter and wash it with water until it is free from chlorides. Remove the precipitate and dry it carefully at a temperature not exceeding 20° C. Reduce it to powder and keep it in a well-stoppered dark bottle. (*Am. Drug.,* 1898, 130.) The French Codex directs that two solutions be made, one by dissolving 16 Gm. of sodium hydroxide and 15 Gm. of thymol in sufficient water to make the solution measure 300 cc. The other solution is made by dissolving 60 Gm. of iodine and 80 Gm. of potassium iodide in enough water to make the solution measure 300 cc., the latter solution is added gradually to the alkaline solution of thymol with constant stirring; the resulting brown precipitate is washed with water and the product dried between 40° and 50° C.

The structural formula of thymol iodide usually assumes the compound to be a hypoiodous ether of the phenolic group. J. Bonjault contests this view and states that the iodine replaces the hydrogen of the hydrocarbon nuclei. (*J. P. C.,* 1918, xvii, 221.)

Description and Physical Properties.—"A reddish-brown or reddish-yellow, bulky powder with a very slight, aromatic odor. Thymol Iodide is insoluble in water and in glycerin; slightly soluble in alcohol; readily soluble in chloroform, ether, collodion, and in mixed or volatile oils, usually leaving a slight residue. It is insoluble in cold or in hot solutions of the fixed alkali hydroxides. When heated with concentrated sulphuric acid, it is decomposed with the separation of iodine.

"Heat about 0.5 Gm. of Thymol Iodide, accurately weighed, in a porcelain crucible until charred, cool, add 5 drops of sulphuric acid, and ignite to constant weight: not more than 1.5 per cent. of residue remains. Digest 0.1 Gm. of Thymol Iodide with 50 cc. of warm, distilled water for 10 minutes, filter, cool, add 5 drops of diluted nitric acid and 1 cc. of silver nitrate T.S.: the turbidity produced, if any, is not greater than that in a control test made with 1 cc. of a solution containing 0.002 Gm. of potassium iodide (*soluble iodides*). Shake 0.5 Gm. of Thymol Iodide with 10 cc. of distilled water and filter the mixture: the filtrate is not alkaline to litmus paper (*alkalies*), nor is it colored blue upon the addition of a few drops of starch T.S. (*free iodine*).

"**Assay.**—Mix thoroughly about 0.25 Gm. of Thymol Iodide, previously dried to constant weight over sulphuric acid and accurately weighed, with about 3 Gm. of anhydrous potassium carbonate. Place the mixture in a platinum crucible, cover with about 1 Gm. of anhydrous potassium carbonate, and heat moderately, gradually increasing the heat, but not exceeding a dull redness, until the mass is completely carbonized. Extract the residue with boiling distilled water and wash it on a filter with boiling distilled water until the washings cease to produce an opalescence with silver nitrate T.S. Heat the combined washings, which measure about 150 cc., on a water bath and add an aqueous solution of potassium permanganate (1 in 20) in small portions, until the hot liquid remains permanently pink. Add just enough alcohol to remove the pink tint, cool to room temperature, dilute to 200 cc., mix well, and filter through a dry filter, rejecting the first 50 cc. of filtrate. To 100 cc. of the subsequent clear filtrate, add about 1 Gm. of potassium iodide (free from iodate) and an excess of diluted sulphuric acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, adding starch T.S. near the end of the titration. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.002115 Gm. of iodine.

"Preserve in well-closed containers, protected from light." *U. S.*

Osseward (*Proc. A. Ph. A.,* 1901, 176) obviates the difficulty of obtaining smooth ointments of thymol iodide (which most dispensers have experienced when proceeding in the usual way) by adding sufficient ether to 1 oz. of thymol iodide placed in a dry mortar, to form a paste, then stirring in 1 oz. of olive oil until a smooth paste is obtained; the ether can be dissipated during the stirring, and this 50 per cent. mixture used in making ointments by incorporating with fatty substances.

Uses.—Thymol iodide is used as a non-toxic and non-irritant dusting powder for *wounds.* It has the same range of usefulness for this purpose as iodoform over which it has the great advantage of being comparatively odorless. According to Shamberg and Kolmer (*J. A. M. A.*, 1914, lxii, p. 1950), it restrains the growth of *Staphylococcus aureus* when present in the proportion of 0.5 per cent. Despite, however, its superiority in direct antiseptic action to iodoform, it is not held in as high esteem by most surgeons. It is also used as a dusting powder in various moist *skin diseases,* such as weeping eczemas, and Daxenberger (*Heilkunde,* 1908) recommends a 10 per cent. solution in olive oil as a local application in *atrophic rhinitis* and *fissure in ano* as well as various *skin diseases.*

Dose, from two to three grains (0.13–0.2 Gm.).

THYROIDEUM. U. S. (Br.)

THYROID Thyroid. [Thyroideum Siccum U. S. P. IX]

“Thyroid is the cleaned, dried, and powdered thyroid gland, previously deprived of connective tissue and fat. It is obtained from domesticated animals which are used for food by man. Thyroid contains not less than 0.17 and not more than 0.23 per cent. of iodine in thyroid combination, and must be free from iodine in inorganic or any other form of combination than that peculiar to the thyroid gland. One part corresponds to approximately 5 parts of the fresh glands.” *U. S.* “Dry Thyroid is a powder prepared from the fresh and healthy thyroid glands of the sheep. Remove the external fat and connective tissue from the thyroid glands taken from the sheep immediately after killing. Cut the glands across, and reject any which contain cysts, are hypertrophied, or are otherwise abnormal. Mince finely the healthy glands, and dry at a temperature of 30° to 40° C.; powder the dried product; remove all fat by washing with *petroleum spirit;* again dry the residue.” *Br.*

Thyroideum Siccum, *Br.;* Dried Thyroids; Glandulæ Thyroideæ Siccæ; Desiccated Thyroid Glands, Schilddrüsen, Getrocknete Schilddrüsen, *G.*

The thyroid body is a glandular structure found in all mammals, located in the front of the neck. It consists of two oval lobes usually connected by an “isthmus” and differs considerably in size even in animals of the same species. The human thyroid averages from 30 to 40 Gm. in weight, but in the condition known as goiter, sometimes forms a huge tumor. The gland secretes a substance necessary for the health of the animal, which is poured directly into the blood vessels with which it is richly supplied. Its use as a medicine is because of the secretion retained in it.

Description and Physical Properties.—“A yellowish, amorphous powder, having a slight, characteristic odor.

“Thyroid contains not more than 6 per cent. of moisture. Ash: not more than 5 per cent.” *U. S.*

“A light, dull-brown powder, with a very faint meat-like odor and taste; free from any flavor of putrescence. Liable to become damp on exposure to the air, and to deteriorate.” *Br.*

Assay.—“Mix 1 Gm. of Thyroid in a nickel crucible of about 125 cc. capacity, with 15 Gm. of a mixture composed of 138 parts by weight of anhydrous potassium carbonate, 106 parts of anhydrous sodium carbonate, and 75 parts of potassium nitrate. Spread an additional 5 Gm. of this fusion mixture evenly over the surface. Heat the crucible over a free Bunsen flame until no further carbonization is observed, cool, and dissolve the residue in about 150 cc. of distilled water, warming to hasten solution. Transfer this solution to an Erlenmeyer flask of about 500 cc. capacity, and add approximately 50 cc., or its equivalent, of a fresh solution of chlorinated soda (containing 2.5 per cent. of chlorine by weight). Treat the mixture with enough phosphoric acid, diluted with an equal volume of distilled water, to produce an appreciable yellow tint of free chlorine, add about 10 cc. more of phosphoric acid, diluted with an equal volume of distilled water, and boil for one-half hour or until the volume has been reduced to about 150 cc. Cool the liquid, add 10 cc. of a freshly prepared aqueous solution of potassium iodide (1 in 100), and titrate the liberated iodine with freshly prepared two-hundredth-normal sodium thiosulphate, starch T.S. being used as indicator just before the end of the reaction. Each cc. of two-hundredth-normal sodium thiosulphate used corresponds to 0.0001058 Gm. of iodine derived from thyroid glands.” *U. S.*

Various attempts to develop a biological method for the standardization of thyroid preparations have been made. The two most promising are those based upon (1) the metamorphosis of tadpoles and (2) alterations in susceptibility towards acetonitrile.

It is well established that thyroid feeding hastens the development of tadpoles into frogs. Rogoff (*J. P. Ex. T.,* 1917, x, p. 199) has developed a method based upon this principle which he claims will detect variations of 10 per cent. in the activity of preparations. Jensen (*Ph. Era,* 1921, liv, p. 143) suggests the use of the axolotl (*Ambystoma Mexicanum*). This is an amphibian which normally does not develop beyond the larval (tadpole) stage but, according to Jensen, if fed with thyroid gland undergoes a similar metamorphosis to other amphibians. The acetonitrile test was brought forward by Hunt and Seidl (*J. P. Ex. T.,* 1910, ii, p. 15). They found that thyroid feeding alters the resistance of mice to certain poisons, diminishing the susceptibility to acetonitrile but increasing them to morphine. They have suggested the lessening of the sensitiveness to acetonitrile as a test of the activity of samples of the drug.

The attempt to isolate an active principle from the thyroid has engaged the attention of physiological chemists for more than thirty years. In 1895 Baumann (*Zeit. P. C.,* xxi) described a principle, *thyroiodine* (*iodothyrine*), which possessed many of the physiological properties of the gland, but it was subsequently shown not to be a pure chemical individual. Pick and Pilenes (*Z. E. P. T.*, 1909, vii, p. 518) prepared a thyro-globulin by precipitation from an aqueous extract by means of ammonium sulphate. In 1915 Kendall separated a crystalline substance *thyroxin,* which has received official recognition, but it is not yet definitely established as the sole active constituent (see *Thyroxinum*).

Uses.—The thyroid gland is one of those organs, called endocrine, which furnish an internal secretion necessary for the health of the body. Its congenital absence leads to the condition called *cretinism,* which is chiefly characterized by: a failure of growth both mental and physical, a lack of ossification in the bones, general sluggishness, the deposit in the subcutaneous tissues of a peculiar jelly-like material, which causes an appearance resembling that of general dropsy, and usually sub-normal temperatures. Its removal in adults leads to an analogous symptom-complex called *myxedema.* In this state there is the same deposit beneath the skin giving the appearance of a dropsy, from which, however, it can be differentiated by the fact that the skin does not pit on pressure. There is mental sluggishness, a slowing of the pulse and usually a lowering of the bodily temperature. It is probable that there are diseased conditions of the system in which there is a partial but not complete failure of its secretion. The symptoms supposed to indicate such a state of hypo-thyroidism are a thick dry skin, loss of hair, depression of sexual functions, accumulation of fat, increased tolerance for sugar, and a subnormal body temperature. The administration of the thyroid body or its active principle to healthy animals causes an increase in the metabolism with consequent tendency for elevation of the temperature and a loss of body weight. There is usually increased rapidity of the pulse, nervous restlessness often with tremors, and a tendency to insomnia. The loss in bodily weight is due chiefly to the oxidation of the adipose tissue, but is accompanied, especially when the diet is restricted, by destruction of the nitrogenous (protein) substances of the body. There is usually also an increase in the number of mononuclear leukocytes of the blood. Although the single dose produces no very obvious changes in the bodily functions, Asher and Flack (*Z. B.*, 1911, lv, p. 83) have shown that the injection of this drug increases the irritability of the vasomotor center which observation has been confirmed by other observers. It is this increased sensitiveness that causes the extreme reaction to epinephrine, which is sometimes used as a diagnostic test (see under *Diagnostic Tests,* Part II).

As a medicine the thyroid is used first to combat those symptoms which are due to the absence of its secretion, either partial or complete, congenital or acquired. In addition to those symptoms already described as *myxedema* and *cretinism,* there are many physicians who attribute various obscure chronic disorders, especially those that occur during the climacteric, to diminished activity of the thyroid gland and consequently recommend the use of this drug. Because of the fact that thyroid feeding causes a loss of weight, it has been largely used in cases of *obesity,* even those that are not dependent on thyroid deficiencies. Many of the "antifat" nostrums upon the market contain thyroid. While there is no doubt that the thyroid will cause a loss of excessive corpulence, the injudicious use of it is accompanied with considerable danger, especially of the production of cardiac disturbances which may seriously injure the health. Means (*J. A. M. A.*, 1921, lxxvii, p. 792) strongly deprecates the use of the thyroid in any case of obesity, which is not due to subnormal metabolism.

In addition to these states in which the drug is obviously of value, it has been used in a more or less empiric manner in a large number of other disorders. There are indeed few diseases, either acute or chronic, for which the thyroid gland has not been recommended by someone. Among those conditions in which there is more or less suggestive evidence of its usefulness may be mentioned uterine disorders, especially *metrorrhagia;* certain types of *chronic nephritis* (see Epstein, *A. J. M. S.*, 1922, clxiii, p. 167); diseases of the bones as *ununited fractures, osteomalacia,* and *rheumatoid arthritis,* certain skin diseases especially *psoriasis, hay fever, asthma, cancer, hemophilia,* etc.

In myxedema it is generally well to begin with relatively large doses, about five grains (0.32 Gm.), until the accumulated symptoms due to the prolonged lack of thyroid secretion have abated, and afterwards continue the use of the drug in smaller quantities. For other conditions it is generally well to begin with smaller doses, one or two grains (0.06–0.12 Gm.), three times a day, gradually increasing if necessary, until palpitation of the heart or excessive nervousness indicates that the physiological limit or the therapeutic purpose is obtained. In any case, during the administration of the drug the occurrence of any of the symptoms of hyper-thyroidism should be the immediate signal for the withdrawal of the drug.

Among the various preparations of thyroid upon the market may be mentioned the following: *Iodothyrin* (*thyro-iodine*) appears commercially diluted with milk sugar to a strength equal to that of the fresh gland. The dose is ten to thirty grains (0.65–2.0 Gm.). *Thyroprotein,* standardized to contain 0.33 per cent. of iodine. *Thyraden,* dose two to eight grains (0.13–0.5 Gm.). *Thyrein,* said to be identical with iodothyrin. *Thyroidin,* a commercial preparation corresponding to the official dried gland. *Thyreoidin* Notkin, dose, one-sixth grain (0.01 Gm.).

It is said also to be useful for hypodermic administration in the form of a one-half per cent. solution. *Thyron* or *tyron,* prepared by treating thyroid gland with tannic acid.

Dose, of dried thyroids, from one to five grains (0.06–0.32 Gm.).

THYROXINUM. U. S.

THYROXIN Thyrox.

"Thyroxin [$(C_8H_5ONI_3).C_2H_4COOH$] is an active principle obtained from the thyroid gland, and contains not less than 63 per cent. of iodine." *U. S.*

This substance was discovered by E. C. Kendall (*J. Bi. Chem.,* 1915, xx, p. 501) who has also determined its chemical constitution to be a di-iodo-dihydroxy-indol (*J. A. M. A.,* 1918, lxxi, p. 871). The proportion in the thyroid body is from 0.025 per cent. to 0.001 per cent. It is prepared by first treating fresh or desiccated thyroid with a hot aqueous 5 per cent. solution of sodium hydroxide. The liquid is then filtered to separate insoluble soaps and the filtrate is cooled and acidified. The precipitate, which comprises only about 1 per cent. of the weight of the glandular substance used, is redissolved in sodium hydroxide solution and reprecipitated with hydrochloric acid. This second precipitate is then dried, dissolved in 95 per cent. alcohol and the liquid is carefully neutralized with sodium hydroxide. The solution is then filtered and the filtrate treated with a saturated aqueous solution of barium hydroxide, after another filtration carbon dioxide is passed into the liquid to remove barium. The filtered alcoholic solution is then subjected to distillation to recover the alcohol, the residue acidified with hydrochloric acid and the precipitate collected and dissolved in a weak solution of sodium hydroxide in strong alcohol. The solution is again treated with carbon dioxide, this time to precipitate sodium carbonate, and the alcohol again removed and recovered by distillation; upon standing a mono-sodium salt of thyroxin separates. This is further purified by a repetition of the foregoing precipitation processes, dissolving it in alkaline alcohol and using acetic acid as the precipitating agent. By this process about one ounce of thyroxin is obtained from over three tons of fresh thyroids.

Description and Physical Properties.—"White or slightly yellow, needle-like, odorless crystals or powder. Thyroxin is insoluble in water and practically insoluble in alcohol or other usual organic solvents, but in the presence of mineral acids it dissolves in alcohol. It is soluble in solutions of the alkali hydroxides and when alkaline solutions are saturated with sodium chloride the sodium salt of thyroxin separates.

"Ignite a few milligrams of Thyroxin with about 0.1 Gm. of sodium carbonate, dissolve the residue in 2 cc. of distilled water, acidulate with acetic acid, add 1 cc. of chloroform and a few drops of chlorine T.S.: the chloroform acquires a violet color.

"The ash from 0.01 Gm. is negligible. Dry about 0.02 Gm. of Thyroxin over sulphuric acid for twenty-hour hours: the loss in weight is negligible (*water*). Shake 0.01 Gm. of Thyroxin with 10 cc. of distilled water during five minutes, and filter. Acidulate the filtrate with one drop of diluted nitric acid, and add 3 drops of tenth-normal silver nitrate: the turbidity so produced is not greater than that produced in a control test by one drop of fiftieth-normal hydrochloric acid (*soluble iodides*).

"**Assay.**—Mix about 0.02 Gm. of Thyroxin, previously dried over sulphuric acid for twenty-four hours and accurately weighed, with about 0.5 Gm. of anhydrous potassium carbonate in a small platinum crucible. Cover the mixture with an additional 1 Gm. of anhydrous potassium carbonate, and heat gradually until it is completely decomposed. Treat with distilled water and transfer to a 100 cc. graduated flask. Heat the solution on a water bath and add potassium permanganate solution (1 in 20), drop by drop, until the liquid remains pink. Then add, drop by drop, just enough alcohol to discharge the pink color, cool, and dilute to the mark with recently boiled and cooled distilled water. Mix well and filter through a dry filter into a dry flask rejecting the first 20 cc. of the filtrate. To 50 cc. of the filtrate add about 0.5 Gm. of potassium iodide and 30 cc. of diluted sulphuric acid, and titrate the liberated iodine with two-hundredth-normal sodium thiosulphate, using starch T.S. as indicator towards the end. Correct for any iodine liberated in a blank made with the same quantities of distilled water, sulphuric acid, and potassium iodide. Each cc. of two-hundredth-normal sodium thiosulphate corresponds to 0.0001058 Gm. of iodine." *U. S.*

Uses.—While it seems well established that thyroxin is a pure chemical substance and that it possesses some of the physiological properties of the thyroid secretion, especially the power of increasing the metabolic rate, Hunt (*A. J. P.,* 1923, lxiii, p. 257 and *J. P. Ex. T.,* xxi, p. 199) has reached the conclusion that it does not fully represent the physiological activity of the thyroid gland. He found that in proportional dose it had less effect upon the development of growing animals and also was less efficient in protecting mice against his acetonitrile test. The drug must be regarded as still in the experimental stage, but it is being used with apparent success in the treatment of many of those conditions in which the whole gland is of service. It may be administered either by mouth or by intravenous injection.

Dose, from one three-hundredth to one-fiftieth of a grain (0.2 to 1 Mgm.). Jackson (*Illinois Med. J.,* 1925) has found that 50 milligrammes of thyroxin, administered intravenously, is required to bring the basal metabolic rate of a myxedematous patient to within normal limits. A variable daily dose of from 0.8 to 2 milligrammes of thyroxin by mouth is required to maintain this level. It is stated that 1 milligramme (1/60 grain) daily in a normal person if continued will eventually cause toxic symptoms.

TINCTURÆ. U. S.

TINCTURES

"Tinctures are liquid preparations made by extracting the useful principles from vegetable or animal drugs by appropriate menstrua or solvents containing alcohol. Tincture of ferric chloride and tincture of iodine are exceptions, being alcoholic solutions of chemicals." *U. S.*

Teintures (Alcooliques) Alcoolés, *Fr.;* Tinkturen, *G.;* Tinture alcooliche, *It.;* Tinturas alcoholicas, *Sp.*

Tinctures, in the pharmaceutical sense of the term, are alcoholic solutions of medicinal substances, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures.* The advantages of alcohol as a menstruum are that it dissolves principles which are sparingly, or not at all, soluble in water, and contributes to their preservation when dissolved, while it leaves behind some inert substances which are dissolved by water. In no instance, however, is dehydrated alcohol employed. Because of the slight amount of water in it, official alcohol dissolves more or less of substances which are insoluble in dehydrated alcohol, while its solvent power in relation to bodies soluble in that fluid is sufficient for all practical purposes. A hydroalcoholic menstruum is often preferable to official alcohol, as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, while at the same time it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating. In such cases the proper proportion of alcohol in the menstruum has been determined experimentally. Official diluted alcohol, which is of approximately the same strength as proof spirit, is frequently directed as a menstruum for tinctures. The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consists of equal volumes of official alcohol and water, and has the sp. gr. of about 0.936 at 15.56° C., while the British has four official diluted alcohols—70, 60, 45, and 20 per cent. Undiluted alcohol, or rectified spirit as it was formerly called, is preferred as a solvent when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of resins, camphor, and the essential oils. The presence of water is here injurious, by diluting the menstruum, which interferes with its solvent power. Thus, water added to an alcoholic solution of one of these bodies produces a precipitate. Diluted alcohol, or proof spirit, is employed when the substance is soluble both in alcohol and in water; or when one or more of the ingredients are soluble in the one fluid and one or more in the other, as in the case of vegetable bodies which contain extractive or tannin, or the natural salts of the alkaloids, or gum united with resin or volatile oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used. In the preparation of the tinctures, the drug should be dry, and properly comminuted. It is usually better in a moderately fine than in a very fine powder; the proper degree of pulverization varies according to the ease with which the menstruum extracts the soluble principles. The recommendations of the International Protocol included the use of the 70 per cent. alcohol for the various tinctures, but as this has not proven to be the best menstruum for some drugs, the U. S. P. has not always followed the suggestion.

"Tinctures of potent drugs are made of the strength of 10 Gm. of drug in 100 cc. of tincture, to conform to the Brussels Protocol. The other tinctures vary in the proportion of drug in the finished tincture, but many of these are made of the strength of 20 Gm. of drug in 100 cc. of tincture. Tinctures, with few exceptions, are made by percolation. Maceration or solution is preferred when, from its physical character, the drug is not suitable for percolation. The majority of official tinctures are prepared by one of the type processes described. The process to be followed is directed in each formula with such modification as may be necessary. A number of drugs require special manipulation for the preparation of satisfactory tinctures, and the formulas for these will be found in full in the text. Where it has been possible to standardize the tinctures, standards and assays have been provided. Tinctures should be stored in tightly-stoppered bottles, in a cool place, protected from light." *U. S.*

Type Process P—Percolation.—"Moisten the powdered drug or mixed drugs designated in the formula with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Transfer it to a precolator, pack it firmly, unless otherwise directed, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the menstruum to make the finished tincture measure 1000 cc., and mix thoroughly.

"*Modification for Assayed Tinctures.*—In tinctures that are directed to be assayed, allow the percolation to proceed until the percolate measures 950 cc. Assay a portion of this percolate as directed and from the alkaloidal content thus determined, or from the biological activity, ascertain by calculation the strength of the remainder of the liquid, and, make the finished tincture conform to the required standard, adding sufficient of the menstruum if necessary, and mix thoroughly." *U. S.*

Type Process M—Maceration.—"Macerate the drug or mixed drugs designated in the formula in a stoppered container, in a moderately warm place, with 750 cc. of the prescribed solvent (unless a different amount is specified in the formula). Continue the maceration with frequent agitation during three days or until active constituents of the drug are practically extracted. Transfer the mixture to a filter, and, when the liquid has drained off, gradually wash the residue on the filter with enough of the solvent directed to make the filtrate measure 1000 cc., and mix thoroughly." *U. S.*

The British Pharmacopœia in the *Appendix IX* (see Part III) has provided detailed instruction for both percolation and maceration processes.

Tinctures were at one time universally prepared by maceration or digestion. The U. S. Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. In several instances in which maceration is ordered in the U. S. Pharmacopœia, maceration for three days is directed, but the Br. process requires seven days. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stoppered, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration, and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used until the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by expressing it through linen, and filtering.

The plan of preparing tinctures by percolation has been extensively adopted, and has been found to answer well when skilfully executed. In the present edition of our Pharmacopœia, percolation has been adopted as the rule, maceration being directed in some instances in which it was deemed preferable.

The method of making tinctures by diluting fluidextracts, except in a few special cases, is not to be recommended. The menstruum directed for the fluidextract is most frequently not identical with that used for the tincture, and precipitation of active constituents often ensues when this easy method is employed. Owing to the larger dose of the tinctures, and consequently less degree of concentration, a larger proportion of water can be used in their menstrua than in fluidextracts, and this is a distinct advantage, as tinctures are frequently prescribed in combination with aqueous solutions.

Another mode of exhausting medicines by spirit has been proposed by H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks, and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. For this mode of preparing tinctures Samuel Gale proposed the use of a cylindrical stoneware vessel with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum.

Tinctures prepared by adding alcohol to the expressed juices of plants have been long in use on the continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices.* This method of preparing tinctures has, however, been abandoned by both the U. S. and Br. Pharmacopœias. Preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so, as they contain necessarily not only the soluble active matter of the juice, but also that which, when the juice is expressed, is left in the solid residue of the plant. For further information see *U. S. D.,* 19th ed., p. 1293.

A process for making tinctures from fresh drugs was official in the U. S. P. VIII. It was deleted from the U. S. P. IX, but introduced into the National Formulary under the heading *Tincturæ Medicamentorum Recentium* (see Part III).

Tinctures should be kept in bottles accurately stoppered, in order to prevent evaporation, which might in some instances be attended with serious inconvenience, by increasing their strength beyond the official standard.

Medicines which act in small doses are most conveniently administered in tinctures, as the proportion of alcohol in which they are dissolved is usually insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

Progressive pharmacy demands greater uniformity and simplicity in the processes, and hence in the present U. S. P. practically all of the tinctures have been brought into two classes, 20 and 10 Gm. of drug per 100 cc. The potent tinctures employ 10 Gm. per 100 cc. in order to comply with the recommendations of the Brussels Conference of 1902 for the unification of the strength of Potent Remedies.

A tabulated comparison of the tinctures of the P. G. IV and P. G. V as to sp. gr., extractive percentage and alkaloidal content, is available for those to whom it would be of value in the Yearbook of the *A. Ph. A.*, 1913, p. 84.

TINCTURA ACONITI. U. S., Br.

TINCTURE OF ACONITE Tr. Aconit. [Aconiti tinctura P. I.]

"Tincture of Aconite, administered subcutaneously to guinea pigs, has a minimum lethal dose of not less than 0.00,035 cc. and not more than 0.00,045 cc. for each Gm. of body weight of guinea pig." *U. S.* "Tincture of Aconite contains in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root." *Br.*

Tinctura Aconiti Radicis, *U. S.* 1870; Tincture of Aconite Root; Teinture d'Aconit (Racine), *Fr. Cod.;* Tinctura Aconiti, *P. G.;* Akonittinktur, Eisenhuttinktur, *G.;* Tinctura di aconito, *It.;* Tintura alcoholica de aconito, *Sp.*

"Aconite, in fine powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using a mixture of 7 volumes of alcohol and 3 volumes of water as the menstruum. Adjust the volume of the finished Tincture to conform to the above biological standard.

"Alcohol content, by volume, 61 to 65 per cent." *U. S.*

"Aconite Root, in No. 40 powder, 150 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with seventy-five millilitres of the Alcohol, and produce, by the *percolation process,* one thousand millilitres of a strong tincture. Determine the proportion of ether-soluble alkaloids present in this strong tincture, by evaporating one hundred millilitres to dryness in a shallow porcelain evaporating basin, and proceeding as directed under 'Aconiti Radix.' Dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a tincture of Aconite containing 0.04 gramme of ether-soluble alkaloids in 100 millilitres of the Tincture. Examined by the foregoing process Tincture of Aconite is found to contain in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root. *Limit of error* 0.002 gramme in excess or defect. This Tincture is of approximately the same strength as the Tinctura Aconiti of the International Agreement, and about twice as strong as the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

There is a very material difference in the strength of the tinctures of the U. S. and Br., that of the latter being apparently 50 per cent. stronger than the International Protocol, while the U. S. adheres to the 10 per cent. standard. On the other hand, the difference is probably not so great because the American standard for aconite root is higher than that of the Br.

Assay.—The Br. gives a method for determining the proportion of alkaloids in this tincture (see above) but as pointed out elsewhere (see under *Aconitum*) the chemical assay of this drug or its preparations is of little practical value (see Dohme, *J. A. Ph. A.*, 1921, x, 428) and has been omitted from the U. S. P.

Of the various methods that have been suggested for standardizing aconite by biological experiment only two seem of any practical value.

The first of these—in fact probably the oldest of all biological methods of standardizing—is that suggested by the late Doctor Squibb which is based upon the peculiar effects of aconite on peripheral sensory nerve endings. The principle of the method consists in determining the lowest dilution in which a given sample taken into the mouth of the experimenter produces the first perceptible degree of tingling in the tongue. The method may be carried out as follows: After rinsing the mouth with distilled water 4 cc. (1 fluidrachm) of an aqueous solution, representing one part of aconite *root* to 600 parts of water, is taken into the anterior part of the mouth and held there for one minute and then expelled. If the drug is of standard quantity there is produced in a few minutes a characteristic sensation, too faint to be properly called tingling and yet closely allied to it. If, at the end of fifteen minutes, there is no distinct sensation the drug may be deemed below standard and stronger solutions tested in the same manner. On the other hand, if it produces a sharp, distinct, tingling it is stronger than normal and less concentrated solutions should be tested. It is evident that personal susceptibility must play a considerable part in this method and it is necessary for the experimenter to standardize himself by determining his sensitiveness towards a sample of known potency. Although the method may seem rather crude to the chemist accustomed to the exactitude of physical measurements, Roth has found (*J. A. Ph. A.*, 1913, ii, 705) that it may be made to yield very satisfactory results.

The second method, which has the advantages of eliminating the personal factor and also of allowing the test of several samples simultaneously, is the method which has been adopted by the Pharmacopœia based upon the fatal dose for guinea pigs.

The official directions for this assay process are as follows: "Use guinea pigs weighing from 275 Gm. to 325 Gm. each and in good health. Dilute the Tincture with distilled water to make the dose about 1 cc., and inject into the guinea pig under the skin of the abdomen. The standard dose must kill within six hours at least two of every three guinea pigs injected." *U. S.*

In carrying out the assay it is convenient to make a preliminary test using four guinea-pigs, which are injected respectively with doses of 0.3, 0.4, 0.45 and 0.5 milligramme, of the tincture, per gramme of body weight. The syringe for the injection should be graduated in tenths of a cc., such as the so-called tuberculin syringe. We believe that the use of such syringe is more convenient than first measuring the fluid into another vessel. In making the injection, care should be taken not to penetrate the abdominal wall, as absorption from the peritoneal cavity is so rapid that the results would be very different; the fluid should be injected immediately beneath the skin and outside the abdominal muscles. If in the preliminary series, just mentioned, none of the animals survive the drug is too strong, but if none of them die it is too weak. In either case a second series of preliminary tests should be made using doses either larger or smaller, according to the results of the first series. If, however, some of the animals survive and some die, a second series of tests should be made, using doses of 0.35, 0.38, 0.4, 0.4, 0.42, 0.45. Of these six animals, at least one should survive and at least four die. For literature on this assay see Swanson and Walters (*J. A. Ph. A.*, 1923, xii, 957).

For a paper on Tincture of Aconite, by M. I. Wilbert, see *Proc. A. Ph. A.*, 1902, 348.

There was formerly employed in the United States, and at one time recognized by the N. F., a preparation known as *Fleming's Tincture of Aconite,* which represented 70 per cent. of aconite root.

Uses.—A tincture of aconite thoroughly represents the drug and is the most frequently prescribed preparation for internal use. It is occasionally employed externally as an addition to liniments, but it is not to be recommended for this purpose as toxic symptoms have been reported from its external application.

Swanson and Walters (*loc. cit.*) have shown that tincture of aconite deteriorates rapidly, but states that the addition of acetic acid prevents this change.

Dose, five to fifteen minims (0.3–1 cc.).

Off. Prep.—Dentilinimentum Aconiti Compositum, *N. F.;* Deutilinimentum Aconiti et Iodi Compositum, *N. F.*

TINCTURA ALSTONIÆ. Br.

TINCTURE OF ALSTONIA

"Alstonia, in No. 20 powder, 125 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture represents whatever therapeutic properties alstonia bark may possess. It is used in *malaria.*

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA ARNICÆ FLORUM. Br.

TINCTURE OF ARNICA FLOWERS

Teinture d'Arnica, *Fr. Cod.;* Tinctura Arnicae, *P. G.;* Arnikatinktur, *G.;* Tintura di Arnica, *It.;* Tintura alcoholica de arnica, *Sp.*

The U. S. X has dropped this tincture but a similar preparation has been admitted to the N. F. (see Part III).

"Arnica Flowers, in No. 20 powder, 100 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred *millilitres* of the Alcohol, and complete the *percolation process.*" *Br.*

Either alone, or diluted with water, soap liniment, etc., tincture of arnica is often applied popularly to *bruises, sprains, tumors* and local *rheumatic pains,* under the impression that it has extraordinary healing powers. It probably acts merely as a counter-irritant. On some skins it produces a violent eczematous inflammation.

Dose, one-half to one fluidrachm (2–4 cc.).

TINCTURA ASAFŒTIDÆ. U. S. (Br.)

TINCTURE OF ASAFETIDA Tr. Asafœt.

Tinctura Asafetidæ, *Br.;* Teinture (alcoolé), d'Asafœtida, *Fr. Cod.;* Asanttinktur, Stinkasanttinktur, *G.;* Tinctura alcoholica de asafetida, *Sp.*

"Asafetida, bruised, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using alcohol as the solvent.

"Alcohol content, by volume, 78 to 85 per cent." *U. S.*

"Asafetida, bruised, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Macerate the Asafetida in a closed vessel with *seven hundred and fifty millilitres* of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

This tincture becomes milky on the addition of water, in consequence of the separation of the resin.

Dose, thirty minims to a fluidrachm (2–4 cc.).

Off. Prep.—Mistura Magnesii, Asafœtidæ et Opii, *N. F.*

TINCTURA AURANTII AMARI. U. S. (Br.)

TINCTURE OF BITTER ORANGE PEEL

Tr. Aurant. Amar.

Tinctura Aurantii, *Br.;* Tincture of Orange; Teinture d'Orange amère (Ecorce), *Fr.;* Tinctura Aurantii, *P. G.;* Pomeranzentinktur, Pomeranzenschalentinktur, *G.*

"Bitter Orange Peel, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using a mixture of 3 volumes of alcohol and 2 volumes of water as the menstruum.

"Alcohol content, by volume, 53 to 56 per cent." *U. S.*

"Fresh Bitter-Orange Peel, cut small, 250 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

It is the peel of the Seville orange that is directed in this process, and the outer part only is active. The two tinctures differ because of the fact that the Br. "orange peel" is only of the outer layer, while the U. S. includes also the inner, white, portion of the rind. The U. S. tincture has a greenish-brown color and a bitterish taste, the latter due to the presence of hesperidin from the inner layer of the rind. The Br. tincture of orange more closely resembles the U. S. *Tinctura Aurantii Dulcis* in sensible properties. The tincture of bitter orange peel is employed as a flavoring agent to infusions, decoctions, and mixtures.

Off. Prep.—Syrupus Aromaticus, *Br.;* Syrupus Aurantii, *Br.;* Elixir Aurantii Amari, *N. F.*

TINCTURA AURANTII DULCIS. U. S.

TINCTURE OF SWEET ORANGE PEEL
Tr. Aurant. Dulc.

Alcoolature d'Orange, *Fr. Cod.;* Teinture de Zeste d'Orange douce, *Fr.;* Apfelsinenschalentinktur, *G.*

"Sweet Orange Peel, the outer yellow rind, grated from the fresh fruit, 500 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, macerating the drug in 1000 cc. of alcohol and completing the preparation with alcohol. Use purified cotton as the filtering medium." *U. S.*

This tincture was designed to furnish a highly flavored alcoholic preparation of orange and has no medicinal properties. It is used as a pleasant adjuvant and flavoring agent.

On account of its alcoholic content and its lack of medicinal properties tincture of sweet orange peel is one of the preparations coming under the restrictions of the Volstead Act as regards its manufacture and sale. The volatile oil content has been found to be between 0.5 and 1.0 per cent.

Off. Prep.—Syrupus Aurantii, *U. S.*

TINCTURA BELLADONNÆ. U. S., Br.

TINCTURE OF BELLADONNA LEAVES Tr. Bellad.
[Tinctura Belladonnæ Foliorum, U. S. IX. Belladonnæ tinctura P. I.]

"Tincture of Belladonna yields, from each 100 cc., not less than 0.027 Gm. and not more than 0.033 Gm. of the alkaloids of belladonna leaves." *U. S.* "Tincture of Belladonna contains in 100 millilitres 0.035 *gramme* of the alkaloids of Belladonna Leaves." *Br.*

Tincture of Belladonna; Teinture de feuille de Belladone, *Fr.;* Belladonnatinktur, *G.;* Tintura alcoholica de belladonna, *Sp.*

"Belladonna Leaves, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using diluted alcohol as the menstruum, and adjust the volume of the finished Tincture by the addition of diluted alcohol to make each 100 cc. contain 0.03 Gm. of the alkaloids of belladonna leaves." *U. S.*

"Belladonna Leaves, dried and in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.) sufficient to produce 1000 *millilitres.*

"Moisten the Belladonna Leaves with one hundred millilitres of the Alcohol, and complete the *percolation process.* Determine the proportion of alkaloids contained in the tincture so prepared by the Br. process below." *Br.*

Assay.—"Proceed by Type Process D, taking 100 cc. of Tincture of Belladonna, use chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of belladonna leaves (Proximate Assays).

"Alcohol content, by volume, 44 to 47 per cent." *U. S.*

"Evaporate 100 millilitres in an evaporating basin on a water-bath until it measures about 10 millilitres, add, if necessary, sufficient *alcohol* (90 per cent.) to dissolve any separated substance and transfer to a separator, rinsing the dish with a little *water.* Add 10 millilitres of *water,* 20 millilitres of chloroform, and 2 millilitres of *solution of ammonia.* Shake well and separate the chloroformic layer. Repeat the extraction with two successive portions of 10 millilitres of *chloroform.* Mix the chloroformic solutions, and shake them with 10 millilitres of *N/1 solution of sulphuric acid* diluted with twice its volume of *water.* Separate the chloroformic solution. Repeat the shaking with a further 10 millilitres of the acidified water. Mix the acid solutions, add 20 millilitres of *chloroform* and 4 millilitres of *solution of ammonia.* Shake well, draw off the chloroformic solution into a beaker, and repeat the extraction with two further portions, each of 10 millilitres, of *chloroform.* Allow the mixed chloroformic solutions to evaporate, dry the residue on a water-bath for thirty minutes, dissolve it in 10 millilitres of *N/20 solution of sulphuric acid* and titrate with *N/20 solution of sodium hydroxide,* using *tincture of cochineal* as indicator. Deduct the number of millilitres of alkaline solution required from 10, and multiply the difference by 0.01446; the product will be the weight in grammes of the alkaloids contained in 100 millilitres of the tincture. This quantity should be not less than 0.035 gramme. Should the tincture contain more than this proportion it must be diluted with the necessary quantity of Alcohol (70 per cent.).

"Examined by the foregoing process, Tincture of Belladonna is found to contain in 100 millilitres 0.035 gramme of the alkaloids of Belladonna Leaves. *Limit of error* 0.002 gramme in excess or defect. This Tincture contains seven-tenths of the proportion of alkaloids contained in the Tincture of Belladonna of the British Pharmacopœia, 1898. It may be used when the Tinctura Belladonnæ of the International Agreement is required." *Br.*

In the U. S. P., 1890, the name of this tincture was changed to *Tinctura Belladonnæ Foliorum,* for the sake of greater precision, but the tenth revision has returned to the older name and dropped the unnecessary "Foliorum."

The tincture is an efficient preparation when made from the recently dried leaves and assayed by the official process.

Dose, from five to fifteen minims (0.3–0.9 cc.).

TINCTURA BENZOINI. U. S.

TINCTURE OF BENZOIN Tr. Benz.

Teinture (alcoolé) de Benjoin, *Fr.;* Tinctura Benzoës, *P. G.;* Benzoëtinktur, *G.;* Tintura di benzoino, *It.;* Tintura alcoholica de benjui, *Sp.*

"Benzoin, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using alcohol as the solvent.

"Alcohol content, by volume, 75 to 83 per cent." *U. S.*

A popular toilet preparation—sometimes known as *Lac Virginis* (*Lait virginal, Jungfrausmilch*) is made by mixing rose water, glycerin and tincture of benzoin. Some difficulty occurs in this preparation from the separation of the resin. Hensel (*D. C.,* 1915, 509) states when 3 ounces of water were placed in a four-ounce prescription bottle and one-half drachm of tincture of benzoin was rapidly delivered (five seconds) on the surface of the water, followed by vigorous shaking, he obtained a permanent emulsion which showed no signs of separation after ten days. He found that he could, by the same manipulation, mix as much as 1½ ounces of tincture of benzoin with 12 ounces of water and obtain a permanent emulsion if 13½ ounces of glycerin were immediately added to the mixture. He explains the successful emulsification by the theory that the heat of solution of the mixture lessens the adhesive force of the separated resin, thus separating it into an almost colloidal condition.

Tincture of benzoin possesses the therapeutic properties of that drug but it is rarely prescribed by the medical profession.

Dose, fifteen to thirty minims (0.9–1.8 cc.).

Off. Prep.—Unguentum Picis Compositum, *N. F.*

TINCTURA BENZOINI COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF BENZOIN Tr. Benz. Co.

Tinctura Balsamica, Balsamum Commendatoris, Elixir Traumaticum; Friar's Balsam; Teinture balsamique, *Fr. Cod.;* Baume du Commandeur de Permes, *Fr.;* Persischer Wundbalsam, *G.;* Tintura alcoholica de Benjui, *Sp.*

"Benzoin, in moderately coarse powder, 100 Gm.; Aloe, in moderately coarse powder, 20 Gm.; Storax, 80 Gm.; Tolu, 40 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using alcohol as the solvent.

"Alcohol content, by volume, 74 to 80 per cent." *U. S.*

"Benzoin, in powder, 100 *grammes;* Prepared Storax, 75 *grammes;* Balsam of Tolu, 25 *grammes;* Aloes, 20 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.*

"Macerate the Benzoin, Storax, Balsam of Tolu, and Aloes with eight hundred millilitres of the Alcohol in a closed vessel for two days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

Uses.—Compound tincture of benzoin is chiefly employed both for its antiseptic and protective effect as a local application to minor *wounds, chapped hands* or *nipples, indolent ulcers,* etc. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume du commandeur, Wade's balsam, Balsam de Maltha, Friar's balsam, Jesuit's drops, Turlington's balsam,* etc., which were formerly in great repute, and are still esteemed by the people, as pectorals and vulneraries. The compound tincture of benzoin is precipitated by water. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.

It is occasionally employed internally as a stimulating expectorant in *chronic bronchitis.* More frequently it is used as an inhalant by adding a teaspoonful of the tincture to a pint of hot water and breathing the vapors; this mode of treatment is especially useful in the early stages of *acute bronchitis.* It has also been recommended in *chronic dysentery* with the idea that it would exercise its local action upon the ulcerated surface of the colon, but is of doubtful utility.

Dose, fifteen to sixty minims (0.9–3.75 cc.).

TINCTURA BERBERIDIS. Br.

TINCTURE OF BERBERIS

"Berberis, in No. 60 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.*

"Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.* This tincture is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA BUCHU. Br.

TINCTURE OF BUCHU

Teinture (alcoolé) de Buchu, *Fr. Cod.;* Teinture de Bucco, *Fr.;* Buchutinktur, *G.*

"Buchu Leaves, in No. 20 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has the virtues of buchu leaves.

Dose, from one to two fluidrachms (3.75–7.5 cc.), either simply diluted with water or as an addition to the infusion of the leaves.

TINCTURA CALUMBÆ. U. S., Br.

TINCTURE OF CALUMBA Tr. Calumb.

Tinctura Colombo; Teinture (alcoolé) de Colombo, *Fr. Cod.;* Kolombotinktur, *G.;* Tintura alcoholica de colombo, *Sp.*

"Calumba, in coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, packing the moistened drug moderately and using a mixture of 3 volumes of alcohol and 2 volumes of water as the menstruum.

"Alcohol content, by volume, 53 to 56 per cent." *U. S.*

"Calumba Root, in No. 20 powder, 100 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture was doubled in strength at the U. S. P. (VIII) in order to bring it into the class of 20 per cent. non-potent tinctures. The British tincture, 1914, retains the strength of 10 Gm. of drug in each 100 cc.

Joseph Ince recommended that the tincture be prepared from the root as found in commerce, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*P. J.*, xiv, 491.) No. 20 powder is now directed instead of the No. 50 powder used in older Pharmacopœias.

Tincture of calumba is used as a bitter stomachic.

Dose, of the U. S. tincture one-half to one fluidrachm (1.8–3.75 cc.), of the Br. tincture one to two fluidrachms (3.75–7.5 cc.).

TINCTURA CANNABIS INDICÆ. Br.

TINCTURE OF CANNABIS INDICA

Tinctura Cannabis, *U. S. IX;* Tincture of Cannabis; Tincture of Indian Hemp; Tincture of Hemp; Teinture de Chanvre de l'Inde, *Fr.;* Indischhanftinktur, *G.*

"Extract of Indian Hemp, 50 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve." *Br.*

Tincture of cannabis has been dismissed from the U. S. It can be physiologically standardized by the method described under *Cannabis.*

Dose, five to twenty minims (0.3–1.3 cc.), to be gradually increased until some effects are experienced.

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.;* Mistura Chloroformi et Morphinæ Composita, *N. F.*

TINCTURA CANTHARIDIS. U. S. (Br.)

TINCTURE OF CANTHARIDES Tr. Canthar. [Cantharidis tinctura P. I.]

Tinctura Cantharidini, *Br.;* Tincture of Cantharidin; Tincture of Spanish Flies; Teinture de Cantharide, *Fr. Cod.;* Tinctura Cantharidum, *P. G.;* Spanischfliegentinktur, *G.;* Tinctura di cantaridi, *It.;* Tinctura alcoholica de cantaridas, *Sp.*

"Cantharides, in fine powder, 100 Gm.; Glacial Acetic Acid, 50 cc.; Alcohol, a sufficient quantity to make 1000 cc. Moisten the cantharides with a mixture of the glacial acetic acid and 50 cc. of alcohol. Transfer it to a covered percolator and allow to macerate for twenty-four hours, then percolate slowly, using alcohol as the menstruum, until the Tincture measures 1000 cc.

"Alcohol content, by volume, 82 to 87 per cent." *U. S.*

"Cantharidin, 0.1 *gramme;* Chloroform, 10.0 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000.0 *millilitres.* Dissolve the Cantharidin in the Chloroform, and add sufficient of the Alcohol to produce the required volume. This tincture contains approximately one-seventh of the proportion of Cantharidin contained in the Tinctura Cantharidis of the International Agreement; it contains approximately the same proportion of Cantharidin as the Tinctura Cantharidis of the British Pharmacopœia, 1898." *Br.*

This is a very difficult preparation to make in that cantharides is not easily extracted by any solvent suitable for making a tincture. The U. S. IX prepared it by extraction with boiling alcohol, using a reflux condenser to avoid loss of the solvent. Scoville (*J. A. Ph. A.*, 1917, vi, 798) found that it was impossible to exhaust cantharides with alcohol because of the slight solubility of cantharidin in that menstruum. He reported the results of extraction by means of a Soxhlet apparatus with a menstruum of 150 cc. of acetic ether and 5 cc. of glacial acetic acid for 100 Gm. of drug, the extraction continuing until a few drops yielded no residue on spontaneous evaporation. Twelve to eighteen hours were required in most cases, depending on the fineness of the drug. After adjusting the volume of extract to 150 cc., alcohol was added to make 1000 cc. and after 24 hours it was filtered. The finished tincture represented 10 per cent. of the drug in an alcoholic menstruum containing 15 per cent. acetic ether and 0.5 per cent. acetic acid, by volume. Three specimens assayed respectively 83 per cent., 93 per cent., and 95 per cent. of the theoretical strength. He concluded that the drug should be either slowly percolated with 10 volumes of acetic acid and 90 volumes of alcohol, or should be extracted with ethyl acetate and acetic acid as outlined above. The British tincture, 1914, is made by dissolving the blistering principle, cantharidin, in chloroform and alcohol. It is about the strength of the tincture of the Br. Pharm., 1898. It is decidedly weaker than the U. S. preparation.

Tincture of cantharides is frequently used in mixtures of castor oil and alcohol in the so-called hair tonics, and when made with diluted alcohol turbidity results. The official tincture is double the strength of that of the U. S. P. 1890 and is now in conformity with the provisions of the International Protocol. It is the most convenient form for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) If made with diluted alcohol, when long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration.

Dose, of the U. S. tincture, one to three minims (0.06–0.2 cc.); of the Br., two to five minims (0.12–0.3 cc.).

UNIVERSITY OF ILLINOIS LIBRARY-CHEMISTRY

TINCTURA CAPSICI. U. S., Br.

TINCTURE OF CAPSICUM Tr. Capsic.

Tincture of Cayenne Pepper; Teinture de Piment des Jardins, *Fr.;* Tinctura capsici, *P. G.;* Spanischpfeffertinktur, *G.*

"Capsicum, in moderately coarse powder, 100 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using a mixture of 95 volumes of alcohol and 5 volumes of water as the menstruum.

"Tincture of Capsicum should meet the requirements of the following test: Mix 10 cc. of the Tincture with 40 cc. of alcohol in a stoppered flask, and dilute 0.1 cc. of the clear liquid with 140 cc. of distilled water containing 10 per cent. of sucrose. Five cc. of this dilution swallowed at one time will produce a distinct sensation of pungency in the mouth and throat of at least two out of three individuals.

"Alcohol content, by volume, 84 to 88 per cent." *U. S.*

"Capsicum, in No. 20 powder, 50 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The U. S. P. tincture is double the strength of the British. The alcoholic strength of the menstruum is of unusual proportions, 19 volumes of alcohol to 1 volume of water, the reason for this is that, on account of oleoresinous constituents of capsicum, alcohol is required and on account of a small quantity of a constituent soluble in water and insoluble in alcohol a little water must be added to the menstruum to prevent cloudiness. It is used in atonic conditions of the stomach, especially in *alcoholic gastritis.* It may also be used locally in various sluggish conditions of the throat and for the various purposes for which red pepper is applicable. (See *Capsicum.*) Applied by means of camel's-hair pencil to the *relaxed uvula,* it sometimes produces contraction and relieves prolapsus of that part.

Dose, of the U. S. tincture, five to ten minims (0.3–0.6 cc.); of the Br. preparation, ten to twenty minims (0.6–1.3 cc.).

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.;* Mistura Chloroformi et Morphinæ Composita, *N. F.;* Mistura Opii et Chloroformi Composita, *N. F.;* Mistura Opii et Rhei Composita, *N. F.*

TINCTURA CARDAMOMI. U. S.

TINCTURE OF CARDAMOM Tr. Cardam.

Teinture de Cardamome, *Fr.;* Kardamomentinktur, *G.*

"Cardamom Seed, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using diluted alcohol as the menstruum.

"Alcohol content, by volume, 44 to 46 per cent." *U. S.*

The strength of this tincture was doubled in the U. S. P. (VIII) in order to bring it into the 20 per cent. class; it is an agreeable, not very strong, aromatic, and may be advantageously added to tonic and purgative infusions.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA CARDAMOMI COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF CARDAMOM

Tr. Cardam. Co.

Teinture de Cardamome composée, *Fr.;* Zusammengesetzte Kardamomentinktur, *G.*

"Cardamom Seed, in moderately coarse powder, 20 Gm.; Cinnamon, in fine powder, 25 Gm.; Caraway, in moderately coarse powder, 12 Gm.; Cochineal, in fine powder, 5 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, macerating the mixed powders in 750 cc. of a mixture of 50 cc. of glycerin and 950 cc. of diluted alcohol, and completing the preparation by using first the remainder of the mixture prepared as directed above, and then diluted alcohol.

"Alcohol content, by volume, 45 to 47 per cent." *U. S.*

"Cardamom Seeds, in No. 20 powder, 14 *grammes;* Caraway Fruit, in No. 20 powder, 14 *grammes;* Cinnamon Bark, in No. 20 powder, 28 *grammes;* Cochineal, in No. 20 powder, 7 *grammes;* Glycerin, 100 *millilitres;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the mixed powders with fifty millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty *millilitres* of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." *Br.*

This is a very agreeable aromatic tincture, occasionally used as a carminative, but more frequently as an addition to mixtures, infusions, etc., which it renders pleasant to the taste and acceptable to the stomach. It is one of the most highly prized vehicles, not merely because of its pleasant flavor, but also on account of its beautiful color. The substitution of glycerin in the U. S. formula of 1880 for the honey formerly used was an improvement, as it increases the stability of the preparation.

This is one of the preparations which, on account of its attractive flavor and low medicinal value, is included under the restrictive provisions of the Volstead Act.

Dose, one to two fluidrachms (3.75–7.5 cc.).

TINCTURA CASCARILLÆ. Br.

TINCTURE OF CASCARILLA

Teinture de Cascarille, *Fr.;* Kaskarilltinktur, *G.*

"Cascarilla, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred and fifty *millilitres* of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has the properties of cascarilla, but is seldom, if ever, used in this country.

Dose, from thirty minims to two fluidrachms (1.8–7.5 cc.).

TINCTURA CHIRATÆ. Br.

TINCTURE OF CHIRETTA

Tincture of Chirata; Teinture de Chirette, *Fr.;* Chirettatinktur, *G.*

"Chiretta, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is used as a bitter tonic. Although no longer recognized by the U. S. P., it is still prescribed in this country. The tincture of the U. S. 1890 was of twenty per cent. strength.

Dose, from one to two fluidrachms (3.75–7.5 cc.), three or four times a day.

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITA. Br.

COMPOUND TINCTURE OF CHLOROFORM AND MORPHINE

"Chloroform, 75 *millilitres;* Morphine Hydrochloride, 10 *grammes;* Diluted Hydrocyanic Acid, 50 *millilitres;* Tincture of Capsicum, 25 *millilitres;* Tincture of Indian Hemp, 100 *millilitres;* Oil of Peppermint, 2 *millilitres;* Glycerin, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Mix the Chloroform, Tincture of Capsicum, Tincture of Indian Hemp, Oil of Peppermint, and Glycerin, with four hundred and fifty *millilitres* of the Alcohol, and dissolve the Morphine Hydrochloride in the mixture; add the Diluted Hydrocyanic Acid, and sufficient of the Alcohol to produce the required volume. This Compound Tincture contains in 1 millilitre 7.5 centimils of Chloroform, 1 centigram of Morphine Hydrochloride, and 5 centimils of Diluted Hydrocyanic Acid; it contains in 10 minims ¾ minim of Chloroform, 1/11 grain of Morphine Hydrochloride, and ½ minim of Diluted Hydrocyanic Acid." *Br.*

This is the official substitute for *chlorodyne,* the well-known British nostrum. It does not differ from the process of the Br. Pharm. 1898, except that the oil of peppermint was increased from 1.5 cc. to 2 cc. It is much stronger than the *Mistura Opii et Chloroformi Composita* of the N. F. (see Part III).

Dose, from five to fifteen minims (0.3–0.9 cc.).

TINCTURA CINCHONÆ. U. S., Br.

TINCTURE OF CINCHONA Tr. Cinch.

"Tincture of Cinchona yields, from each 100 cc., not less than 0.8 Gm. and not more than 1 Gm. of the alkaloids of cinchona." *U. S.* "Tincture of Cinchona contains in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark." *Br.*

Tincture of Peruvian Bark; Teinture de Quinquina Rouge, *Fr.;* Tinctura Chinæ, *P. G.;* Chinatinktur, *G.;* Tintura di china, *It.;* Tintura alcoholica de Quina, *Sp.*

"Cinchona, in moderately coarse powder, 200 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using as the first menstruum a mixture of 75 cc. of glycerin, 675 cc. of alcohol, and 250 cc. of water, and completing the percolation with a mixture of 2 volumes of alcohol and 1 volume of water. Adjust the volume of the finished Tincture to make each 100 cc. contain 0.9 Gm. of the alkaloids of cinchona.

"Alcohol content, by volume, 60 to 64 per cent." *U. S.*

"Red Cinchona Bark, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with two hundred *millilitres* of the Alcohol; set aside for seven days in a closed vessel; percolate with more of the Alcohol, until seven hundred *millilitres* of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter." *Br.*

The U. S. formula is based on the suggestion of A. B. Taylor to include glycerin in the menstruum. This yields a fairly stable preparation in contrast to the unsatisfactory character of the tinctures made by various other processes.

Assay.—"Proceed by Type Process C, taking 25 cc. of Tincture of Cinchona to which is added 5 cc. of diluted hydrochloric acid before evaporation, use 200 cc. of ether-chloroform mixture, and decant an aliquot portion of 160 cc. of the ethereal solution representing 20 cc. of Tincture. Use chloroform for the final extraction and determine the alkaloids gravimetrically (Proximate Assays)." *U. S.*

"Take ten millilitres of the strong tincture so prepared, and determine the proportion of alkaloids contained in it by the process described under 'Extractum Cinchonæ Liquidum.' Add to the bulk of the strong tincture such a quantity of the Alcohol that 100 millilitres of the resulting Tincture contain 1 gramme of the alkaloids of Red Cinchona Bark. Examined by the process described under 'Extractum Cinchonæ Liquidum' Tincture of Cinchona is found to contain in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark. *Limit of error* 0.05 gramme in excess or defect." *Br.*

Tincture of cinchona is rarely employed, but may be used as a bitter tonic. As an antiperiodic it has been entirely superseded by the salts of quinine.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Tinctura Cinchonæ Composita, *Br.*

TINCTURA CINCHONÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF CINCHONA Tr. Cinch. Co.

"Compound Tincture of Cinchona yields, from each 100 cc., not less than 0.4 Gm. and not more than 0.5 Gm. of the alkaloids of cinchona." *U. S.* "Compound Tincture of Cinchona contains in 100 millilitres 0.5 gramme of the alkaloids of Red Cinchona Bark." *Br.*

Compound Tincture of Peruvian Bark; Huxham's Tincture of Bark; Whytt's Tincture; Elixir Roborans Whytii; Teinture de Quinquina Composée, Elixir Febrifuge de Huxham, *Fr.;* Tintura Chian Composita, *P. G.;* Zusammengesetzte Chinatinktur, *G.;* Tintura Alcoholica de Cortezade Naranja Compuesta, *Sp.*

"Cinchona, in moderately coarse powder, 100 Gm.; Bitter Orange Peel, in moderately coarse powder, 80 Gm.; Serpentaria, in fine powder, 20 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using as the first menstruum a mixture of 75 cc. of glycerin, 675 cc. of alcohol, and 250 cc. of water, and complete the percolation with a mixture of 2 volumes of alcohol and 1 volume of water. Adjust the volume of the finished Tincture to make each 100 cc. contain 0.45 Gm. of the alkaloids of cinchona.

"Alcohol content, by volume, 58 to 64 per cent.

"**Assay.**—Proceed by Type Process C, taking 50 cc. of Compound Tincture of Cinchona, to which is added 5 cc. of diluted hydrochloric acid before evaporation, use 200 cc. of ether-chloroform mixture, and decant an aliquot portion of 160 cc., representing 40 cc. of the Tincture. Use chloroform for the final extraction and determine the alkaloids gravimetrically (Proximate Assays)." *U. S.*

"Dried Bitter-Orange Peel, bruised, 50 *grammes;* Serpentary Rhizome, in No. 40 powder, 25 *grammes;* Cochineal, in powder, 3 *grammes;* Tincture of Cinchona, 500 *millilitres;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Mix the solid ingredients with five hundred millilitres of the Alcohol; set aside in a closed vessel for seven days, shaking frequently; strain, and then press; mix the two liquids thus obtained; add the Tincture of Cinchona, and sufficient of the Alcohol to produce the required volume; set aside for twenty-four hours; filter. Examined by the process described under 'Extractum Cinchonæ Liquidum' Compound Tincture of Cinchona is found to contain in 100 millilitres 0.5 gramme of the alkaloids of Red Cinchona Bark. *Limit of error* 0.05 gramme in excess or defect." *Br.*

This is the preparation commonly known by the name of *Huxham's tincture of bark.* The use of glycerin is an improvement, precipitation being thus largely prevented as in the case of the simple tincture of cinchona. The process for the British tincture presents some novel features. Half of the quantity of the tincture is first made from four of the ingredients; this is then mixed with an equal bulk of tincture of cinchona. The reason for this was probably to avoid assaying a mixed product during the process; but the final test has to deal with the finished tincture, and the utility of the whole method is doubtful.

As this tincture is directed to be made by percolating definite amounts of red cinchona, bitter orange and serpentaria with alcohol, glycerin and water, but assayed only for cinchona alkaloids it is obvious that the adjustment may reduce the proportion of bitter orange, serpentaria and glycerin materially and prevent uniformity in different lots of compound tincture. Nitardy (*J. A. Ph. A.,* 1919, viii, 114) suggests making the tincture in two portions, "the first representing one-half of the volume of the finished tincture and containing all of the bitter orange peel and serpentaria, the other representing the cinchona adjusted to proper strength (double that of the compound tincture) and these mixed in equal volumes, would produce a product that would be more nearly uniform" than the present official method.

Compound tincture of cinchona is an excellent bitter tonic, useful for its local effect on the stomach but too feeble in the principles of cinchona to serve when the systemic action of the drug is required.

Dose, one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Gargarisma Guaiaci Composita, *N. F.*

TINCTURA CINNAMOMI. Br.

TINCTURE OF CINNAMON Tr. Cinnam.

Teinture (alcoolé) de Cannelle, *Fr. Cod.;* Tinctura Cinnamomi, *P. G.;* Zimmttinktur, *G.;* Tintura alcoholica de canela, *Sp.*

"Cinnamon Bark, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has, unfortunately, been dismissed from the U. S. but is recognized by the N. F. (see Part III). By long keeping it is prone to gelatinize and become unfit for use. It is an agreeable flavoring to other tinctures and because of its astringent powers is especially used in *diarrhea* mixtures.

Dose, one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Elixir Taraxaci Compositum, *N. F.;* Mistura Rhei Alkalina, *N. F.*

TINCTURA COCCI. Br.

TINCTURE OF COCHINEAL

Teinture (alcoolé) de Cochenille, *Fr. Cod.;* Cochenilletinktur, *G.*

"Cochineal, in powder, 100 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This is valued chiefly for imparting color to liquid preparations; four or five per cent. of this tincture will give a deep red color. (See *Coccus.*)

Dose, from five to fifteen minims (0.3–1 cc.).

TINCTURA COLCHICI. U. S., Br.

TINCTURE OF COLCHICUM Tr. Colch. Sem. [Tinctura Colchici Seminis U. S. IX, Colchici tinctura, P. I.]

"Tincture of Colchicum yields, from each 100 cc. not less than 0.036 Gm. and not more than 0.044 Gm. of colchicine." *U. S.*

Tincture of Colchicum Seed; Teinture de Colchique, *Fr. Cod.;* Tinctura Colchici, *P. G.;* Zeitlosentinktur, *G.;* Tintura alcoholica de colquico, *Sp.*

"Colchicum Seed, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using a mixture of 3 volumes of alcohol and 2 volumes of water as the menstruum, and adjust the volume of the finished Tincture to make each 100 cc. contain 0.04 Gm. of colchicine.

"Alcohol content, by volume, 54 to 57 per cent." *U. S.*

"Colchicum Seeds, in No. 30 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.* This Tincture is of approximately the same strength as the Tinctura Colchici of the International Agreement, and is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay.—"Evaporate 150 cc. of Tincture of Colchicum on a water bath to about 15 cc., cool, and dissolve the residue in sufficient distilled water to make 290 cc. Add 10 cc. of solution of lead subacetate, and agitate the mixture frequently during one hour. Filter off 200 cc. and proceed as directed under *Golchici Semen,* beginning with the word 'Add.'" *U. S.*

This is another tincture in which it is difficult to extract the drug satisfactorily with any appropriate menstruum. Some of the processes formerly recommended included the use of a hot menstruum. This is unsatisfactory. The present official method has been found to give an efficient preparation when carefully followed.

This tincture possesses the properties of colchicum, and may be given whenever that medicine is indicated, but the fluidextract, containing less alcohol, is generally preferred.

Dose, from ten to thirty minims (0.6–1.8 cc.), to be repeated with caution.

TINCTURA CUBEBÆ. Br.

TINCTURE OF CUBEBS

Teinture de Cubèbe, *Fr. Cod.;* Kubebentinktur, *G.*

"Cubebs, in No. 20 powder, 200 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The U. S. P. has not recognized this tincture for many years, but it is official in the N. F. (see Part III). While this tincture represents the therapeutic virtue of cubeb, it is an inelegant form of administering that drug.

Dose, one to two fluidrachms (3.75–7.5 cc.).

TINCTURA DATURÆ SEMINUM. Br.

TINCTURE OF DATURA SEEDS

"Datura Seeds, in No. 20 powder, 250 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the bruised Datura Seeds with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture well represents the activities of datura seeds.

Dose, five to fifteen minims (0.3–0.9 cc.).

TINCTURA DIGITALIS. U. S., Br.

TINCTURE OF DIGITALIS Tr. Digit. [Digitalis tinctura P. I.]

"Tincture of Digitalis, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.0055 cc. and not more than 0.0065 cc., equivalent to not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each Gm. of body weight of frog." *U. S.*

Tincture of Foxglove; Teinture de Digitale, *Fr. Cod.;* Tinctura Digitalis, *P. G.;* Fingerhuttinktur, *G.;* Tintura di digitale, *It.;* Tintura alcoholica de digital, *Sp.*

"Digitalis, in fine powder, 100 Gm.; to make about 1000 cc. Pack the Digitalis firmly in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids, and percolate slowly with purified petroleum benzin until a few drops of the percolate evaporated from filter paper leave no greasy stain. Reject the benzin percolate. Remove the drug from the percolator and expose it to the air until the odor of benzin is no longer noticeable. Prepare from this a tincture by Type Process P as modified for assayed tinctures, using a mixture of 4 volumes of alcohol and 1 volume of water as the menstruum. Adjust the volume of the finished Tincture to conform to the above biological standard.

"Alcohol content, by volume, 67 to 72 per cent." *U. S.*

"Digitalis Leaves, in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.* This tincture is of approximately the same strength as the Tinctura Digitalis of the International Agreement, and is of four-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay.—"Use healthy frogs of the same species (*Rana pipiens* Schreber) and of a fairly uniform size (20 to 30 Gm.).

"*Storage.*—Before use, the frogs should be stored in constant temperature tanks kept in a cool room, preferably where the temperature does not rise above 15° C. The bottom of the tanks should be covered with running water. The day before the frogs are to be used, a sufficient number should be taken from the storage tanks and placed in a tank, the temperature of which is approximately 20° C. One hour before the assay, they are weighed to within 0.5 Gm. and placed in wire cages or containers in a tank containing water to the depth of about 1 cm. (½ inch), the water being kept at a uniform temperature of 20° C. during the assay.

"*Dosage.*—The doses of the tincture to be given the frogs are calculated according to the weights of the frogs and are injected into the ventral lymph sac by means of a pipette or glass syringe which is graduated in hundredths of a cubic centimeter. The injection is made into the lymph sac through the floor of the mouth, care being taken not to puncture the skin. The amount of fluid to be injected into the different frogs should be as uniform in quantity as possible, approximately 0.015 cc. for each Gm. of body weight of frog. In case the alcohol content in any preparation after dilution is higher than 20 per cent., the preparation may be subjected to careful evaporation and subsequent addition of distilled water until the original volume is restored and the alcohol content is not above the per cent. named. The animal is replaced in its cage in the tank after injection, the temperature being maintained at 20° C. About fifty-eight minutes from the time of injection, each frog is pithed, the heart is exposed, and its condition examined. For the correct end reaction, at the expiration of one hour from the time of injection, the ventricle must be in systolic standstill, while the auricles are widely dilated. Following mechanical stimulations, feeble contractions may occur in the auricles and localized contractions in the ventricle, but no general contraction is allowable. If, when the lymph sac is opened to expose the heart, any of the injected drug is found unabsorbed, the animal must be discarded and not considered in the results obtained." *U. S.*

For details of carrying out this assay and description of other methods of standardization see under *Digitalis.*

It is well established that tincture of digitalis is more liable to deterioration than well kept leaves. According to the investigations of Pittenger (*J. A. Ph. A.*, 1918, vii, 1031), the loss of strength may be anywhere from nothing to 12 per cent. a month, the average being about 20 to 30 per cent. a year. The factors which influence the rapidity of deterioration he could not discover; it did not seem to depend on the strength of alcohol employed in its extraction.

According to Focke, light accelerates the change. (See also Eberhardt and Eldred, *J. A. Ph. A.*, 1914, iii, p. 38.)

Uses.—Tincture of digitalis probably represents the crude drug better than any other official preparation. The beginning dose is ordinarily from five to fifteen minims (0.3–0.9 cc.) three or four times a day, increased cautiously as circumstances demand. Very much larger single doses may be employed, thus as high as a fluidrachm may occasionally be given at a dose if not repeated.

It should be remembered that, as with most of the tinctures, one minim is equivalent to about two drops.

Dose, from five to thirty minims (0.3–1.8 cc.).

TINCTURA ERGOTÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF ERGOT

Tinctura Secalis Cornuti Ammoniata; Teinture Ammoniacale de Seigle Ergoté, *Fr.;* Ammoniakalische Mutterkorntinktur, *G.*

"Ergot, in No. 20 powder, 250 *grammes;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Mix the Solution of Ammonia with nine hundred millilitres of the Alcohol; moisten the powder with one hundred millilitres of this mixture, and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add sufficient of the Alcohol to produce the required volume; set aside for twenty-four hours; filter." *Br.*

This is a new official tincture of the Br. Ph., 1898; it differs from the tincture recommended by the British Pharmaceutical Conference in the use of solution of ammonia in place of aromatic spirit of ammonia. Its value is very questionable as the alkalies appear to destroy the activity of ergot.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA FERRI CHLORIDI.
U. S., Br.

TINCTURE OF FERRIC CHLORIDE Tr. Ferr. Chlor.
[Tincture of Iron]

"A hydro-alcoholic solution containing about 13 per cent. of ferric chloride [$FeCl_3$], corresponding to not less than 4.48 per cent. of Fe." *U. S.*

Tinctura Ferri Perchloridi, *Br.;* Tincture of Chloride of Iron; Tinctura Ferri Muriatis; Tincture of Perchloride of Iron; Tinctura of Muriate of Iron; Tinctura Ferri Sesquichloridi; Teinture de Perchlorure de fer, *Fr.;* Tinctura Ferri Chlorati, *P. G.;* Eisenchloridtinktur, *G.*

"Solution of Ferric Chloride, 350 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the solution with enough alcohol to make 1000 cc." *U. S.*

"Strong Solution of Ferric Chloride, 250 *millilitres;* Alcohol (90 per cent.), 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix." *Br.*

This is one of many official preparations in which there has been great variation in the methods of preparing it during the century of its official recognition. It was originally made by weight instead of volume. The free acidity causes the development of a small proportion of an ester which gives a peculiar flavor to the tincture and probably modifies in some degree its influence on the system. For this reason it is preferable to keep the tincture for some time before dispensing.

Description and Physical Properties.—"A bright, amber-colored liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction. Specific gravity: about 1.00 at 25° C. The Tincture responds to the reactions for ferric iron, and for chlorides. After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide T.S. (presence of some *ferrous salt,* due to reduction). Mix 3 cc. of the Tincture with 10 cc. of ferrous sulphate T.S., and carefully superimpose this mixture upon 3 cc. of sulphuric acid contained in a test tube: the zone of contact does not assume a brown or reddish-brown color (*nitrate*).

"**Assay.**—Place about 5 cc. of Tincture of Ferric Chloride in a tared weighing bottle, weigh accurately, transfer it to a tall beaker, and evaporate to dryness on a water bath. Add to the residue 2 cc. of hydrochloric acid and 5 cc. of solution of hydrogen dioxide, and again evaporate to dryness. Dissolve this residue in 3 cc. of hydrochloric acid, and transfer to a 250 cc. glass-stoppered flask by means of 25 cc. of distilled water. Add about 1 Gm. of potassium iodide, and allow the mixture to stand for thirty minutes at a temperature of 40° C., the flask being securely stoppered while it is being warmed. Cool the solution, add 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

"Preserve in amber-colored, glass-stoppered bottles, protected from light." *U. S.*

The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and mucilage of acacia, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.

Bestucheff's tincture, which is much used in Europe, is simply a solution of ferric chloride in a mixture of one measure of ether and three measures of alcohol. (See *Tinctura Ferri Chloridi Etherea,* N. F.)

Uses.—Tincture of chloride of iron has in the past been attributed with curative properties verging on the mystical. Thus it has been supposed to exercise a specific action in *erysipelas, diphtheria,* and other infectious diseases. Its value in these states, however, is, to say the least, questionable. In *Bright's disease* it has been used not only for its chalybeate effect but with the idea that its astringent action would lessen the quantity of albumin in the urine. As it is an active coagulant of albumin, however, it cannot exist in the blood and therefore can never reach the kidney unchanged; any beneficial effect which may follow its employment in diseases of the kidney is of the same nature as that which is produced by other preparations of iron, namely, an enrichment of the hemoglobin content of the blood. In *anemias* it acts as a chalybeate, but is inferior to many other salts of iron. In the first place a dose of fifteen minims represents only approximately 0.7 grain of iron. In the second place, because of its high astringency and local irritant effect it cannot be administered in large quantities without producing disturbances in the stomach. Locally it is valuable as an astringent in *hemorrhages* and passive congestions of the mucous membrane. Mixed with equal parts of glycerin and water it may be applied by means of a swab with benefit in various types of *pharyngitis.* Its use as a gargle is not to be recommended as its acidity makes it injurious to the teeth.

Dose, five to thirty minims (0.3–1.8 cc.), which may be gradually increased.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, *U. S.;* Elixir Chloridorum, *N. F.*

TINCTURA GAMBIR COMPOSITA. U. S. (Br.)

COMPOUND TINCTURE OF GAMBIR Tr. Gambir Co. [Compound Tincture of Pale Catechu]

Tinctura Catechu, *Br.;* Tincture of Catechu; Teinture de Cachou, *Fr. Cod.;* Tinctura Catechu, *P. G.;* Katechutinktur, *G.*

"Gambir, in moderately coarse powder, 50 Gm.; Cinnamon, in fine powder, 25 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using diluted alcohol as the solvent.

"Alcohol content, by volume, 44 to 47 per cent." *U. S.*

"Catechu, in powder, 200 *grammes;* Cinnamon Bark, bruised, 50 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The British tincture (1898) was increased to 20 per cent. in the proportion of catechu, and is now four times the strength of the U. S. tincture.

This is a grateful astringent tincture, useful in all cases to which gambir is applicable and in which small quantities of spirit are not objectionable. It is especially employed in the treatment of *diarrhea.* It sometimes gelatinizes when kept, and becomes unfit for use.

Dose, of the U. S. tincture of gambir, two to four fluidrachms (7.5–15.0 cc.); of the British tincture of catechu, one-half to two fluidrachms (1.8–7.5 cc.).

Off. Prep.—Tinctura Opii et Gambir Composita, *N. F.*

TINCTURA GELSEMII. Br.

TINCTURE OF GELSEMIUM Tr. Gelsem.

Teinture de Gelsemium, *Fr.;* Gelsemiumtinktur, *G.*

Gelsemium was dropped at the tenth revision of the U. S. but both it and the tincture are recognized by the N. F.

"Gelsemium Root, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

For Farr and Wright's method of estimating this tincture, see *C. D.,* 1892, 263.

Dose, from five to twenty minims (0.3–1.3 cc.).

TINCTURA GENTIANÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF GENTIAN
Tr. Gentian. Co.

Teinture de Gentiane Composée, *Fr.;* Zusammengesetzte Enziantinktur, *G.*

"Gentian, in moderately coarse powder, 100 Gm.; Bitter Orange Peel, in moderately coarse powder, 40 Gm.; Cardamom Seed, in moderately coarse powder, 10 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, packing the mixed drugs moderately, using as the first menstruum a mixture of 100 cc. of glycerin, 500 cc. of alcohol and 400 cc. of water, and completing the percolation with diluted alcohol.

"Alcohol content, by volume, 43 to 47 per cent." *U. S.*

"Gentian Root, cut small and bruised, 100.0 *grammes;* Dried Bitter-Orange Peel, bruised, 37.5 *grammes;* Cardamom Seeds, in powder, 12.5 *grammes;* Alcohol (45 per cent.), 1000.0 *millilitres.* Prepare by the *maceration process.*" *Br.*

There has always been difficulty from precipitation in this tincture; glycerin has been added to the menstruum to overcome this annoyance, but it is only partially successful.

This is an elegant bitter, much used in *dyspepsia,* and as an addition to tonic mixtures in debilitated states of the digestive organs. There is, however, much danger of its abuse by alcoholics, especially in chronic cases.

Dose, one to two fluidrachms (3.75–7.5 cc.).

TINCTURA GUAIACI AMMONIATA. Br.

AMMONIATED TINCTURE OF GUAIAC
Tr. Guaiac. Ammon.

Ammoniated Tincture of Guaiacum; Tinctura Guaiaci Composita; Teinture de Gaiac ammoniacale, *Fr.;* Ammoniakalische Guajaktinktur, *G.*

"Guaiacum Resin, in powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Strong Solution of Ammonia, 75 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Mix the Strong Solution of Ammonia with seven hundred millilitres of the Alcohol; add the Guaiacum Resin; set aside in a closed vessel for forty-eight hours, shaking frequently; filter; dissolve the Oil of Lemon and Oil of Nutmeg in the filtrate, and pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

A similar preparation is recognized by the N. F.

The British Pharmacopœia, 1898, improved the process for this tincture by abandoning the distilled aromatic spirit of ammonia, used as a menstruum by the former British authority, and substituting alcohol containing solution of ammonia and volatile oils, the proportion of oil of lemon having been reduced 60 per cent.

This tincture is celebrated in the treatment of *chronic rheumatism,* and is frequently also used in *amenorrhea.* It is precipitated by water, and should be administered emulsified with gum, so that the guaiac may be held in suspension.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

TINCTURA HAMAMELIDIS. Br.

TINCTURE OF HAMAMELIS

Teinture (alcoolé) de Hàmamélis, *Fr.;* Hamamelistinktur, *G.;* Tintura alcoholica de hamamelis, *Sp.*

"Hamamelis Bark, in No. 20 powder, 100 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

Dose, from thirty to sixty minims (1.8–3.75 cc.).

TINCTURA HYDRASTIS. Br.

TINCTURE OF HYDRASTIS Tr. Hydrast.
[Tincture of Golden Seal]

Teinture (alcoolé) de Hydrastis, *Fr.;* Hydrastistinktur, *G.;* Tintura alcoholica de hidrastis, *Sp.*

"Liquid Extract of Hydrastis, 100 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Mix." *Br.*

This tincture was dropped at the tenth revision of the U. S. because it was felt that hydrastis was so feeble that the effects of the tincture were due chiefly to its alcohol. The former U. S. tincture was twice the strength of the Br. It was made as follows: "Hydrastis, in No. 60 powder, *two hundred grammes* to make about *one thousand mils.* Prepare a Tincture by Type Process P, as modified for assayed tinctures, using a mixture of *two volumes* of alcohol and *one volume* of water as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.4 Gm. of the ether-soluble alkaloids of hydrastis." *U. S. IX.*

This tincture is too feeble to be of any real therapeutic value.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

TINCTURA HYOSCYAMI. U. S., Br.

TINCTURE OF HYOSCYAMUS Tr. Hyosc. [Tincture of Henbane Hyoscyami tinctura P. I.]

"Tincture of Hyoscyamus yields, from each 100 cc., not less than 0.0055 Gm. and not more than 0.0075 Gm. of the alkaloids of hyoscyamus." *U. S.*

Teinture de Jusquiame, *Fr.;* Bilsenkrauttinktur, *G.;* Tintura alcoholica de beleno, *Sp.*

"Hyoscyamus, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using diluted alcohol as the menstruum. Adjust the volume of the finished Tincture to make each 100 cc. contain 0.0065 Gm. of the alkaloids of hyoscyamus. Alcohol content, by volume, 44 to 46 per cent.

"**Assay.**—Proceed by Type Process D, taking 250 cc. of Tincture of Hyoscyamus, evaporate to about 25 cc., use chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of hyoscyamus (Proximate Assays)." *U. S.*

"Hyoscyamus Leaves, in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture possesses the activities of hyoscyamus.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA IODI. U. S. (Br.)

TINCTURE OF IODINE Tr. Iodi.

"An alcoholic solution of iodine and potassium iodide containing, in each 100 cc., not less than 6.5 Gm. and not more than 7.5 Gm. of I, and not less than 4.5 Gm. and not more than 5.5 Gm. of KI." *U. S.*

Tinctura Iodi Mitis, *Br.;* Weak Tincture of Iodine; **Tinctura Iodi Fortis,** *Br.;* Strong Tincture of Iodine; Tinctura Iodinii, *U. S.*, 1870; Teinture d'iode, *Fr. Cod.;* Tinctura Jodi, *P. G.;* Jodtinktur, *G.;* Solucion alcoholica de yodo, *Sp.*

"Iodine, 70 Gm.; Potassium Iodide, 50 Gm.; Distilled Water, 50 cc.; Alcohol, a sufficient quantity to make 1000 cc. Dissolve the potassium iodide in the distilled water contained in a bottle graduated to 1000 cc., add the iodine, and agitate the mixture until solution is effected. Then add sufficient alcohol to make 1000 cc. of Tincture, and mix thoroughly.

"Preserve in tightly-stoppered bottles, using only glass or rubber stoppers. Alcohol content, by volume, 82 to 84 per cent." *U. S.*

The British Pharmacopœia 1914 recognizes two tinctures of iodine; a strong, containing 10 per cent. of free iodine, and a weak representing 2.5 per cent. of iodine. The formulas for these are as follows:

Tinctura Iodi Mitis (*Weak Tincture of Iodine*).

"Iodine, 25 *grammes;* Potassium Iodide, 25 *grammes;* Distilled Water, 25 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Potassium Iodide and Iodine in the Distilled Water; add sufficient of the Alcohol to produce the required volume." *Br.*

"10 millilitres of the Tincture, diluted with 20 millilitres of *water,* require for decolorisation not less than 19.2 or more than 19.8 millilitres of *N/10 solution of sodium thiosulphate.* This Weak Tincture contains 0.025 gramme of Iodine in each millilitre; 1 minim contains about $^{1}/_{44}$ grain. It is not of the same strength as the Tinctura Iodi of the International Agreement. It contains the same proportion of Iodine as the Tinctura Iodi of the British Pharmacopœia, 1898." *Br.*

Tinctura Iodi Fortis (*Strong Tincture of Iodine*).

"Iodine, 100 *grammes;* Potassium Iodide, 60 *grammes;* Distilled Water, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Potassium Iodide and the Iodine in the Distilled Water; add sufficient of the Alcohol to produce the required volume." *Br.*

"Five millilitres of the Tincture, diluted with 20 millilitres of *water,* require for decolorisation not less than 38.4 or more than 39.6 millilitres of *N/10 solution of sodium thiosulphate.* This Strong Tincture contains 0.1 gramme of Iodine in each millilitre; 1 minim contains about $^{1}/_{11}$ grain. It is of approximately the same strength as the Tinctura Iodi of the International Agreement. It contains approximately the same proportion of Iodine as the Liquor Iodi Fortis of the British Pharmacopœia, 1898." *Br.*

The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stoppered bottles, in order to prevent the evaporation of the alcohol. It should never be dispensed in cork-stoppered vials, because of the destructive action of the iodine on the cork; rubber or glass stoppers should be used.

Assay for Potassium Iodide.—"Measure exactly 5 cc. of Tincture of Iodine, evaporate in a tared dish or watch glass on a water bath, and then add several small successive portions of water, drop by drop, until all of the iodine has volatilized and a white residue remains. The residue should weigh not less than 0.225 Gm. and not more than 0.275 Gm. and should respond to the tests for identity found under *Potassii Iodidum.*

"**Assay for Iodine.**—Measure exactly 5 cc. of the Tincture, dilute with 25 cc. of distilled water, and titrate the solution with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01269 Gm. of I." *U. S.*

L. F. Kebler (*J. Ind. & E. C.*, 1913, p. 484) reports the results of analyses of a number of samples collected in pharmacies in the District of Columbia in which the iodine content ranged from 1.97 Gm. to 9.26 Gm. in 100 cc. and the potassium iodide content from 0.0 to 6.82 Gm. in 100 cc. Such variations of course are due to carelessness, or dishonesty, in making it and not to changes or deterioration taking place in the properly made article which has been found by numerous investigators to be a very stable preparation.

J. W. Mardin (*J. A. P. A.*, 1913, p. 1464) gives a method of determining the alcohol in this preparation by a series of factors based upon the alterations in sp. gr. produced respectively by potassium iodide and iodine and gives tables which may be consulted for the determination by this method.

Tincture of iodine when made with plain alcohol and no potassium iodide, as is done in numerous foreign Pharmacopœias, and was formerly the practice in the U. S. P., is a very unstable preparation. The alcohol reacts with the iodine to form ethyl iodide. This has the effect of making the tincture more readily miscible with water, but the per cent. of free iodine drops to one-half of its original amount in a very short time. It was discovered that the use of a certain proportion of potassium iodide stabilized the preparation very satisfactorily. The potassium iodide in this preparation, therefore, is not used for its solvent effect but as a preservative ingredient.

If the tincture is exposed to the air, as in an imperfectly stoppered bottle, it will gain appreciably in strength as the alcohol volatilizes much more rapidly than does the iodine. Such a preparation should not be applied to the skin for fear of producing blisters or burns.

Uses.—Tincture of iodine is now employed almost exclusively for its local effects. It is a powerful local irritant acting somewhat slowly but with great persistence. If applied too freely it will produce an acute dermatitis with desquamation of the cuticle. It is a favorite remedy as a counter-irritant in inflammations of the joint, especially when of a more or less chronic type, thus it is widely employed in *sprains* after the stage of acute inflammation has subsided, in *chronic rheumatism, arthritis deformans, gout, chilblains, myalgias,* and the like. In *scrofulous glands* and chronic rheumatic conditions it is often applied with the idea of obtaining the constitutional action of the iodine from absorption through the skin as well as the local counter-irritant effect. While it is true that if evaporation is guarded against perceptible amounts of iodine may be absorbed, after the application of the tincture to the skin, as ordinarily employed, the quantity taken up by the system is insignificant. The irritant action of tincture of iodine is also made use of for the obliteration of serous cavities, as in the radical cure of *hydrocele* or *ovarian dropsies.*

As pointed out elsewhere, iodine is a powerful germicide and within the last few years the tincture of iodine has become a valuable addition to the surgeon's armamentarium against infections. It is very widely used for the purpose of sterilizing the skin, before operation or for hypodermic injections. For disinfecting *wounds* the U. S. tincture should be diluted with equal parts of water; the weaker tincture of the Br. is a satisfactory strength for this purpose. It is also employed as a local remedy in the treatment of *erysipelas,* but its application requires some caution and it is better to surround the inflamed surface with a border of the tincture, embracing a portion of both the sound and diseased skin with the idea of preventing the progress of the inflammation, than to attempt a complete cure by covering the whole surface affected.

Luc has found the inhalation of the fumes from slightly warmed tinctures very useful in *coryza.*

Under the erroneous title of *colorless tincture of iodine* various combinations manufactured from tincture of iodine have been prepared. These preparations are calculated to mislead practitioners, for they contain no free iodine and therefore have not the therapeutic virtues of the official tincture, but are variable mixtures consisting principally of ammonium iodide and various other compounds of iodine. (See *Tinctura Iodi Decolorata,* N. F., Part III.)

Lugol's solution (*Liquor Iodi Compositus*) is a much preferable preparation for the internal administration of iodine.

Dose, one to five minims (0.06–0.3 cc.).

TINCTURA JALAPÆ. Br.

TINCTURE OF JALAP

Teinture (alcoolé) de Jalap, *Fr. Cod.;* Jalapentinktur, *G.*

"Jalap, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with one hundred millilitres of the Alcohol; pack in a percolator; gradually add more of the Alcohol until six hundred millilitres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter. Determine the amount of Jalap Resin present in ten millilitres of the strong tincture so prepared by the process described under 'Jalapæ Resina,' and dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a Tincture of Jalap containing 1.5 grammes of the Resin in 100 millilitres. When 10 millilitres of the Tincture, concentrated by evaporation, are mixed with eight times their volume of *water,* the resin thus separated, washed with *water* and dried at a gentle heat, weighs not less than 0.145 or more than 0.155 gramme." *Br.*

This tincture is no longer official in the U. S. Pharmacopœia, but is in the N. F. (see Part III).

This tincture is now prepared on the basis of proportion of resin, not of crude drug, as formerly. It possesses the medicinal virtues of jalap, and is sometimes added to cathartic mixtures.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA JALAPÆ COMPOSITA. Br.

COMPOUND TINCTURE OF JALAP

Aqua Vitæ Germanica; Tintura Alcoholica de Jalapa Composita, *Sp.*

"Jalap, in No. 40 powder, 80 *grammes;* Scammony Resin, in powder, 15 *grammes;* Turpeth, in No. 40 powder, 10 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the mixed powders with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is also official in the N. F. IV (see Part III). It is a harsh but active purgative, capable of producing serious effects if given in over-dose.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA KALADANÆ. Br.

TINCTURE OF KALADANA

"Kaladana, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the alcohol, and complete the *percolation process.*" *Br.*

This is a new tincture of the British Pharmacopœia 1914. It is used as a cathartic in doses of one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA KINO. U. S., Br.

TINCTURE OF KINO Tr. Kino

Teinture (alcoolé) de Kino, *Fr. Cod.;* Kinotinktur, *G.*

"Kino, 100 Gm.; to make 1000 cc. Place the kino in a capacious flask, and pour on it 500 cc. of boiling water. Agitate the mixture thoroughly, and heat it for one hour on a water bath containing boiling water, shaking it frequently. Allow the liquid to cool, add enough recently boiled water to make the product measure 500 cc., and add 500 cc. of alcohol. Stopper the flask, set it aside in a cool place for twenty-four hours, and then decant the mixture through cheese cloth.

"Preserve in a cool, dark place, in small bottles, tightly stoppered. Alcohol content, by volume, 45 to 47 per cent." *U. S.*

"Kino, in powder, 100 *grammes;* Glycerin, 150 *millilitres;* Distilled Water, 250 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Mix the Glycerin and the Distilled Water; rub the Kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder of the mixture; transfer to a closed vessel; add five hundred millilitres of the Alcohol; set aside for twelve hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

An important operation in the process of the U. S. Pharmacopœia is the employment of heat. This is due to the researches of Edmund White (*P. J.*, 1903, May, 644, and Nov., 702), who with David Hooper showed that the gelatinization of tincture of kino is due to an enzyme or oxydase present in the kino; the activity of this is destroyed by heat. This very simple procedure makes it unnecessary to comment upon the numerous formulas which filled the pharmaceutical literature of bygone years, in which all sorts of expedients were resorted to, in order to prevent the gelatinization of this preparation, which almost invariably occurred and which was a constant source of loss to the pharmacist. Tincture of kino is one of the most frequently prescribed astringents, especially in the treatment of *diarrhea.*

Dose, one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Tinctura Kino et Opii Composita, *N. F.*

TINCTURA KRAMERIÆ. U. S., Br.

TINCTURE OF KRAMERIA

Tincture of Rhatany; Teinture Ratanhia, *Fr. Cod.;* Tinctura Ratanhiæ, *P. G.;* Ratanhiatinktur, *G.*

"Krameria, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using diluted alcohol as the menstruum.

"Alcohol content, by volume, 40 to 45 per cent." *U. S.*

"Krameria Root, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

It is stated that the tincture made from Pará rhatany furnishes a clear solution on the addition of water, while that from Peruvian root yields a turbid mixture.

The same precaution should be observed in keeping this tincture as is recommended for tincture of kino. It is a good preparation in cases which admit of the use of small quantities of alcohol.

Dose, one or two fluidrachms (3.75 or 7.5 cc.).

TINCTURA LAVANDULÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF LAVENDER Tr. Lavand. Co. [Compound Spirit of Lavender]

Spiritus Lavandulæ Compositus, *U. S.* 1870; Lavender Drops; Teinture de Lavande composée, *Fr.;* Zusammengesetzte Lavendeltinktur, *G.*

"Oil of Lavender, 8 cc.; Oil of Rosemary, 2 cc.; Cinnamon, in moderately coarse powder, 20 Gm.; Clove, in moderately coarse powder, 5 Gm.; Myristica, in moderately coarse powder, 10 Gm.; Red Saunders, in moderately coarse powder, 10 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, macerating the mixed drugs in a mixture of 750 cc. of alcohol, in which the oils have been dissolved, and 250 cc. of water. Complete the preparation with a menstruum of 3 volumes of alcohol and 1 volume of water.

"Alcohol content, by volume, 67 to 72 per cent." *U. S.*

"Oil of Lavender, 5.0 *millilitres;* Oil of Rosemary, 0.5 *millilitre;* Cinnamon Bark, bruised, 10.0 *grammes;* Nutmeg, bruised, 10.0 *grammes;* Red Saunders Wood, rasped, 20.0 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000.0 *millilitres.* Macerate the solid ingredients and the Oils with nine hundred millilitres of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The compound tincture of lavender of the U. S. Pharmacopœia is nearly twice the strength of the British preparation, although it is made with a menstruum weaker in alcohol. When properly prepared it is an excellent preparation to be used for *gastric uneasiness, nausea,* and *flatulence.*

Dose, from thirty minims to a fluidrachm (1.8–3.75 cc.).

TINCTURA LIMONIS. U. S., Br.

TINCTURE OF LEMON Tr. Limon. [Tincture Limonis Corticis U. S. P. IX]

Alcoolature de Citron, *Fr. Cod.;* Teinture de Zeste de Citron, *Fr.;* Citronenschalentinktur, *G.;* Alcohol de Corteza de Cidra, *Sp.*

"Lemon Peel (the outer yellow rind, grated from the fresh fruit), 500 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, macerating the drug in 1000 cc. of alcohol, and complete the preparation with alcohol. Use purified cotton as the filtering medium.

"Alcohol content, by volume, 70 to 75 per cent." *U. S.*

"Lemon Peel, cut small, 250 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture was doubled in strength at the 1898 revision of the Br. Pharm., but is still only about one-half the strength of the U. S. tincture. It is made with strong alcohol instead of proof spirit formerly used. It forms a grateful aromatic addition to tonic infusions, etc.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Syrupus Acidi Citrici, *U. S.*

TINCTURA LOBELIÆ. U. S.

TINCTURE OF LOBELIA Tr. Lobel. [Lobeliæ tinctura P. I.]

Teinture de Lobélie, *Fr. Cod.;* Tinctura Lobeliae, *P. G.;* Lobelientinktur, *G.;* Tintura di lobelia, *It.;* Tintura alcoholica de lobelia, *Sp.*

"Lobelia, in moderately coarse powder, 100 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using diluted alcohol as the menstruum.

"Alcohol content, by volume, 44 to 47 per cent." *U. S.*

For method of assay, see *C. D.,* 1893, 454; also *P. J.,* 1895, 141.

It possesses the emetic and narcotic properties of lobelia, and is much used in *asthma.* A saturated tincture is strongly recommended by A. Livezey as a local application in *erysipelas,* and in the *eczematous eruption* of *Rhus poisoning.* (*B. M. S. J.,* lv, 262.)

Dose, as an expectorant, fifteen to thirty minims (0.9–1.8 cc.).

TINCTURA LOBELIÆ ÆTHEREA. Br.

ETHEREAL TINCTURE OF LOBELIA

Teinture ethérée de Lobélie enflée, *Fr.;* Ætherische Lobelientinktur, *G.*

"Lobelia, in No. 40 powder, 200 *grammes;* Spirit of Ether, sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred *millilitres* of the Spirit of Ether, and complete the *percolation process.*" *Br.*

It should be noted that this tincture is twice the strength of the U. S. tincture and the International Protocol.

Dose, from five to fifteen minims (0.3–0.9 cc.).

TINCTURA MYRRHÆ. U. S., Br.

TINCTURE OF MYRRH Tr. Myrrh.

Teinture (alcoolé) de Myrrhe, *Fr. Cod.;* Tinctura Myrrhae, *P. G.;* Myrrhentinktur, *G.;* Tintura di mirra, *It.;* Tintura alcoholica de mirra, *Sp.*

"Myrrh, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using alcohol as the solvent.

"Alcohol content, by volume, 83 to 88 per cent." *U. S.*

"Myrrh, in coarse powder, 200 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Macerate the Myrrh with eight hundred millilitres of the Alcohol in a closed vessel for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The strength of this tincture was increased 60 per cent. at the revision of the British Pharmacopœia (1898) and is now equivalent to the U. S. preparation.

Official alcohol is preferable to diluted alcohol as a solvent of myrrh, because it forms a perfectly clear tincture, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. According to E. B. Shuttleworth (*A. J. P.,* xliii, 369), the gum which is left behind in making the tincture may be utilized for making mucilage. The tincture of myrrh is used solely as a local application to stimulate *indolent and foul ulcers, spongy gums, aphthous sore mouth,* and *ulcerations of the throat.*

Dose, from fifteen to thirty minims (0.9–1.8 cc.).

TINCTURA NUCIS VOMICÆ. U. S., Br.

TINCTURE OF NUX VOMICA Tr. Nuc. Vom. [Strychni tinctura P. I.]

"Tincture of Nux Vomica yields, from each 100 cc., not less than 0.237 Gm. and not more than 0.263 Gm. of the alkaloids of nux vomica." *U. S.* "Tincture of Nux Vomica contains in 100 millilitres 0.125 gramme of strychnine." *Br.*

Teinture (alcoolé) de Noix vomique, *Fr. Cod.;* Tinctura Strychni, *P. G.;* Brechnusstinktur, Krähenaugentinktur, *G.;* Tintura di noce vomica, *It.;* Tintura alcoholica de nuez vomica, *Sp.*

"Nux Vomica, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using a mixture of 10 cc. of acetic acid, 750 cc. of alcohol, and 240 cc. of water as the first menstruum, and completing the percolation with a mixture of 3 volumes of alcohol and 1 volume of water. Adjust the volume of the finished tincture by the addition of sufficient of the second menstruum to make each 100 cc. contain 0.25 Gm. of the alkaloids of nux vomica. Cool the Tincture in a proper container by exposure to a temperature of 5° C., and filter.

"Alcohol content, by volume, 67 to 72 per cent." *U. S.*

"Liquid Extract of Nux Vomica, 50 *milli-*

litres; Distilled Water, 150 *millilitres;* Alcohol (90 per cent.), sufficient to produce 600 *millilitres.* Mix; filter if necessary. Examined by the process described under 'Extractum Nucis Vomicæ Liquidum,' Tincture of Nux Vomica is found to contain in 100 millilitres 0.125 gramme of strychnine. *Limit of error* 0.005 gramme in excess or defect. This Tincture contains in each millilitre 1.25 milligrams of strychnine; each fluidrachm contains about $^1/_{16}$ grain. It contains approximately the same proportion of strychnine as the Tinctura Nucis Vomica of the International Agreement, and one-half of that contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay.—"Proceed by Type Process D, taking 50 cc. of Tincture of Nux Vomica, use chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.0364 Gm. of the alkaloids of nux vomica (Proximate Assays)." *U. S.*

Great variations in procedure have marked the course of this tincture in the former editions of the U. S. P. As made from a standardized extract or a fluidextract the strength was usually satisfactory but the color of the preparation was too variable. The present U. S. P. method affords a product which is uniform both in appearance and alkaloidal content.

The British Pharmacopœia standardizes the liquid extract, and makes its tincture from it of such strength that 100 cc. shall contain 0.125 Gm. of strychnine.

The amount of strychnine in this tincture is so small that it is not to be recommended for producing the systemic effects of that alkaloid. Its most important use is as a bitter tonic in *gastric atony.*

Dose, of the tincture, ten to thirty minims (0.6–1.8 cc.), to be increased if necessary.

Off. Prep.—Elixir Phosphori et Nucis Vomicæ, *N. F.*

TINCTURA OLIVERI CORTICIS. Br.

TINCTURE OF OLIVER'S BARK

"Oliver's Bark, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has been used in Australia for a number of years and is now official in the Br. Pharm. 1914. It possesses the properties of an aromatic like cinnamon.

The *dose* is from one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA OPII. U. S., Br.

TINCTURE OF OPIUM Tr. Opii [Tinctura Opii Deodorati U. S. P. IX, Laudanum, Tincture of Deodorized Opium, Opii tinctura P. I.]

"Tincture of Opium yields, from each 100 cc., not less than 0.95 Gm. and not more than 1.05 Gm. of anhydrous morphine." *U. S.*

"Opium contains in 100 millilitres 1 gramme of morphine, calculated as anhydrous." *Br.*

Tinctura Thebaica, Tinctura Meconii, Tinctura Extracti Opii; Teinture d'Extrait d'Opium, *Fr. Cod.;* Teinture (alcoolé) d'Opium, Teinture thébaïque, *Fr.;* Tinctura Opii Simplex, *P. G.;* Einfache Opiumtinktur, *G.;* Tintura di oppio, *It.;* Tintura alcoholica de opio, *Sp.*

There has been a marked change in the formula for this tincture in the U. S.; the preparation at present official under the name of Tincture of Opium is practically the same as that which was recognized previously as Tincture of Deodorized Opium and the plain Tincture of Opium, corresponding to the Br. preparation, has been entirely omitted.

"Granulated Opium, 100 Gm.; Paraffin, 50 Gm.; Alcohol, 200 cc.; Water, a sufficient quantity to make about 1000 cc. Heat 500 cc. of water to boiling, pour it on the granulated opium contained in a suitable vessel, and stir the mixture frequently during twenty-four hours. Transfer the mixture to a percolator, and, when the original menstruum has ceased to drop, continue the percolation slowly, gradually adding water until the opium is exhausted. Concentrate the percolate by evaporation on a water bath until it measures 150 cc., add the paraffin, and continue the heating until this is entirely melted. Beat the mixture thoroughly and set it aside to cool. When cool, pierce a hole through the top layer of paraffin and drain off the liquid, add to this 600 cc. of water, and filter, add the alcohol to the filtered liquid, and wash the residual paraffin and the filter with small portions of water until the combined liquids measure 950 cc. Assay a portion of this liquid as directed below, and, from the morphine content thus determined, ascertain by calculation the amount of anhydrous morphine in the remainder of the liquid, and adjust the volume of the finished Tincture by the addition of a mixture of 1 volume of alcohol and 4 volumes of water, to make each 100 cc. contain 1 Gm. of anhydrous morphine.

"Alcohol content, by volume, 17 to 19 per cent." *U. S.*

"Opium, 200 *grammes;* Alcohol (90 per cent.), Distilled Water, of each, *a sufficient quantity.* Rub the Opium to a paste with five hundred *millilitres* of Distilled Water, previously heated to at least 90° C.; set aside for six hours; add five hundred *millilitres* of the Alcohol; mix thoroughly; set aside in a covered vessel for twenty-four hours; strain, and then press; mix the two liquids thus obtained; set aside for twenty-four hours; filter. Determine the proportion of morphine, calculated as anhydrous, in the strong tincture so prepared by the following process:" *Br.*

Assay.—"Evaporate 80 cc. of Tincture of Opium on a water bath until the alcohol is removed. Then proceed as directed in the assay under *Opium,* beginning with the word 'transfer.' The result of the assay indicates the amount of morphine obtained from 40 cc. of the Tincture of Opium." *U. S.*

"Pour 40 millilitres of the liquid into a porcelain dish; evaporate on a water bath until the volume is reduced to about 10 millilitres; mix the residual liquid in a mortar with 1 gramme of freshly slaked *lime;* dilute the mixture with water to 41 *millilitres;* set aside for half an hour, stirring from time to time. Filter off 25 millilitres of the liquid (representing 25 millilitres of the strong tincture) through a plaited filter, having a diameter of about one decimetre, into a convenient vessel; add 2.5 millilitres of *alcohol* (90 per cent.) and 15 millilitres of *ether;* shake the mixture; add 1 gramme of *ammonium chloride;* shake well and frequently during half an hour; set aside for twelve hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the vessel as completely as possible by means of a small pipette, and transfer it to the filter; rinse the vessel with 8 millilitres of *ether,* again transferring the ethereal layer, by means of the pipette, to the filter; wash the filter with a total amount of 5 millilitres of *ether* added slowly, and in portions; let the filter dry in the air; pour upon it the liquid in the bottle, in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the vessel with *morphinated water.* Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain and dry it first at 60° C., and finally at 115° C. for two hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0.2 gramme of the crystals, and titrate, with *N/10 solution of sulphuric acid,* as directed under 'Opium.' Add to the weight of anhydrous morphine obtained, as indicated by the titration, 0.025 gramme, a portion representing the average loss of morphine during the process. Having thus ascertained the proportion of morphine calculated as anhydrous, present in 25 millilitres of the strong tincture, dilute the remainder of the latter with sufficient of a mixture of Alcohol (90 per cent.) and Distilled Water, in equal volumes, to produce Tincture of Opium containing 1 gramme of morphine, calculated as anhydrous, in 100 millilitres. Examined by the foregoing process, Tincture of Opium is found to contain in 100 millilitres 1 gramme of morphine, calculated as anhydrous. *Limit of error* 0.05 gramme in excess or defect. This Tincture contains in 100 millilitres 1 gramme of morphine, calculated as anhydrous; 110 minims contain 1 grain of the same. It is of approximately the same strength as the Tinctura Opii of the International Agreement, and is about one-third stronger than the corresponding preparation of the British Pharmacopœia, 1898. Tincture of Opium may be prepared with any variety of opium containing a known percentage of morphine, calculated as anhydrous, provided that the percentage is not less than seven and a half, and provided that the resulting Tincture of Opium responds to the foregoing test." *Br.*

There were formerly a number of official liquid preparations of opium of the same drug strength, *i.e.,* the *vinegar,* the *wine,* the *tincture* and the *deodorized tincture.* The vinegar and wine have been long since dismissed from the official list.

The deodorized tincture had its origin in *Battleys sedative-drops,* a proprietary preparation of a century ago.

The advantages of a preliminary treatment of the opium or its extract with a solvent capable of removing waxy, fatty and caoutchouc-like constituents of the drug, without diminishing the content of narcotic alkaloids was soon appreciated. Methyl acetate, ether, paraffin and benzin have all been suggested and used. The latter, however, has the advantage of cheapness and yields a very satisfactory product. The large increase in the use of the deodorized tincture has led to the replacement by it, as an official article, of the plain tincture previously known and used.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter, but containing traces of morphine. According to the requirements of the Pharmacopœia, 10 minims of this tincture will contain about one-tenth of a grain of morphine. Because of the other narcotic principles of opium, however, the clinical effects are somewhat stronger; the narcotic action of ten minims of the tincture of opium (0.6 cc.) is nearly equivalent to one-sixth of a grain (0.01 Gm.) of morphine. Its action differs slightly from that of pure morphine, it being more constipating and more nauseating. As pointed out under opium the other alkaloids present seem to lessen the depressant effect of morphine upon the respiratory center so that the crude drug is a somewhat safer form of narcotic than pure opium.

The tincture of opium is probably the best of the official preparations where the effects of the whole drug are desired. It should be recollected that a fluidrachm of laudanum will yield on an average about one-hundred and twenty drops. When long kept with occasional exposure to the air, it becomes thick from the evaporation of a portion of the alcohol and the deposition of solid matter. If given in this state, it often acts with unexpected energy, and death has resulted in infants from doses which would have been entirely safe if the tincture had not been concentrated in this way.

Dose, five to ten minims (0.3–0.6 cc.).

Off. Prep.—Linimentum Opii, *Br.;* Tinctura Camphoræ Composita, *Br.;* Tinctura Opii Ammoniata, *Br.;* Linimentum Opii Compositum, *N.*

F.; Lotio Plumbi et Opii, *N. F.;* Mistura Carminativa, *N. F.;* Mistura Copaibæ et Opii, *N. F.;* Mistura Magnesiæ, Asafœtidæ et Opii, *N. F.;* Mistura Opii et Chloroformi Composita, *N. F.;* Mistura Opii et Rhei Composita, *N. F.;* Tinctura Opii et Gambir Composita, *N. F.*

TINCTURA OPII AMMONIATA. Br.

AMMONIATED TINCTURE OF OPIUM

Scotch Paregoric; Teinture d'Opium ammoniacale, *Fr.;* Ammoniakalische Opiumtinktur, *G.*

"Tincture of Opium, 100 *millilitres;* Benzoic Acid, 20 *grammes;* Oil of Anise, 5 *millilitres;* Solution of Ammonia, 200 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Oil of Anise and the Benzoic Acid in six hundred millilitres of the Alcohol; add the Tincture of Opium and the Solution of Ammonia; mix; filter; add sufficient of the Alcohol to produce the required volume. This Tincture contains in 100 millilitres 0.1 gramme of morphine, calculated as anhydrous; 110 minims contain about 1/10 grain of the same. It contains approximately one-tenth less morphine than that contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is an old preparation of the Edinburgh Pharmacopœia, formerly used in Scotland under the name of *Paregoric Elixir.* It differs, however, both in composition and in strength, from the very popular preparation known as Paregoric in the United States.

Dose, from thirty minims to a fluidrachm (1.8–3.75 cc.).

TINCTURA OPII CAMPHORATA. U. S. (Br.)

CAMPHORATED TINCTURE OF OPIUM Tr. Opii Camph. [Paregoric, Opii tinctura benzoici P. I.]

Tinctura Camphoræ Composita, *Br.;* Compound Tincture of Camphor; Paregoric Elixir; Tinctura Thebaica Benzoica; Elixir Parégorique, Teinture d'Opium Camphrée, *Fr.;* Tinctura Extracti Opii Camphorata, Elixir Paregoricum, Tinctura Opii benzoïca, *P. G.;* Benzoësaurehaltige Opiumtinktur, *G.*

"Powdered Opium, 4 Gm.; Benzoic Acid, 4 Gm.; Camphor, 4 Gm.; Oil of Anise, 4 cc.; to make 1000 cc. Prepare a Tincture by Type Process M, macerating the ingredients in a mixture of 40 cc. of glycerin and 950 cc. of diluted alcohol, completing the preparation with diluted alcohol.

"Alcohol content, by volume, 43 to 46 per cent." *U. S.*

"Tincture of Opium, 50 *millilitres;* Benzoic Acid, 5 *grammes;* Camphor, 3 *grammes;* Oil of Anise, 3 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Benzoic Acid, Camphor, and Oil of Anise in nine hundred *millilitres* of the Alcohol; add the Tincture of Opium and sufficient of the Alcohol to produce the required volume; filter if necessary. This Compound Tincture contains in 10 millilitres 5 milligrammes (0.005 gramme) of morphine, calculated as anhydrous; and in each fluid drachm about one thirty-seventh of a grain of the same. It contains approximately one-tenth more morphine than the Tinctura Opii Benzoica of the International Agreement, and one-tenth more than was contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is widely employed with the idea that it is a mild anodyne for the relief of *cough, nausea,* and abdominal *pains.* As its narcotic effects depend, however, entirely upon the opium which it contains its mildness is due solely to the fact that it is usually given in relatively small doses. In *diarrheas* the effect of the opium is somewhat enhanced by the camphor. The superstition that it is especially suited for children is senseless; if morphine be indicated for infants the alkaloid itself is just as useful if given in equivalent dose. One-half a fluidounce of either the United States or British tincture contains about nine-tenths of a grain of powdered opium.

Although this preparation is exempted from the provisions of the Harrison Anti-Narcotic Act, it has been frequently used by opium habitues when other forms of the narcotic are unobtainable and few pharmacists will sell more than one ounce to a customer.

Dose, for an infant, from five to twenty minims (0.3–1.3 cc.); for an adult, from one to four fluidrachms (3.75–15.0 cc.).

Off. Prep.—Mistura Glycyrrhizæ Composita, *U. S.;* Mistura Pectoralis, Stokes, *N. F.*

TINCTURA PICRORHIZÆ. Br.

TINCTURE OF PICRORHIZA

"Picrorhiza, cut small and bruised, 250 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

Although "this Tincture is of twice the strength of the corresponding preparation of the Indian and Colonial Addendum, 1900," *Br.,* the proportion of alcohol in this tincture is too large for it to be available as an antiperiodic; it is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA PODOPHYLLI. Br.

TINCTURE OF PODOPHYLLUM

Teinture de Résine de Podophyllum, *Fr.;* Podophyllintinktur, *G.*

"Podophyllum Resin, 36.5 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Add the Podophyllum Resin to nine hundred *millilitres* of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The introduction of this tincture is of doubtful utility.

Dose, five to fifteen minims (0.3–0.9 cc.).

TINCTURA PODOPHYLLI INDICI. Br.

TINCTURE OF INDIAN PODOPHYLLUM

"Indian Podophyllum Resin, 36.5 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Add the Indian Podophyllum Resin to nine hundred millilitres of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

This has been introduced to afford a substitute in the Asiatic provinces for the tincture of podophyllum.

Dose, five to fifteen minims (0.3–0.9 cc.).

TINCTURA PRUNI VIRGINIANÆ. Br.

TINCTURE OF WILD CHERRY

Tincture of Virginian Prune; Teinture d'Ecorce de Cerisier, *Fr.;* Wildkirschenrindentinktur, *G.*

"Wild Cherry Bark, in No. 20 powder, 200 *grammes;* Alcohol (90 per cent.), 565 *millilitres;* Distilled Water, 365 *millilitres;* Glycerin, 100 *millilitres.* Mix the powder with the Distilled Water; set aside in a closed vessel for twenty-four hours; add the Alcohol, and complete the *maceration process;* add the Glycerin to the product." *Br.*

This was a new official tincture of the Br. Pharm., 1898; its utility is doubtful. The English name has been changed from Virginian Prune to Wild Cherry in the Br. Pharm., 1914. The use of the glycerin serves to retard precipitation.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA PYRETHRI. Br.

TINCTURE OF PYRETHRUM Tr. Pyreth.
[Tincture of Pellitory]

Teinture de Pyrèthre, *Fr. Cod.;* Bertramwurzeltinktur, *G.*

"Pyrethrum Root, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred and fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is a powerful local irritant, and is an ingredient in several mouth and tooth washes. For its uses, which are purely external, see *Pyrethrum.*

TINCTURA QUASSIÆ. Br.

TINCTURE OF QUASSIA

Teinture de Quassia, *Fr.;* Quassiatinktur, *G.*

"Quassia Wood, rasped, 100 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture is no longer recognized by the U. S. That formerly official was twice as strong as the Br. It was prepared as follows: "Quassia, in No. 50 powder, *two hundred grammes,* to make *one thousand mils.* Prepare a Tincture by Type Process P, using a mixture of *one volume* of alcohol and *two volumes* of water as the menstruum." *U. S. IX.*

It may be employed as an addition to tonic infusions or mixtures. It has the advantage of being free from tannin, and may be given in conjunction with salts of iron.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA QUILLAIÆ. Br.

TINCTURE OF QUILLAIA

Teinture de Quillaya, Teinture d'Ecorce de Panama, *Fr.;* Seifenrindentinktur, *G.*

Tincture of quillaja has been deleted from the U. S., but is official in the N. F. (see Part III).

"Quillaia Bark, in No. 20 powder, 50 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with twenty-five millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is almost exclusively used as an emulsifying agent. Its medicinal activity, however, limits its use. (See *Quillaja.*)

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

TINCTURA QUININÆ. Br.

TINCTURE OF QUININE

Teinture de Quinine, *Fr.;* Chinintinktur, *G.*

"Quinine Hydrochloride, 20 *grammes;* Tincture of Orange, 1000 *millilitres.* Dissolve." *Br.*

Quinine sulphate was replaced in this preparation by the hydrochloride in the 1885 Br. Pharmacopœia, because, as pointed out by Wright (*Y. B. P.,* 1884, 537), the sulphate was not always soluble in the proportion of tincture of orange peel ordered.

Dose, a fluidrachm (3.75 cc.) (about equal to one and two-tenths grains of quinine hydrochloride).

TINCTURA QUININÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF QUININE

Teinture Ammoniacale de Quinine, *Fr.;* Ammoniakhaltige Chinintinktur, *G.*

"Quinine Sulphate, 20 *grammes;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the Solution of Ammonia with the Alcohol; add the Quinine Sulphate; shake until a clear solution is produced; set aside for three days; filter." *Br.*

Dose, one fluidrachm (3.75 cc.), representing about one and two-tenths grains of quinine sulphate.

TINCTURA RHEI. U. S. (Br.)

TINCTURE OF RHUBARB Tr. Rhei

Tinctura Rhei Composita, *Br.;* Compound Tincture of Rhubarb; Teinture de Rhubarbe, *Fr. Cod.;* Rhabarbertinktur, *G.;* Tintura di rabarbaro, *It.*

"Rhubarb, in moderately coarse powder, 200 Gm.; Cardamom Seed, in moderately coarse powder, 30 Gm.; to make 1000 cc. Prepare a

Tincture by Type Process P, using a mixture of 100 cc. of glycerin, 500 cc. of alcohol, and 400 cc. of water as the first menstruum, completing the percolation with diluted alcohol.

"Alcohol content, by volume, 43 to 46 per cent." *U. S.*

"Rhubarb, in No. 20 powder, 100.0 *grammes;* Cardamom Seeds, in No. 20 powder, 12.5 *grammes;* Coriander Fruit, in No. 20 powder, 12.5 *grammes;* Glycerin, 100.0 *millilitres;* Alcohol (45 per cent.), sufficient to produce 1000.0 *millilitres.* Moisten the solid ingredients with one hundred millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty millilitres of tincture. Add the Glycerin, and sufficient of the Alcohol to produce the required volume." *Br.*

Like several other tinctures, this is one which has been found difficult to stabilize. Glycerin minimizes the tendency to precipitate. The precipitate is in part chrysophanic acid which is one of the less valuable medicinal constituents of the drug, so a small amount of precipitation in this preparation may be disregarded.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Mistura Opii et Rhei Composita, *N. F.*

TINCTURA RHEI AROMATICA. U. S.

AROMATIC TINCTURE OF RHUBARB
Tr. Rhei Arom.

Teinture (alcoolé) de Rhubarbe aromatique, *Fr.;* Aromatische Rhabarbertinktur, *G.*

"Rhubarb, in moderately coarse powder, 200 Gm.; Cinnamon, in moderately coarse powder, 40 Gm.; Clove, in moderately coarse powder, 40 Gm.; Myristica, in moderately coarse powder, 20 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using a mixture of 100 cc. of glycerin, 500 cc. of alcohol, and 400 cc. of water as the first menstruum, completing the percolation with diluted alcohol.

"Alcohol content, by volume, 43 to 46 per cent." *U. S.*

This is the tincture which is used in making the aromatic syrup of rhubarb. It is preferable to separate the preparations, as it is occasionally desirable to prescribe the tincture without the admixture with syrup, while the pharmacist will always prefer to make the tincture in quantity and keep it on hand, since it is permanent, and add to it syrup to make the aromatic syrup when needed.

Dose, for an adult, from one-half to one fluidrachm (1.8–3.75 cc.).

Off. Prep.—Syrupus Rhei Aromaticus, *U. S.*

TINCTURA SCILLÆ. U. S., Br.

TINCTURE OF SQUILL Tr. Scill.

"Tincture of Squill, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.0055 cc., and not more than 0.0065 cc., equivalent to not less than 0.000,000,46 Gm. and not more than 0.000,000,54 Gm. of ouabain, for each Gm. of body weight of frog." *U. S.*

Teinture de Scille, *Fr. Cod.;* Meerzwiebeltinktur, *G.;* Tintura alcoholica de escila, *Sp.*

"Squill, in coarse powder, 100 Gm.; Alcohol, Water, each, a sufficient quantity to make about 1000 cc. Moisten the drug with sufficient menstruum, prepared by mixing 3 volumes of alcohol and 1 volume of water, and macerate in a closed vessel in a moderately warm place for twenty-four hours, stirring occasionally. Then transfer it to a percolator, shake it down evenly without packing, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the same menstruum until the percolate measures 950 cc. Assay a portion of this percolate as directed below, and, from the result thus obtained, adjust the volume of the finished Tincture by the addition of menstruum to conform to the above biological standard.

"Alcohol content, by volume, 64 to 67 per cent.

"**Assay.**—Proceed as directed under *Tinctura Digitalis.*" *U. S.*

"Squill, bruised, 200 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The tincture represents the virtues of squill probably better than any other official preparation.

Dose, from ten to twenty minims (0.6–1.3 cc.).

TINCTURA SENEGÆ. Br.

TINCTURE OF SENEGA

Teinture de Polygala de Virginie, *Fr.;* Senegatinktur, *G.*

"Senega Root, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent. The tincture is efficient, but it is hardly needed while recourse can be had to the fluidextract or the syrup.

Dose, from thirty minims to two fluidrachms (1.8–7.5 cc.).

TINCTURA SENNÆ COMPOSITA. Br.

COMPOUND TINCTURE OF SENNA

Elixir Salutis; Teinture de Séné composée, Teinture de Séné aromatique, Elixir de Salut, *Fr.;* Zusammengesetzte Sennatinktur, *G.*

"Senna Leaves, in No. 20 powder, 200 *grammes;* Caraway Fruit, in No. 20 powder, 25 *grammes;* Coriander Fruit, in No. 20 powder, 25 *grammes;* Glycerin, 100 *millilitres;* Alcohol (45 per cent.), sufficient to produce

1000 *millilitres.* Moisten the solid ingredients with two hundred and fifty millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty millilitres of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." *Br.*

The Br. Pharm. 1898 increased the proportion of senna in this preparation 60 per cent.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in *costiveness* attended with flatulence, and in *atonic gout,* especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. Tincture of senna yields a yellow scaly deposit, containing white crystals of calcareous salts. (Ménière.)

Dose, from two to four fluidrachms (7.5–15 cc.).

TINCTURA SERPENTARIÆ. Br.

TINCTURE OF SERPENTARY

Teinture de Serpentaire de Virginie, *Fr.;* Schlangenwurzeltinktur, *G.*

" Serpentary Rhizome, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is little other than a feebly aromatic, alcoholic stimulant. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent.

Dose, thirty minims to two fluidrachms (1.8–7.5 cc.).

TINCTURA STRAMONII. U. S., Br.

TINCTURE OF STRAMONIUM Tr. Stramon.

" Tincture of Stramonium yields, from each 100 cc., not less than 0.0225 Gm. and not more than 0.0275 Gm. of the alkaloids of stramonium." *U. S.*

Tincture of Stramonium Leaves; Teinture de Stramoine (feuille), *Fr.;* Stechapfelblättertinktur, *G.*

" Stramonium, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Prepare a Tincture by Type Process P as modified for assayed tinctures, using diluted alcohol as the menstruum, and adjust the volume of the finished Tincture by the addition of diluted alcohol to make each 100 cc. contain 0.025 Gm. of the alkaloids of stramonium.

" Alcohol content, by volume, 44 to 47 per cent.

" **Assay.**—Proceed by Type Process D, taking 100 cc. of Tincture of Stramonium, use chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of stramonium (Proximate Assays)." *U. S.*

" Stramonium Leaves, in No. 20 powder, 200 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The British tincture is now double the strength of the U. S. P. tincture.

Dose, from ten to twenty minims (0.6–1.3 cc.); of the British tincture, five to ten minims (0.3–0.6 cc.).

TINCTURA STROPHANTHI. U. S., Br.

TINCTURE OF STROPHANTHUS Tr. Strophanth. [Strophanthi tinctura P. I.]

" Tincture of Strophanthus, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.00,005,5 cc. and not more than 0.00,006,5 cc., equivalent to not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each Gm. of body weight of frog." *U. S.*

Teinture de Strophantus, *Fr. Cod.;* Tinctura Strophanthi, *P. G.;* Strophanthustinktur, *G.;* Strophanthussamentinktur, *G.;* Tinctura di strofanto, *It.;* Tintura alcoholica de estrofanto, *Sp.*

" Strophanthus, in moderately coarse powder, 100 Gm.; to make about 1000 cc. Pack the Strophanthus in a cylindrical glass percolator, provided with a stop-cock and arranged with a cover and a receptacle suitable for volatile liquids, and percolate it slowly with purified petroleum benzin until a few drops of the percolate, evaporated from filter paper, leave no greasy stain. Reject the benzin percolate. Remove the powdered drug from the percolator, and expose it to the air until the odor of benzin is no longer noticeable. Prepare from this a tincture by Type Process P as modified for assayed tinctures, using alcohol as the menstruum, and allowing the moistened drug to macerate for forty-eight hours before starting the percolation, instead of twenty-four hours as directed in Type Process P. Adjust the volume of the finished Tincture to conform to the above biological standard. Alcohol content, by volume, 88 to 92 per cent.

" **Assay.**—Proceed as directed under *Tinctura Digitalis.*" *U. S.*

" Strophanthus Seeds, in No. 30 powder, dried at 45° C., 100 *grammes;* Ether, *a sufficient quantity;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Pack the powder in a percolator; moisten with the Ether, and macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 50° C. Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until five hundred millilitres of percolate are obtained; add sufficient of the Alcohol to produce the required volume. This Tincture is made with four times the proportion of Strophanthus Seeds ordered for the corresponding preparation of the British Pharmacopœia, 1898. It is of approximately the same strength as the Tinctura Strophanthi of the International Agreement, but in the case of the latter Tincture, the seeds are not treated with ether for the removal of fat and resins." *Br.*

H. Helch found diluted alcohol yielded the best tincture, the one with highest strophanthin content; that extraction with strong alcohol apparently tended to decompose strophanthin into strophanthidin; that tinctures made from seed defatted with petroleum ether had no higher strophanthin content than tinctures made from natural seed. (*Chem. Abs.*, 1919, xiii, 496.) Karam Samaan (*C. D.*, 1919, xci, 802) has also come to the like conclusion that strong alcohol can not extract the activity of strophanthus and recommends the use of 65 per cent. alcohol. The use of petroleum benzin in the U. S. P. IX and ether in the Br. P. for the preliminary exhaustion of the drug is to effect the removal of the fixed oil which interferes with the stability of the preparation unless previously removed. By these expedients a preparation which was formerly very unsatisfactory, on account of its turbid and unsightly condition, has been very much improved.

In spite of the researches which are quoted above the official menstruum for the U. S. P. X tincture of strophanthus is strong alcohol.

It is stated that when tincture of strophanthus is mixed with water and allowed to stand, the active principles undergo hydrolysis with the formation of a toxic substance, the identity of which has not yet been established. (*Schweiz. Apoth. Zeit.* through *Pract. Drug.*, 1916, p. 39.)

The question of deterioration of the tincture of strophanthus has been the subject of some difference of opinion. In the experiments of Pomeroy and Heyl (*A. J. P.*, 1922, xciv, p. 479) there was no appreciable deterioration when properly stored even after a period of five years, and according to Hatcher and Baily (*J. A. M. A.*, 1909, lii, p. 5), it is much more uniform in strength than tincture of digitalis.

Uses.—The tincture of strophanthus fully represents the crude drug and may be used for all the purposes for which strophanthus is serviceable.

Dose, three to eight minims (0.2–0.5 cc.).

TINCTURA TOLU. U. S. (Br.)

TINCTURE OF TOLU Tr. Tolu. [Tinctura Tolutana U. S. IX, Tolu Tincture]

Tinctura Tolutana, *Br.;* Tinctura Balsami Tolutani; Tincture of Balsam of Tolu; Teinture de Baume de Tolu, *Fr. Cod.;* Tolubalsamtinktur, *G.*

"Tolu, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process M, using alcohol as the solvent.

"Alcohol content, by volume, 80 to 85 per cent." *U. S.*

"Balsam of Tolu, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Balsam of Tolu in eight hundred *millilitres* of the Alcohol; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The British tincture (1914) is half the strength of the U. S. P. tincture.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in *chronic bronchitis,* but the proportion of alcohol is too large to allow of its advantageous use in some cases. It is used in preparing the syrup of tolu. In smaller quantities it is often employed to flavor cough mixtures. It is precipitated by aqueous liquids.

Dose, one-half to two fluidrachms (1.8–7.5 cc.).

Off. Prep.—Syrupus Tolu, *U. S.*

TINCTURA URGINEÆ. Br.

TINCTURE OF URGINEA

"Urginea, bruised, 200 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture was introduced into India and is intended to be used in place of squill.

The *dose* is five to fifteen minims (0.3–0.9 cc.).

TINCTURA VALERIANÆ. U. S.

TINCTURE OF VALERIAN Tr. Valer

Teinture de Valériane, *Fr. Cod.;* Tinctura Valerianæ, *P. G.;* Baldriantinktur, *G.;* Tinturo di valeriana, *It.*

"Valerian, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using a mixture of 3 volumes of alcohol and 1 volume of water as the menstruum.

"Alcohol content, by volume, 66 to 70 per cent." *U. S.*

The tincture possesses the properties of valerian, but cannot be given in some cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit.

Dose, one to four fluidrachms (3.75–15.0 cc.).

TINCTURA VALERIANÆ AMMONIATA. U. S., Br.

AMMONIATED TINCTURE OF VALERIAN Tr. Valer. Ammon.

Tinctura Valerianæ Composita; Teinture de Valériane ammoniacale, *Fr.;* Ammoniakalische Baldriantinktur, *G.*

"Valerian, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using aromatic spirit of ammonia as the menstruum.

"Alcohol content, by volume, 62 to 65 per cent." *U. S.*

"Valerian Rhizome, in No. 40 powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the liquid ingredients, and, using the mixture as a menstruum, prepare by the *maceration process.*" *Br.*

The proportion of valerian was increased 60 per cent. in the Br. Pharm. 1898, and the aromatic spirit of ammonia replaced by alcohol, solution of ammonia, and volatile oils.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medicinal action. The quantity of valerian was very judiciously increased one-third in the U. S. revision of 1880. The tincture is employed as an antispasmodic in *hysteria* and other *nervous diseases.*

Dose, from thirty minims to a fluidrachm (1.8–3.75 cc.).

TINCTURA VALERIANÆ INDICÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF INDIAN VALERIAN

"Indian Valerian Rhizome, in No. 40 powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the liquid ingredients, and, using the mixture as a menstruum, prepare by the *maceration process.*" *Br.*

This tincture was introduced into the Br. Pharm. 1914 to be used in India and elsewhere in place of ammoniated tincture of valerian.

Dose, thirty minims to one fluidrachm (1.8–3.75 cc.).

TINCTURA VERATRI VIRIDIS. U. S.

TINCTURE OF VERATRUM VIRIDE Tr. Verat. Vir.

Tinctura Veratri; Tincture of Green Hellebore; Tincture of American Hellebore; Teinture (alcoolé) de Vératre, *Fr.;* Tinctura Veratri, *P. G.;* Nieswurzeltinktur, *G.*

"Veratrum Viride, in moderately coarse powder, 100 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using alcohol as the menstruum.

"Alcohol content, by volume, 88 to 92 per cent." *U. S.*

The U. S. tincture of American hellebore of 1890 was of the same strength as *Norwood's tincture,* which was prepared by its author from fresh drug (240 grains for each fluidounce of alcohol), and was supposed to be saturated. The present tincture represents 10 per cent. of the drug, in conformance with the recommendations of the Brussels Congress concerning potent tinctures (see *Tincturæ*).

For uses see *Veratrum Viride.*

Dose, ten to thirty minims (0.6–1.8 cc.).

TINCTURA ZINGIBERIS. U. S., Br.

TINCTURE OF GINGER Tr. Zingib. [Tincture of Jamaica Ginger]

Teinture de Gingembre, *Fr.;* Tinctura Zingiberis, *P. G.;* Ingwertinktur, *G.*

"Ginger, in moderately coarse powder, 200 Gm.; to make 1000 cc. Prepare a Tincture by Type Process P, using a mixture of 850 cc. of alcohol and 150 cc. of water as the menstruum.

"Alcohol content, by volume, 74 to 78 per cent." *U. S.*

"Ginger, in No. 40 powder, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The strength of this tincture was reduced at the 1880 revision one-third, to bring it into the 20 per cent. class; this is not a disadvantage, however, in view of the introduction of the fluidextract, and the dose is not now inconveniently large.

The tincture of the British Pharmacopœia is still too weak in the proportion of ginger, being only half the strength of the U. S. tincture. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid, and the drug is incompletely exhausted of its resinous and oily constituents. Official Jamaica ginger only should be used; for, while a darker-colored preparation is made when the inferior varieties are substituted, the apparent increase in strength is due to coloring matter, and not to the presence of a larger amount of volatile oil or resin. It has been shown by carefully conducted experiments that the addition of a small proportion of water to the alcoholic menstruum may be made without injury to the strength of the preparation in terms of resinous matter and flavor.

Tests for Purity.—The U. S. gives the following organoleptic test: "Evaporate 10 cc. of Tincture of Ginger to dryness in a small flask. Add 5 cc. of half-normal alcoholic potassium hydroxide, and boil the mixture gently for thirty minutes under a reflux condenser. Remove the condenser, and evaporate the alcohol on a water bath. Then add 50 cc. of distilled water to the residue, agitate the mixture, filter, transfer the aqueous filtrate to a separatory funnel, and shake it out with 25 cc. of ether. Evaporate the separated ether solution spontaneously by adding it, a few drops at a time, to the center of a watch glass, and cautiously apply the tip of the tongue to the dry residue. The taste should be slightly camphoraceous but not sharp or bitingly pungent (*capsicum or similar pungent substitute*)." *U. S.*

This is another of the numerous alcoholic preparations of the U. S. P. that have been placed on the interdicted list by the Prohibition authorities.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures in debilitated states of the alimentary canal. It is in this country largely used for the preparation of a syrup of ginger, for which purpose, however, the fluidextract is official, and is better even than the strong tincture of the Br. Pharmacopœia 1885, which was dropped at the 1898 revision.

Dose, eight to forty minims (0.5–2.5 cc.).

Off. Prep.—Acidum Sulphuricum Aromaticum, *U. S., Br.*

TOLU. U. S. (Br.)

TOLU [Balsamum Tolutanum U. S. P. IX, Balsam of Tolu]

"Tolu is a balsam obtained from *Toluifera Balsamum* Linné (Fam. *Leguminosæ*)." *U. S.* "Balsam of Tolu is a solid balsam obtained from incisions made in the trunk of Myroxylon toluiferum, *H. B. and K.*" *Br.*

Balsamum Tolutanum, *Br.;* Balsamum Americanum; Resina Tolutana; Baume de Tolu, Baume de Carthagène, *Fr.;* Tolubalsam, *G.;* Balsamo Tolutano, Balsamo del Tolu, *It.;* Bálsamo de Tolu, *Sp.*

This balsam, like balsam of Peru, has been the subject of much controversy. This is not only seen in the distinct sources above given by the U. S. and British Pharmacopœias, but is rendered more confusing by the fact that the German Pharmacopœia prescribes "the air hardened balsam of *Myroxylon balsamum* (L.) Harms var. *genuinum* Baillon." In addition to this Tschirch regards the tree yielding balsam of Tolu like that of the tree yielding balsam of Peru, merely physiological varieties of *Toluifera Balsamum* L.

Toluifera Balsamum L. (*Myroxylon toluiferum* H. B. and K.) is a tree with spreading crown, somewhat like *Toluifera Pereiræ,* differing from it mainly by its habit of branching about 14–16 m. above ground, in having leaves with fewer leaflets and in bearing dense racemes of flowers each with a tubulary calyx. Most of the balsam is obtained in the province of Tolu along the Magdalena River in Colombia.

The balsam is said to be produced normally in the tree only in young growing tissues such as the young twigs and leaves, and to be formed in the older tissues only as the result of injuries received. It is procured by making V-shaped incisions in the trunk quite through the bark. The juice is received in small calabash cups, which are inserted in slight excavations beneath the point of the two vertical incisions meeting at the lower end; and Weir has seen as many as twenty cups at a time on one tree. The collectors go from tree to tree, emptying the cups into flasks of raw-hide. In these skin vessels the balsam is shipped to Cartagena and Savanilla where it is transferred to cylindrical tin cans, containing 10 to 25 pounds and exported.

Schaer has reported on *Myrocarpus Balsam* (*Cabureiba Balsam,* of Piso; *Baume du Perou en coques,* of Guibourt), and concludes that it has intermediate properties between balsam of Tolu and balsam of Peru. It did not contain cinnamic acid and the benzoic acid which he obtained had a melting point from 3° to 4° higher than normal benzoic acid. (*A. Pharm.,* 1909, p. 176.)

Description and Physical Properties.—As first imported, balsam of Tolu has a soft tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like rosin. It is shining, translucent, of a reddish or yellowish-brown color, a highly fragrant odor, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odor while burning. It is entirely soluble in volatile oils.

"A brown or yellowish-brown, plastic solid, transparent in thin layers and brittle when old, dried, or exposed to cold. It has a pleasant, aromatic odor resembling that of vanilla, and a mild aromatic taste. Tolu is nearly insoluble in water and in petroleum benzin. It is soluble in alcohol, chloroform, and ether. It dissolves in solutions of the fixed alkalies, usually leaving an insoluble residue.

"An alcoholic solution of Tolu (1 in 20) is acid to litmus paper. Shake about 1 Gm. of Tolu with 25 cc. of carbon disulphide, allow it to stand for thirty minutes, filter the liquid, and evaporate 15 cc. of the filtrate to dryness. The residue thus obtained, when dissolved in glacial acetic acid, does not show a green color on the addition of a few drops of sulphuric acid (*rosin*). The remaining portion of the filtrate, when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000), does not acquire a green color (*rosin or copaiba*). Dissolve about 1 Gm. of Tolu, accurately weighed, in 50 cc. of neutral alcohol, add 1 cc. of phenolphthalein T.S., and titrate the solution with half-normal alcoholic potassium hydroxide. The acid number thus obtained is not less than 112 and not more than 168. Add sufficient half-normal alcoholic potassium hydroxide to the neutralized liquid obtained in the preceding test to make the total volume of the volumetric alkali solution exactly 20 cc., heat the liquid on a water bath for half an hour under a reflux condenser, and cool. Mix this liquid with 200 cc. of distilled water, or more if necessary, and titrate the excess of potassium hydroxide with half-normal sulphuric acid. The total volume of half-normal potassium hydroxide corresponds to a saponification value of not less than 154 and not more than 220." *U. S.*

"A soft, tenacious solid when first imported, becoming harder and finally brittle. Transparent and yellowish-brown in thin films. Pressed between pieces of glass with the aid of heat, and examined with a lens, it exhibits crystals of cinnamic acid. Odor fragrant, especially when warmed; taste aromatic and slightly acid. Soluble in *alcohol* 90 per cent.), the solution being acid to *litmus. Acid value* 107.4 to 147.2; *saponification value* 170 to 202. If 5 grammes are gently warmed with three successive portions of 25, 15, and 10 millilitres of *carbon disulphide,* the solution yields, when evaporated to dryness, a distinctly crystalline residue, which, when tested as described under 'Styrax Præparatus' yields not less than 1.25 grammes of balsamic acids." *Br.*

The carbon disulphide test is based upon Braithwaite's researches upon spurious balsams of Tolu. (See *P. J.,* 1895, 145; also 1897, 307.)

Hatchett states that when dissolved in the smallest quantity of solution of potassium hydroxide it loses its own characteristic odor and acquires that of the clove pink. G. L. Ulex gives as a test of the purity of the balsam, that if heated in sulphuric acid it dissolves without disengagement of sulphurous acid, and yields a cherry-red liquid. A modification of this test is that of R. A. Cripps (*P. J.*, xix, 1888), who states that by a comparative test of the suspected balsam with a pure specimen 1 per cent. of storax or other resinous adulterant can be detected. Thirty grammes of the sample are digested in carbon disulphide for fifteen minutes with gentle warmth, the clear liquid decanted, evaporated to dryness, and dissolved in sulphuric acid. A bright red rose color is produced, remaining rose for a length of time if the balsam be pure, rapidly becoming brown if the balsam has been adulterated.

Constituents.—Tolu balsam like that of Peru is a mixture of resinous matter with cinnamic and benzoic acids and esters of these acids. The proportion of resinous matter is larger than in Peru balsam, amounting to 75 or 80 per cent. It consists, according to Tschirch and Oberlander (*A. Pharm.*, 1894, 599), largely of the esters of an alcohol, *toluresinotannol.* The total aromatic acids, according to Cocking and Kettel (*P. J.*, 1918), amount to about 36 per cent., of which some 12 per cent. is free cinnamic acid and 8 per cent. free benzoic. When distilled with water it yields a small quantity, 1.5 to 3 per cent., of a highly aromatic volatile oil. Deville in 1841 found this oil to consist largely of a liquid principle to which he gave the name of *tolene* but which is probably identical with phellandrene ($C_{10}H_{16}$). This volatile oil, according to Parry (*Chemistry of Essential Oils*, etc., 1919), has the following characteristics: Sp. gr., 0.949 to 1.080; optical rotation, -2 to $+1$; refractive index, 1.5440 to 1.5600; acid number, 5 to 20; ester number, 175 to 210. The oil contains benzyl bonzoate, benzyl cinnamate, phellandrene, and farnesol. A factitious balsam described by R. V. Mattison (*A. J. P.*, 1876, 51) contained 63 per cent. of storax.

Tolu balsam is sometimes adulterated with rosin and pine resins, both of which are readily detected, as they are soluble in carbon disulphide and benzol. The Balsam of Tolu of commerce is sometimes deficient in alcohol-soluble contents. Occasionally, the cans of shipment of tolu contain large pieces of red brick with enough melted balsam poured in to completely cover the bricks and fill the cans.

Uses.—Balsam of Tolu is a feeble stimulant expectorant; the syrup of Tolu is much used, on account of its agreeable flavor, as the basis of cough mixtures. Old and obstinate *catarrhs* are said to be sometimes greatly relieved by the inhalation of the vapor proceeding from an ethereal solution of this balsam. The best form of administration is that of emulsion, made by triturating the balsam with mucilage and loaf sugar, and afterwards with water.

Dose, ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Syrupus Tolu, *U. S.* (from the tincture), *Br.;* Tinctura Benzoini Composita, *U. S., Br.;* Tinctura Tolu, *U. S., Br.*

TONGA. N. F.

TONGA

"Tonga is a mixture of equal parts of the bark of *Premna arborea* (Forster filius) Farwell (Fam. *Verbenaceæ*) and of the root of *Epipremnum pinnatum* (Linné) Engler (Fam. *Araceæ*). Tonga contains not more than 5 per cent. of foreign organic matter." *N. F.*

The natives of the Fiji Islands have long employed a mixture of two barks as a medicine.

Epipremnum pinnatum (L.) Engler (*Rhaphidophora Vitiensis* Schott.) (Fam. *Araceæ*) is a climbing shrub which grows in various islands of the Malaysian region.

Premna Taitensis Schauer (*Scrophulariodes arborea* Forst. f., *P. arborea* (Forst. f.) Farwell, n. comb.), is a verbenaceous tree with opposite leaves, cymose flowers and drupaceous fruits, indigenous to the Fiji, Tonga and other islands of the Pacific. The natives of these islands call it "*Yoro*" and "*Awalho.*"

Description and Physical Properties.—"*Unground Tonga.*—In small chips or quills up to about 11 cm. in length, 2 cm. in width and 3 mm. in thickness, outer surface of chips brownish with numerous prominent, irregular longitudinal ridges some of which are of a pale yellow color giving the surface a striated appearance; fracture hard and short. Root: in cylindrical pieces up to about 6 cm. in length and about 3 cm. in diameter; outer surface light yellowish brown to dark brown with the light yellowish cork partially exfoliated; numerous root-scars or root remains along one surface; internally very fibrous and tough. Taste slight; odor slight.

"*Powdered Tonga.*—Dark brown; spiral or scalariform tracheæ with lignified walls, the spiral tracheæ from 0.020 to 0.080 mm. in diameter, the scalariform tracheæ from 0.150 to 0.250 mm. in diameter; numerous simple to many-compound starch grains, the simple grains spheroidal or ellipsoidal up to about 0.020 mm. in diameter; numerous fragments composed of long lignified fibers with thick porous walls associated with rectangular medullary ray cells with lignified walls and large simple pores; fragments composed of starch bearing parenchyma associated with thick-walled stone-cells with simple or branching pores or non-lignified fibers the latter frequently branched and resembling two parallel fibers, one longer than the other, united near the middle by a short connecting portion, the whole structure with a continuous lumen; numerous fragments of cork tissue some of which are composed of cells with lignified walls; calcium oxalate in crystal fibers or in rosettes, the latter up to 0.095 mm. in diameter." *N. F.*

The presence of a liquid alkaloid, tongine, has been reported but there is no definite information concerning it.

Uses.—This drug was introduced to the medical profession by Ringer and Murrell (*L. L.*, 1880, ii) as a remedy for *neuralgia.* A few authors reported favorably on its effect but it has not achieved the confidence of the medical profession. A proprietary preparation asserted to contain tonga has been used for rheumatism. What claim the drug has to official recognition is a mystery.

Dose, given by the N. F., thirty grains (2 Gm.).

Off. Prep.—Fluidextractum Tongæ, *N. F.;* Elixir Tongæ et Salicylatum, *N. F.*

TOXITABELLÆ HYDRARGYRI CHLORIDI CORROSIVI. U. S.

POISON TABLETS OF CORROSIVE MERCURIC CHLORIDE Toxitabel. Hydrarg. Chlor. Corr. [Corrosive Sublimate Tablets, Bichloride Tablets]

"Tablets of an angular shape, not discoid, each having the word *'Poison'* and the skull and cross bones design distinctly stamped upon it. Each tablet weighs about 1 Gm. and contains not less than 0.45 Gm. and not more than 0.55 Gm. of corrosive mercuric chloride ($HgCl_2$), the remainder consisting chiefly of either sodium chloride [NaCl] or ammonium chloride [NH_4Cl]. The tablets are to be colored blue, preferably with sodium indigotindisulphonate. Poison Tablets of Corrosive Mercuric Chloride are to be dispensed in securely stoppered glass containers on the exterior of which is placed a red label bearing the word *'Poison'* and a statement indicating that the Tablets contain the required amount of corrosive mercuric chloride." *U. S.*

Hydrargyrum Bichloratum Compressum; Pastilli Sublimati.

Assay.—"Proceed as directed under *Hydrargyri Chloridum Corrosivum,* using one tablet and washing the sulphide with distilled water until the filtrate is colorless and until a 5 cc. portion of the washings, acidulated with nitric acid, yields no turbidity on the addition of a few drops of silver nitrate T.S. The weight of the mercuric sulphide obtained, multiplied by 1.167, indicates its equivalent in corrosive mercuric chloride. Tablets of Corrosive Mercuric Chloride may also be assayed as directed under the electrolytic method." *U. S.*

Uses.—The convenience of tablets of corrosive sublimate for the preparation of antiseptic solutions, and their wide use, has led to the introduction of such a tablet into the Pharmacopœia. Because of the large number of cases of poisoning through the inadvertent swallowing of these tablets, in the place of compressed tablets of certain drugs which may have a somewhat similar appearance, it has become highly desirable that these tablets be made in such a form as to render such a mistake less liable. A variety of suggestions for this purpose have been made; among the most popular shapes are the oblong or coffin-shaped, and the triangular tablets. As the solution formed by these tablets is colorless, in order that the solution shall not be confounded with harmless drugs, the tablets are directed to be colored blue by the addition of sodium indigotindisulphonate, or other dye.

A bluish color is greatly preferable to a pink dye, which is sometimes used, not only because it is less liable to be confused with reddish colored drugs but because various confections are often colored red. Despite these precautions, however, it is probable that cases of poisoning by mercuric chloride, either accidental or intentional, will continue to occur from time to time. The physician, therefore, should exercise the greatest reserve in allowing tablets of corrosive sublimate to get into the hands of his patients and the pharmacist should be exceedingly careful in selling and dispensing them. The official tablet contains 0.5 Gm. (8.0 grains) of corrosive sublimate; one of them dissolved in one pint of water (500 cc.) makes a solution of 1 to 1000. The addition of sodium chloride in these tablets aids in the solution of the mercuric chloride.

TRAGACANTHA. U. S., Br.

TRAGACANTH Trag. [Gum Tragacanth]

"Tragacanth is the dried gummy exudation from *Astragalus gummifer* Labillardière, or other Asiatic species of *Astragalus* (Fam. *Leguminosæ*)." *U. S.* "Tragacanth is a gummy exudation obtained by incision from Astragalus gummifer, *Labill.*, and some other species of Astragalus. Known in commerce as Syrian tragacanth." *Br.*

Gummi Tragacanthæ vel Astragalorum; Gomme Adragante, *Fr. Cod.;* Tragacantha, *P. G.;* Tragant, Traganth, *G.;* Gomma adragante, Dragante, *It.;* Gomo tragacanto, *Sp.*

Tragacanth is one of the oldest drugs in the Materia Medica. It was known in the days of Theophrastus, who described it three centuries before the Christian Era. It has been official in every edition of the U. S. P. since 1820.

The Astragalus plants are herbs or low shrubs with odd-pinnate, rarely simple leaves, white, yellow or purple flowers, arranged in racemes or spikes and membranous, or fleshy fruits.

Numerous species belonging to the genus *Astragalus* yield a gummy matter having the properties of *tragacanth.* The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. Tragacantha* L. (*A. massiliensis* Lam.), which grows in southern Europe and northern Africa and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. creticus* Lam.) which grows in Crete and Ionia, and on that of Olivier, to *A. verus,* which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer* which he found growing on Mount Libanus in Syria, and from which tragacanth exudes. Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkestan, one of which proved to be *A. gummifer* of Labillardière which was said to yield a white variety, and the other a new species, which he called *A. strobiliferus,* and which was said to yield a red and inferior product. The fact seems to be that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble one another that botanists have found some difficulty in distinguishing them. They are very abundant on the mountains of Asia Minor, and, according to information received by M. J. Léon Soubeiran from Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the *A. creticus* of Lamarck. It is in the Anti-Taurus range that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary tissues, which alone yield the gum. This exudes very slowly, flowing at night, and ceasing during the day; two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion.

According to a recent report from the Revenue Commissioner of Mesopotamia, Tragacanth is collected by tapping the small Astragalus shrubs which grow in the mountainous regions of southern Persia and from thence through the entire mountainous region which runs northwest along the frontiers of Mesopotamia, including northern Arabistan, the Luristan–Pust-i-Kut country and Kurdistan. In collecting the gum, the Kurds are said to first burn all the leaves off the shrubs, then expose the roots, cut incisions in the roots and leave for a week or more; they then return and collect the gum which exudes from the roots, the gum obtained from the first tapping is of superior quality, that from subsequent tappings being inferior and of yellow colors. The Kurds bring the gum to Suleimanaya, an important collecting center in Kurdistan. Here it is bought by local merchants who export it to Bagdad, from whence it is exported to Europe and America. (*A. J. P.,* 1920, 38.) The section *Tragacantha* of the genus *Astragalus* includes the principal species which yield gum tragacanth.

According to Haussknecht, tragacanth is yielded by the following species of Astragalus: *A. adscendens* Boiss. et Hausskn. (southern Persia); *A. leioclados* Boiss. (in middle and western Persia, by Ispahan and Hamadan); *A. brachycalyx* Fisch. (Kurdistan and Luristan); *A. gummifer* Labill. (widely distributed from Lebanon to Armenia and in the northern regions of the Euphrates and Tigris); *A. microcephalus* Willd. (the same as *A. gummifer* Labill., and also in Asia Minor); *A. pycnocladus* Boiss. et Hausskn. (particularly in western Persia); *A. stromatodes* Bge. (in Achyr Dagh, in Northern Syria); *A. kurdicus* Boiss. (Aintab). Other species that yield a tragacanth gum are *A. heratensis* Bge., of the Khorasan Mountains, which yields a gum known as "kutira," and *A. parnassi* Boiss. var. *cyllenea,* found on the mountains of Peloponnesus.

Harris states that the best Smyrna tragacanth is produced in Asia Minor. It is not, however, collected in the immediate vicinity of Smyrna, but comes from Karahissar, Jalowadsch, and even farther in the interior, where the plant grows wild. This kind of gum consists of white, yellow, and red, hardened pieces, which have become congealed after oozing out of the bush or tree in the hot sun of a Levantine summer. The gum is secured in a similar manner as opium by an incision in the branch. This is done in the spring and summer of each year, and the gum is usually scraped in September, when the first rains begin to fall.

The nature of the incision influences the shape of the pieces of tragacanth. The color is influenced both by the length of time consumed in drying on the bark and by the sequence of the tapping. The first tapped gum is always lighter than that of subsequent tappings. The commercial supplies of tragacanth used in this country are imported chiefly from London. Small quantities come direct from Shiraz, Persia and Bombay, India. During the last twenty years the gum tragacanth trade of Smyrna has decreased.

Tragacanth occurs either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended. In commerce certain varieties of tragacanth are recognized and usually known by the name of the locality from which they have been produced or through which they have entered commerce. The ordinary tragacanth, tragacanth in sorts, sometimes known as *traganton* or *common tragacanth,* occurs in irregular pieces; Smyrna tragacanth appears usually in broad, thick flakes, yellowish or brownish; Syrian tragacanth, also called Leaf Gum, in thin, ribbon-like, white flakes, is obtained in Kurdistan and Persia. This is the best grade on the market.

Vermiform tragacanth occurs in thin, narrow, vermiform bands which are usually twisted or coiled. It is obtained largely in north Morea from *Astragalus cylleneus* Boiss. et Heldr. From the researches of Hugo von Mohl, which have been confirmed by Wigand (*A. J. P.,* xxxi, 243) it would seem that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith and those of the medullary rays which traverse the ligneous part of the stem and older branches. (*A. J. P.,* xxxi, 243.)

Description and Physical Properties.—"*Unground Tragacanth*—In flattened, lamellated, frequently curved fragments or in straight or spirally twisted linear pieces from 0.5 to 2.5 mm. in thickness; whitish to light brown, translucent and horny; fracture short; rendered more easily pulverizable by heating to 50° C.; inodorous; taste insipid, mucilaginous.

"*Structure*—A mass showing the distorted and swollen lamellæ of mucilaginous walls and a few starch grains.

"*Powdered Tragacanth*—White; angular fragments of mucilage with circular or irregular lamellæ; starch grains from 0.003 to 0.025 mm. in diameter, spherical to elliptical, with occasional 2- to 4-compound grains, many of the grains being swollen and more or less altered. The powder shows few or no fragments of lignified vegetable tissue (*Indian gum*).

"Add 1 Gm. of Tragacanth to 50 cc. of distilled water: it swells and forms a smooth, nearly uniform, stiff, opalescent mucilage free from cellular fragments. Shake 2 Gm. of Tragacanth with 100 cc. of water until fully swollen and free from lumps, then add 2 Gm. of powdered sodium borate, and shake the mixture thoroughly until the salt is dissolved: the mucilage does not lose its transparency, nor exhibit any change in consistence, and on pouring is not slimy or stringy even after standing twenty-four hours (*foreign gums*). Boil 1 Gm. of Tragacanth with 20 cc. of water until a mucilage is formed, then add 5 cc. of hydrochloric acid, and again boil the mixture for five minutes: it develops no pink or red color (*Indian gum*)." *U. S.*

"Thin flattened flakes, irregularly oblong, or more or less curved, marked on the surface by concentric ridges. Frequently two and a half centimetres long, and twelve millimetres wide. White or pale yellowish-white, somewhat translucent. Horny, fracture short. Inodorous; almost tasteless. Sparingly soluble in *water,* but swelling into a gelatinous mass, which may be tinged violet or blue by *N/10 solution of iodine.* Ash not more than 4 per cent." *Br.*

It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar at the temperature of 50° C. Its sp. gr. is 1.384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arabic, the other swelling in water, but not dissolving. To separate the soluble from the insoluble part requires agitation with separate portions of water; the solutions are to be decanted and filtered, and the process is to be continued until water ceases to dissolve anything.

Constituents.—The chemistry of tragacanth needs further study. According to O'Sullivan (*Proc. Chem. Soc.,* 1901) the soluble part—which is the greater portion—is made up chiefly of polyarabinan-trigalactan-geddic acid; this yields on hydrolysis, arabinose, galactose and *geddic acid.* The insoluble part is mostly *bassorin,* $(C_{11}H_{20}O_{10})_n$; bassorin acted on by baryta water forms two isomers, alpha- and beta-tragacanthan-xylan-bassoric acid which on hydrolysis yield *tragacanthose,* xylose and *bassoric acid.*

There is present also small amounts of cellulose, starch and protein substances.

It is stated by S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania, which, as they are originally of a dark color and destitute of the flaky form of the genuine gum, are broken into small fragments and whitened by means of lead carbonate before being mixed with the tragacanth. Hanbury states, in confirmation of this, that he has detected lead in the *small tragacanth* imported into London. (*P. J.,* xv, 20.) Gum tragacanth has been recently admixed with and substituted by inferior gums from India and Persia, obtained from *Cochlospermum* and *Sterculia* species which have been imported under the names of Indian-, Karaya-, Kuteera-, Kadaya-, and Maura gum. Among these have been the gums of *Cochlospermum gossypium* DC. (Fam. *Bixaceæ*) and *Sterculia urens* (Fam. *Sterculiaceæ*). These occur in irregular vermiform or rounded tears having a dull, rough surface and pale brownish or pinkish-brown pieces, some of which have adherent bark. C. O. Ewing in *J. A. Ph. A.,* 1918, 789 states that karaya gum absorbs large quantities of water, swelling considerably and forming a tasteless, nearly colorless mucilage. A 1 per cent. mucilage of karaya had a viscosity about like a 3/4 per cent. mucilage of tragacanth. The adhesiveness of a 1 per cent. tragacanth mucilage is superior to that of a 1 per cent. karaya mucilage. As an emulsifying agent, karaya appears good though from one-third to one-half more should be used and it may be objectionable sometimes because of its acidity. It is detected by the official tests. The powdered drug is not only adulterated with the Indian gum, but with powdered acacia, dextrin, wheat and corn-starch. Payet gives a test for the detection of acacia in powdered tragacanth which depends on the brown color produced by the oxidase of the former when brought in contact with an aqueous solution of guaiacol in the presence of hydrogen dioxide. (*Ann. de Chim. Analyt.,* x, p. 63.)

Uses.—Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water renders it useful for the suspension of heavy insoluble powders, and it is also employed in pharmacy to impart consistence to troches, for which it answers better than does gum arabic, and in making emulsions, although for these purposes it is inferior to acacia. It is also used for its demulcent action in *pharyngitis* by allowing a piece of the gum to dissolve slowly in the mouth. It is officially employed as the basis of many of the troches.

Off. Prep.—Glycerinum Tragacanthæ, *Br.;* Mucilago Tragacanthæ, *U. S., Br.;* Pulvis Tragacanthæ Compositus, *Br.;* Glyceritum Tragacanthæ, *N. F.*

TRIFOLIUM. N. F.

TRIFOLIUM Trifol. [Red Clover Blossoms]

"Trifolium is the dried inflorescence of *Trifolium pratense* Linné (Fam. *Leguminosæ*). Trifolium contains not more than 2 per cent. of foreign organic matter." *N. F.*

Red Clover, Clover, Trefoil; Trèfle Rouge, *Fr.;* Klee, Rothklee, *G.;* Trifoglio, *It.*

The clovers are so well known as not to require any extended description. The official species, which is a native of Europe but widely cultivated in the U. S., is characterized by its sessile papilionaceous flowers in dense heads, sweet-scented, and with a purplish corolla which withers after flowering; the stems are ascending and somewhat hairy. The three ovate leaflets are notched at the end and marked on the upper side with a pale spot.

The drug comes chiefly from the southern Appalachian district and from Germany.

Description and Physical Properties.—"*Unground Trifolium.*—Heads ovoid with rounded summit, mostly from 12 to 25 mm. in length and width, shriveled, purplish and more or less brown from drying, consisting of many small papilionaceous flowers, crowded together and clothed at the base with broad, pointed ciliate stipules of a pale green color with darker veins, and which may or may not be accompanied by diminutive trifoliate leaves. Flowers from 12 to 15 mm. in length, longer than the four, nearly equal calyx teeth and shorter than the narrower fifth calyx tooth; calyx-teeth subulate, tapering; petals united into a tube below, the standard longer than the wings but when recurved appearing shorter; stamens diadelphous (nine and one); style slender. Odor faintly aromatic and somewhat tea-like; taste sweetish, then slightly bitter.

"*Powdered Trifolium.*—Brownish red to greenish red; numerous long, sharp-pointed unicellular non-glandular hairs with thick, non-lignified walls, the latter somewhat roughened by slight centrifugal projections; smooth, nearly spheroidal pollen grains from 0.020 to 0.048 mm. in diameter; fragments of epidermis with stomata the latter from 0.013 to 0.023 mm. in length; fragments of corolla tissue composed of closely packed polygonal cells, each cell filled with a rhombohedron of calcium oxalate, the latter up to 0.017 mm. in length." *N. F.*

The clover blossoms have been subjected to an elaborate analysis by Power and Salway (*Tr. Chem. Soc.,* 1910, xcvii, p. 231). They found a number of new phenolic substances including *pratol,* which is apparently an hydroxy-methoxy-flavone. It has a melting point of 253° C. *Pratensol* which is present in much smaller proportions has a melting point of 210° C. In addition they found three glucosides, *trifolin, isotrifolin* and one, unnamed, that yielded quercetin on hydrolysis.

Uses.—Clover was at one time attributed with alterative and anti-spasmodic properties and used in *whooping-cough* and *scrofula.* It has also been used in the form of ointments and local application to *ulcers.* It also enters into the composition of some anti-asthmatic cigarettes. There is, however, no sufficient reason to suspect it of any medicinal virtue.

TRILLIUM. N. F.

TRILLIUM Trill. [Beth Root]

"Trillium consists of the dried rhizome and root of *Trillium erectum* Linné and other species of *Trillium* (Fam. *Lilaceæ*). Trillium contains not more than 2 per cent. of foreign organic matter." *N. F.*

Beth Root; Birth Root; Wake Robin.

The trilliums are attractive native lilies easily recognized by their stout simple stem which bears at the summit a whorl of three broadly ovate leaves and a large terminal flower. The flower which appears in late spring, in the official species, is composed of three herbaceous sepals and three larger ovate petals usually of a brownish purple color. The fruit is a three-celled, six-angled red berry.

The commercial supplies of this drug are obtained chiefly from North Carolina, Virginia, Indiana and Missouri.

Description and Physical Properties.—"*Unground Trillium.*—Rhizome oblique, globular, oblong or obconical, truncate below, terminated at the top by a small bud surrounded by a sheath of scarious leaf bases, annulated by leaf scars and fissured by stem scars; from 0.6 to 5 cm. in length and from 1 to 3 cm. in width, more or less compressed laterally; rootlet scars in several concentric rows on the under side in the upper portions; externally yellowish to reddish brown; internally of a pale yellow; fracture somewhat uneven with a hard and close texture or a more or less spongy appearance. Odor distinct; taste bitter and acrid with a sensation of warmth in the throat, and when chewed causing an increased flow of saliva.

"*Powdered Trillium.*—Pale yellowish white; consisting chiefly of fragments composed of parenchyma some of which are elongated and contain raphides of calcium oxalate up to 0.225 mm. in length, others being nearly isodiametric, more or less thin-walled and containing mostly simple, nearly spheroidal altered or unaltered starch grains, the latter up to 0.020 mm. in diameter; fragments of epidermal tissue composed of cells with reddish brown porous walls; tracheæ with spiral or reticulate markings." *N.F.*

Reid (*A. J. P.,* 1892, p. 67) found in trillium 4.86 per cent. of a saponin, also an acid crystalline principle which gave a purplish brown reaction with sulphuric acid and a light green with sulphuric acid and potassium dichromate. Prendergast (*Am. Drug.*, Nov., 1886) believes that there is present a glucoside similar to convallamarin. The drug also contains volatile oil and an astringent principle, probably a tannin.

Uses.—The term birthroot appears to have been applied to this substance by the early settlers because of the fact that the American Indians used it as an aid to parturition. From this aboriginal use the early settlers came to employ the drug in the treatment of various uterine disorders, as *metrorrhagia* and *menorrhagia*. It is also employed in the treatment of various *hemorrhages* both locally and internally, and as an astringent in *diarrhea*. It is today, however, almost never employed except as an ingredient of the compound elixir of viburnum.

Dose, one-half to one drachm (2–4 Gm.).

Off. Prep.—Elixir Viburni Opuli Compositum, *N. F.;* Fluidextractum Trillii, *N. F.*

TRINITROPHENOL. U. S. (Br.)

TRINITROPHENOL Trinitrophen. [Picric Acid]

"$C_6H_2(OH)(NO_2)_3$ 1:2:4:6." *U. S.* "Picric Acid may be obtained by the action of nitric acid and sulphuric acid on phenol, and contains not less than 99 per cent. of tri-nitrophenol, $C_6H_2(NO_2)_3OH$." *Br.*

Acidum Picricum, *Br.;* Carbazotic Acid; Nitrophenic Acid, Acide Picrique, *Fr. Cod.;* Acide Carbazotique, *Fr.;* Pikrinsaüre, Bittersaüre, *G.*

Trinitrophenol is obtained by the action of nitric acid on indigo, silk, leather, wool, aloes, benzoin, Australian gum, and other substances, or, as the name indicates, from phenol (carbolic acid). It may be cheaply prepared by adding crude carbolic acid, impure phenol gradually to strong nitric acid and heating, when, on standing, the picric acid will crystallize out; but in practice it is now almost always made by dissolving crystallized phenol in strong sulphuric acid, and adding either nitric acid or sodium nitrate to the resultant phenolsulphonic acid. The reaction is as follows:

$$C_6H_5OH + H_2SO_4 = C_6H_4OH.HSO_3 + H_2O$$

$$C_6H_4OH.HSO_3 + 3HNO_3 = C_6H_2OH(NO_2)_3 + H_2SO_4 + 2H_2O$$

Its salts crystallize readily, and explode when heated. The potassium salt is so sparingly soluble that an alcoholic solution of the acid has been used as a test for this alkali. It is largely used in dyeing, producing magnificent yellow colors, and, in connection with indigo or Prussian blue, different shades of green. The salts which picric acid forms with potassium and sodium are yellow and bitter, and are much used in the arts. They are, however, violent explosives, and as such have produced very serious consequences. Picric acid itself is also a powerful explosive which is used in modern warfare, not as a propellant, but as the exploding charge in shells, a detonator being necessary to explode it. It was first used extensively during the Boer War under the name of *Lyddite.* A saturated aqueous solution of picric acid is a very delicate test for albumin. (See *Esbach's Reagent,* Part III.) *Ammonium picrate* is universally preferred for internal use. It crystallizes in rhombic scales, which are somewhat more soluble than the corresponding potassium salt.

Description and Physical Properties.—" Pale yellow, rhombic prisms or scales. It is odorless and has an intensely bitter taste. *Caution—Trinitrophenol explodes when heated rapidly or when subjected to percussion.* For safety in transportation Trinitrophenol is usually mixed with from 10 to 20 per cent. of water. Before applying the tests described below, dry the Trinitrophenol to constant weight over sulphuric acid. One Gm. of Trinitrophenol is soluble in 78 cc. of water, 12 cc. of alcohol, 35 cc. of chloroform, 65 cc. of ether, and in 10 cc. of benzene, at 25° C. One Gm. is soluble in 15 cc. of boiling water.

" Trinitrophenol melts between 121° and 123° C. An aqueous solution of Trinitrophenol is acid to litmus paper. An aqueous solution of Trinitrophenol (1 in 100) has a yellow color, which becomes more intense on the addition of alkalies, and red on the addition of ammonium sulphide T.S. or a solution of an alkaline cyanide. An aqueous solution of Trinitrophenol is precipitated by solutions of most alkaline salts.

" Add 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of Trinitrophenol (1 in 100): the liquid does not at once become opalescent (*sulphate*). Dissolve 2 Gm. of Trinitrophenol in 50 cc. of benzene, collect the insoluble residue, if any, on a small counterpoised filter, or in a Gooch crucible with an asbestos layer, which has been dried at 100° C. and weighed, and wash the residue and filter with benzene until the washings are colorless: the residue, dried at 100° C., does not exceed 0.2 per cent.

" Preserve in well-stoppered bottles, in a cool place, remote from fire." *U. S.*

" Bright yellow crystalline powder. Inodorous; taste very bitter. Soluble in 90 parts of *water,* and in 10 parts of *alcohol* (90 per cent.), forming intensely yellow solutions which stain the skin yellow. Melting point 122° C. 2 grammes dissolved in hot *water* require for neutralisation 17.3 millilitres of *N/2 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator." *Br.*

Uses.—Trinitrophenol is germicidal, astringent, and apparently stimulates epithelial growth. According to Ehrenfried (*J. A. M. A.*, 1911, lvi, 412), a saturated aqueous solution (1.2 per cent.) destroys the *Bacillus pyocyaneus* in less than one minute and the *Staphylococcus pyogenes aureus* in two minutes. In the experiments of Schamberg and Kolmer (*L. L.*, 1911, ii, p. 1397) it showed itself four times as active as phenol while Tidy (*L. L.*, 1915, clxxxix, 604) gives its phenol coefficient as 6.

Internally trinitrophenol is comparatively feeble in its effects upon the system. It is absorbed probably as a sodium salt and eliminated chiefly through the urine to which it imparts an intense yellow color. After large doses the skin and mucous membranes are also stained yellow. In toxic quantities it causes in the lower animals destruction of the red blood corpuscles, but this effect has not been reported in man. The symptoms of poisoning as observed in human beings have been vomiting, diarrhea (the matters ejected being stained yellow), strangury and often anuria; in severe cases stupor with convulsions followed by collapse have also been noted. A very common symptom, even after not extremely large doses, is itching of the skin frequently associated with an eczematous eruption. Ehrenfried states that 15 to 30 grains are sufficient to cause toxic symptoms. It should be remembered that the drug may be absorbed after its local application in sufficient quantities to produce constitutional effects.

Internally picric acid has been used in the treatment of *trichinosis* and *malaria,* but is probably without any value. It is capable of destroying intestinal parasites, either *tapeworm* or *roundworm,* but has no advantage over other vermifuges. The practical value of trinitrophenol in medicine is as a local agent. It is strongly recommended for the sterilization of the skin preceding operations (see Farr, *Annals of Surg.,* 1921, lxxiii, p. 13). While by some used as an antiseptic dressing for superficial *wounds,* it is especially prized in *burns* of the first and second degree and is also useful for its astringent and antiseptic action in *ulcers* with free discharge. Wilcox (*Archives of Pediatrics,* 1913, xxx) recommends it very highly in the treatment of various skin diseases, especially acute *eczema, intertrigo,* and *herpes labialis.* In local *hyperidrosis,* especially of the feet, it has long been recognized as a standard remedy. Picric acid is also highly recommended by a number of ophthalmologists in the treatment of *injuries of the cornea,* due to caustic agents, such as quick-lime and the mineral acids. It has also been employed in simple *conjunctivitis* and in *trachoma.* For the latter purpose Ohlemann (*Wochens. f. Ther. u. Hyg. d. Auges,* 1910, p. 103) recommends a 2 per cent. ointment which is applied directly to the lid, after previous cocainization if necessary.

For surgical purposes from one-half to one per cent. is generally used. In skin diseases the aqueous solution may be either painted over the lesion or sometimes gauze moistened with the solution applied. In sweating feet a dusting powder containing 2 per cent. of picric acid with talc is sometimes used. The great drawback of the remedy is its powerful staining properties.

In skin diseases when the epiderm is unbroken it may be desirable to use stronger solutions in which case a hydro-alcoholic menstruum is employed.

Picric acid poisoning is quite common among workers engaged in the manufacturing of high explosives (see Hamilton, *J. A. M. A.,* 1917, lxviii, 1447). In some cases this is manifested by dermatitis, often quite severe and resistant to treatment. The inflammation of the skin in these cases bears a strong resemblance to that seen in ivy poisoning and at times is accompanied with marked constitutional disturbances, such as headache, loss of appetite, nose bleed, and fever. There is in many of these cases more or less leukocytosis. In other patients the symptoms are chiefly gastro-intestinal; abdominal cramps, diarrhea, vomiting and headache being the most common manifestations. The inhalation of the dust by these workers produces a bronchitis accompanied with a dry hacking cough, often with expectoration of blood, and signs of irritation of the throat.

Dose, one-half to one grain (0.032–0.065 Gm.).

TRITICUM. N. F. (Br.)

TRITICUM Tritic. [Couch Grass, Dog Grass]

"Triticum consists of the dried rhizome and roots of *Agropyron repens* (Linné) Beauvois (Fam. *Gramineæ*). Triticum contains not more than 2 per cent. of foreign organic matter and yields not more than 3 per cent. of acid-insoluble ash." *N. F.*

"Couch Grass is the dried rhizome of Agropyron repens, *Beauv.,* freed from remains of leaves and rootlets." *Br.*

Agropyrum, *Br.;* Rhizoma Graminis; Radix Graminis; Dog Grass, Quick-grass, Quitch, Twitch-grass, Witch-grass, Quickens; Chiendent Officinal, Petit chiendent, *Fr. Cod.;* Queckenwurzel, Grasswurzel, *G.;* Grama (Rizoma de), *Sp.*

This grass, originally a native of Europe, now abounds in meadows and cultivated grounds in the northern United States, where it is often very troublesome as a weed. It is specifically characterized by its creeping rootstock, the leaves being flat, thin and finely veined, and the flowering glumes being glabrous or scabrous. It is probable that the rhizomes of a number of other grasses share the medicinal properties of *Agropyron repens.* Of these the Scotch or Bermuda grass, *Capriola Dactylon* (L.) Kuntze, is probably as effective as the official species.

Much spurious triticum has appeared upon the market recently. Most of it can be readily distinguished from the official drug by the presence of abundant starch in the spurious article.

The commercial supplies of triticum come largely from England and Germany.

Description and Physical Properties.—"*Unground Triticum.*—Rhizome; usually in pieces from 4 to 12 mm. in length and from 1 to 2.5 mm. in diameter; externally light yellow or yellowish brown, longitudinally furrowed, smooth, lustrous, nodes with circular leaf-scars, a few root-scars and occasional slender roots; fracture tough, fibrous; internally lemon-yellow and with a large, hollow pith. Roots filiform, irregularly branching, attaining a length of about 5 cm. and not more than 0.5 mm. in thickness, light brown or yellowish brown, frequently covered with long root hairs. Odor slight, aromatic; taste sweetish.

"*Structure.*—A single layer of strongly lignified epidermal cells showing in surface view characteristic twin-cells having strongly silicified walls and giving a ball and socket appearance; a hypodermis of from 3 to 6 rows of cells with strongly lignified walls; a cortex of from 10 to 16 rows of thin-walled parenchyma cells, occasionally with nearly spherical starch grains up to 0.015 mm. in diameter, or with irregular masses of a more or less soluble carbohydrate; among the parenchyma cells and near the hypodermis occur small, widely separated fibro-vascular bundles, each with a closed sheath of fibers; an endodermis, the lateral and inner walls of the cells moderately thickened, strongly lignified and somewhat porous; several layers of fibers immediately inside the endodermal ring, in which are imbedded an interrupted circle of about 10 to 12 collateral fibro-vascular bundles having large tracheæ; adjoining these are usually 8 to 10 rows of parenchyma cells with a few fibrovascular bundles and a pith in which the parenchyma cells are more or less broken or absent.

"*Powdered Triticum.*—Light yellowish; consisting of irregular, lignified fragments; numerous fragments showing tracheæ with annular or spiral thickenings or marked with simple pores and associated with long, narrow, rather thin-walled, strongly lignified sclerenchymatous fibers; fragments of epidermis made up of cells rectangular in outline, the longer walls considerably thickened, strongly lignified and marked with numerous transverse pores; ends of epidermal cells usually separated from each other by a very narrow cell with thin walls and few pores, numerous fragments of parenchyma rectangular in outline and with thin, porous walls." *N. F.*

"Rhizome pale yellow, rigid, from two to two and a half millimetres in diameter, usually in pieces from three to six millimetres long. Strongly furrowed longitudinally, hollow except at the nodes. Contains no starch. No odor; taste slightly sweet." *Br.*

The morphology of triticum has been described by Holm (*M. R.*, xix, p. 65). The chief adulterant for Triticum is the rhizomes and roots of *Cynodon Dactylon* L. (*Capriola Dactylon* (L.) Kze.), commonly known as *Bermuda-*, or *Bahama-Grass*, a native of Europe but naturalized in America. For a detailed distinction between this article and triticum, see Zufall, *J. A. Ph. A.*, 1919, p. 472. Small (*A. J. P.*, 1919, xci, 685) asserts that there is practically no true triticum on the market; the commercial article being sold for it is practically all Bermuda grass.

The Austrian Pharmacopœia has a requirement of not less than 30 per cent. of aqueous extractive for this drug.

Triticum contains dextrose and levulose to the extent of some 2 or 3 per cent., also a dextrorotatory sugar of undetermined identity, gum and inosite. According to Alsberg, Viehover and Yewey (*J. A. Ph. A.*, 1919, 469) triticum contains two glucosides, one of which yields vanillin on hydrolysis, also a carbohydrate resembling inulin which has been named *triticin.* The ash contains much silica.

Uses.—Triticum is never exhibited for the purpose of affecting the general system, but only for its influence upon the genito-urinary organs. It is much used by some surgeons in *irritable bladder,* and also in *cystitis.* It is one of the least stimulant of the remedies of its class, and may be employed very freely. In Europe its decoction is said to be used to a considerable extent as a diluent and slightly nutritious drink.

Dose, from two to four drachms (4–8 Gm.) or more.

Off. Prep.—Fluidextractum Tritici, *N. F.;* Decoctum Agropyri, *Br.;* Extractum Agropyri Liquidum, *Br.;* Elixir Sabal et Santali Compositum, *N. F.*

TRITURATIONES. U. S.

TRITURATIONS

"Unless otherwise directed, Triturations are to be prepared according to the following formula: The Substance, 10 Gm.; Lactose, in moderately fine powder, 90 Gm.; to make 100 Gm. Weigh the medicinal substance and the lactose separately; then place the substance, previously reduced, if necessary, to a moderately fine powder, in a mortar. Add about an equal measure of lactose, mix well by means of a spatula, and triturate the powders thoroughly together. Then add fresh portions of the lactose, from time to time, until the whole is added, and continue the trituration after each addition until the substance is intimately mixed with the lactose and reduced to a fine powder." *U. S.*

This general formula has been introduced into the Pharmacopœia in order that a definite and uniform method be authorized of making a class of powders which has come into use in various sections of our country. While the necessity of giving recognition to the class may be questioned by many, the importance of securing uniformity in composition is evident.

TROCHISCI.

TROCHES

Lozenges; Pastilli, Rotulae, *P. G.;* Pastillen, Plätzchen, *G.;* Pastiglie, *It.*

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities and which are destitute of any very disagreeable flavor.

Lozenges were formerly much more used and more skilfully prepared in Europe than in this country, but at present those manufactured here are fully equal to the imported lozenges. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues*. A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now dusted with sugar and starch, and the mass is divided into small cakes by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in boxes. Lozenges may be prepared from almost any medicine which it is advisable to administer in this form. The following typical formula may be found useful.

Take citric acid, in powder, a drachm; powdered sugar eight ounces; oil of lemon twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. Lozenges are sometimes made by saturating blank lozenges with aromatic spirits. Black-currant paste has come into use largely as a basis for troches because of its official recognition in the British Pharmacopœia. For formulas for lozenges with current paste basis, see *U. S. D.*, 19th edition, page 1297.

Lozenges of a cylindrical shape are extensively used, having a basis of licorice, gum, and sugar, and the manufacture of these is now an important industry.

The Br. Pharmacopœia, 1914, adopted four bases for lozenges, as follows: fruit basis, rose basis, simple basis, and tolu basis. It will be noticed that in the British formulas the quantity of active ingredients for each lozenge is stated and the kind of basis indicated. This is done merely to avoid repetition.

PREPARATION WITH FRUIT BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Mix it with 6.5 grammes of Tragacanth and 26 grammes of Refined Sugar, both in fine powder. Add sufficient of the black-currant paste of commerce to produce 650 grammes, beat into a uniform mass, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH ROSE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Treat it as described under 'Preparation with Simple Basis,' previously mixing with the Refined Sugar 0.025 millilitre of Oil of Rose." *Br.*

PREPARATION WITH SIMPLE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge, mix it with 496 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Make the mixture into a paste with 35 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH TOLU BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve such salts of alkaloids as may be ordered in 10 millilitres of Distilled Water; mix the solution with 482 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Incorporate 10 millilitres of Tincture of Balsam of Tolu, and any other drugs ordered for the lozenges. Make into a paste with 35.5 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water; divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

TROCHISCUS ACIDI BENZOICI. Br.

BENZOIC ACID LOZENGE

Tablettes de l'Acide Benzoique, *Fr.;* Benzoesäurepastillen, *G.*

"Benzoic Acid, 0.03 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

This is a stimulant and antiseptic lozenge useful in *chronic pharyngitis,* and other passive congestions of the buccal cavity.

TROCHISCUS ACIDI CARBOLICI. Br.

PHENOL LOZENGE

Tablettes de l'Acide Phénique, *Fr.;* Phenolpastillen, *G.*

"Phenol, in powder, 15 *grammes;* Refined Sugar, in powder, 500 *grammes;* Gum Acacia, in powder, 45 *grammes;* Tragacanth, in powder, 15 *grammes;* Lemon Juice, 45 *millilitres.* Mix. Divide into five hundred lozenges. Dry them in a hot-air chamber at a moderate temperature. Each lozenge contains 0.03 gramme of Phenol, or approximately one-half grain. It is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This lozenge affords an excellent means of obtaining the antiseptic and local anodyne effect of phenol in *acute pharyngitis, stomatitis,* and similar infections of the mouth and throat.

TROCHISCI ACIDI TANNICI. U. S. (Br.)

TROCHES OF TANNIC ACID Troch. Acid. Tann.

Trochiscus Acidi Tannici, *Br.;* Tannic Acid Lozenge; Tannin Lozenges; Tablettes de Tannin, *Fr.;* Tanninpastillen, *G.*

"Tannic Acid, 6 Gm.; Sucrose, in fine powder, 65 Gm.; Tragacanth, in very fine powder, 2 Gm.; Orange Flower Water, a sufficient quantity to make 100 troches. Triturate the powders until they are thoroughly mixed, form a mass with orange flower water, and divide it into 100 troches." *U. S.*

"Tannic Acid, 0.03 *gramme.* Mix with the *Tolu Basis* to form a Lozenge." *Br.* (See above.)

These are useful in *relaxation of the uvula,* and in *chronic angina,* being allowed slowly to dissolve in the mouth. Each U. S. troche contains about one grain (0.065 Gm.) of the acid; the Br. about half a grain (0.032 Gm.).

TROCHISCI AMMONII CHLORIDI. U. S.

TROCHES OF AMMONIUM CHLORIDE Troch. Ammon. Chlor.

Tablettes de Chlorhydrate d'Ammoniaque, *Fr.;* Chlorammoniumpastillen, *G.*

"Ammonium Chloride, in fine powder, 10 Gm.; Extract of Glycyrrhiza, in fine powder, 20 Gm.; Tragacanth, in very fine powder, 2 Gm.; Sucrose, in fine powder, 40 Gm.; Syrup of Tolu, a sufficient quantity to make 100 troches. Triturate the powders until they are thoroughly mixed; form a mass with syrup of tolu, and divide it into 100 troches." *U. S.*

Each troche contains about one and a half grains (0.096 Gm.) of ammonium chloride.

These troches are largely used in *congested conditions of the pharynx and larynx.*

TROCHISCUS BISMUTHI COMPOSITUS. Br.

COMPOUND BISMUTH LOZENGE

Troches of Bismuth; Tablettes de Sous-nitrate de Bismuth, *Fr. Cod.;* Bismuthpastillen, *G.*

"Bismuth Oxycarbonate, 0.15 *gramme;* Heavy Magnesium Carbonate, 0.15 *gramme;* Precipitated Calcium Carbonate, 0.30 *gramme.* Mix with the *Rose Basis* to form a Lozenge." *Br.*

These may be used to obtain the effects of bismuth subcarbonate on the stomach, as well as of the magnesium and calcium carbonates as an antacid, two or more being administered for a dose. They may also be found useful in *chronic inflammation of the throat and esophagus.*

TROCHISCUS CATECHU. Br.

CATECHU LOZENGE

"Catechu, 0.06 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

This lozenge was introduced into the Br. Pharm., 1914. It is mildly astringent.

TROCHISCUS FERRI REDACTI. Br.

REDUCED IRON LOZENGE

Tablettes de Fer Réduit par l'Hydrogène, Tablettes de Fer, *Fr.;* Eisenpastillen, *G.*

"Reduced Iron, 0.06 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.*

From one to three of the lozenges may be taken for a dose.

TROCHISCUS GUAIACI RESINÆ. Br.

GUAIACUM RESIN LOZENGE

Tablettes de Résine de Gayac, *Fr.;* Guajakharzpastillen, *G.*

"Guaiacum Resin, 0.2 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

TROCHISCUS IPECACUANHÆ. Br.

IPECACUANHA LOZENGE

Tablettes d'Ipécacuanha, *Fr. Cod.;* Brechwurzelpastillen, *G.;* Pastiglie d'ipecacuana, *It.*

"Ipecacuanha Root, in powder, 0.015 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.*

TROCHISCUS KINO EUCALYPTI. Br.

EUCALYPTUS KINO LOZENGE

Eucalyptus Gum Lozenge, Red Gum Lozenge; Tablettes de Kino d'Eucalypte, *Fr.;* Eucalyptuskinopastillen, *G.*

"Eucalyptus Kino, 0.06 *gramme.* Mix with the *Fruit Basis* to form a lozenge." *Br.*

A similar lozenge is recognized by the N. F. (See *Trochisci Eucalypti Gummi,* Part III.)

A popular astringent lozenge used in *sore throat* and relaxed conditions of the mouth.

TROCHISCUS KRAMERIÆ. Br.

KRAMERIA LOZENGE

Krameria Lozenge, Rhatany Lozenge; Tablettes de Ratanhia, *Fr.;* Ratanhiapastillen, *G.*

"Extract of Krameria, 0.06 *grdmme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

TROCHISCUS KRAMERIÆ ET COCAINÆ. Br.

KRAMERIA AND COCAINE LOZENGE

Rhatany and Cocaine Lozenge; Tablettes de Ratanhia et de Cocaine, *Fr.;* Ratanhia- und Cocain-pastillen, *G.*

"Extract of Krameria, 0.060 *gramme;* Cocaine Hydrochloride, 0.003 *gramme.* Mix with the *Fruit Basis* to form a Lozenge. This Lozenge contains 0.003 gramme of Cocaine Hydrochloride, or approximately $^1/_{20}$ grain." *Br.*

TROCHISCUS MORPHINÆ. Br.

MORPHINE LOZENGE

Tablettes de Chlorhydrate de Morphine, Tablettes de Morphine, *Fr.;* Morphinpastillen, *G.*

"Morphine Hydrochloride, 0.002 *gramme.* Mix with the *Tolu Basis* to form a Lozenge. This Lozenge contains 0.002 gramme of Morphine Hydrochloride, or approximately $^1/_{32}$ grain." *Br.*

This is an undesirable preparation, as the local action of morphine is insignificant. Any sedative effect in *cough* will be due to the systemic absorption of the drug.

TROCHISCUS MORPHINÆ ET IPECACUANHÆ. Br.

MORPHINE AND IPECACUANHA LOZENGE

Tablettes de Morphine et d'Ipécacuanha, *Fr.;* Morphinpastillen mit Brechwurzel; Morphin und Brechwurzel-pastillen, *G.*

"Morphine Hydrochloride, 0.002 *gramme;* Ipecacuanha Root, in powder, 0.006 *gramme.* Mix with the *Tolu Basis* to form a Lozenge. This Lozenge contains 0.002 gramme of Morphine Hydrochloride, or approximately 1/32 grain." *Br.*

This tablet is used as an expectorant. Its effects are the same as would be those of its ingredients if administered in solution. Each lozenge contains one-thirtieth of a grain (0.002 Gm.) of morphine salt, and one-tenth of a grain (0.006 Gm.) of ipecacuanha.

TROCHISCUS POTASSII CHLORATIS. Br.

TROCHES OF POTASSIUM CHLORATE Troch. Pot. Chlorat.

Trochisci Potassii Chloratis, *U. S. IX;* Potassium Chlorate Lozenge, Chlorate of Potash Lozenges; Tablettes de Chlorate de Potasse, *Fr.;* Kaliumchloratpastillen, Pastillen von Chlorsaurem Kali, *G.;* Pastiglie di clorato di potassio, *It.;* Tabletas de clorato potasico, *Sp.*

These troches have been dropped at the last revision of the U. S. The formula of the U. S. IX was "Potassium Chlorate, in fine powder, *fifteen grammes;* Sugar, in fine powder, *sixty grammes;* Tragacanth, in fine powder, *three grammes;* Water, *a sufficient quantity,* to make *one hundred troches.* Mix the sugar with the tragacanth by trituration in a mortar; then transfer the mixture to a sheet of paper, and by means of a bone or wooden spatula mix it with the potassium chlorate, being careful to avoid unnecessary trituration or pressure, which might cause the mixture to ignite or explode. Lastly form a mass with water and divide it into *one hundred troches." U. S. IX.*

"Potassium Chlorate, 0.2 *gramme.* Mix with the *Rose Basis* to form a Lozenge." *Br.*

These lozenges are employed as mildly stimulant and astringent in cases of *sore throat,* although in commercial usage the official troches are almost entirely replaced by compressed tablets of potassium chlorate.

TROCHISCUS SANTONINI. Br.

SANTONIN LOZENGE

Trochisci Santonini, *U. S. VIII;* Troches of Santonin; Tablettes de Santonine, *Fr. Cod.;* Pastilli Santonini, *P. G.;* Santoninpastillen, *G.;* Pastiglie de santonina, *It.;* Tabletas de santonina, *Sp.*

"Santonin, 0.06 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.* (See p. 1168.)

Troches of santonin are also official in the N. F. V (see Part III).

The N. F. process is faulty in the direction that the santonin be in fine powder. The longer the absorption of santonin is delayed in the intestines the more prolonged and consequently the more effective is its vermicidal influence. As soon as it is absorbed it ceases to act upon the worm, and becomes a more or less deleterious substance in the system. A dose of santonin in crystals which is not poisonous may become somewhat toxic when given in fine powder. The proportion of crystals in the lozenge mass (2½ per cent.) is not sufficient to prevent the formation of a good lozenge from a pharmaceutical point of view. The National Formulary lozenge contains about half a grain (0.032 Gm.) of santonin. The Br. formula calls for about one grain (0.065 Gm.).

Dose, for an adult, of the Br. lozenge, from one to three lozenges.

TROCHISCUS SULPHURIS. Br.

SULPHUR LOZENGE

Tablettes de Soufre, *Fr. Cod.;* Schwefelpastillen, *G.*

"Precipitated Sulphur, 150 *grammes;* Acid Potassium Tartrate, in powder, 30 *grammes;* Refined Sugar, in powder, 275 *grammes;* Gum Acacia, in powder, 30 *grammes;* Tincture of Orange, 30 *millilitres;* Mucilage of Gum Acacia, 30 *millilitres.* Mix the Tincture of Orange with the powders; add the Mucilage of Gum Acacia to form a suitable mass. Divide into five hundred Lozenges. Dry them in a hot-air chamber at a moderate temperature. Each Lozenge contains 0.3 gramme of Precipitated Sulphur, or approximately 5 grains." *Br.*

Dose, from one to six lozenges. (See *Sulphur Sublimatum.*)

TURPETHUM. Br.

TURPETH

"Turpeth is the dried root and stem of Ipomœa Turpethum, *R.Br.*" *Br.*

Radix Turpethi; Turpeth Root; Indian Jalap; Trivrit; Nisoth, Turbith, *Fr.;* Turbit (Raiz de), *Sp.*

Ipomœa Turpethum (*Operculina Turpethum* (L.) Peter) (Fam. *Convolvulaceæ*) is a convolvulaceous plant which is found throughout India, the Malay Archipelago, China, Ceylon, Australia, and is occasionally cultivated in botanical gardens as an ornamental plant. There are two varieties, viz., *Sveta* or white turpeth, and *Kirshna* or black turpeth, the former being preferred as a mild cathartic. The black variety is said to be a powerful drastic.

According to Mérat and De Lens, the root itself formerly came into commerce, but at present turpeth consists of the root and stem of the plant cut into short lengths, usually from 1.5 to 5 cm. in diameter; the central woody portion is often removed by splitting the bark on one side. The pieces are cylindrical, somewhat twisted and externally of a dull gray color. A transverse section shows a porous central wood surrounded by a broad cortical portion, containing yellowish-brown resin cells, laticiferous vessels and crystals of calcium oxalate. The fracture is short in the cortex and fibrous in the central portion. The drug has a faint odor and a nauseous taste, which is perceptible only after it has been some time in the mouth.

"In cylindrical pieces of varying length, from one to five centimetres wide, often split on one side and deprived of the central portion; longitudinally furrowed; dull grey or brown. Fracture of the bark short, of the wood fibrous; internally usually pale grey. In transverse section, a porous wood surrounded by a thick bark in which abnormal wood-bundles are frequently present. Slight odor; taste nauseous, slowly developed." *Br.*

Turpeth contains a yellow coloring matter and a small amount of volatile oil but its important medicinal effect depends upon its resin of which it contains about 5 or 10 per cent. A part of this, which is soluble in ether, seems to be of complex nature; it has been called *turpethein* but is probably very similar to the resin known as convolvulin. The principal resin, however, is that known as *turpethin.* This does not dissolve in ether but does in alcohol, to which it imparts a brown color not removable by animal charcoal; it has been given the formula $C_{34}H_{56}O_{16}$. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by, and afterwards boiled with, water, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and is fusible at 182.2° C. It is inflammable, burning with a smoky flame and emitting irritant vapors. With strong bases it acts like jalapin, takes up water, and is transformed into a soluble acid, *turpethic acid,* $C_{34}H_{60}O_{18}$, while with dilute acids it is decomposed into *turpetholic acid,* $C_{16}H_{32}O_4$, and glucose. (*J. P. C.,* 4e sér., i, 236.)

Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action.

Dose, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Tinctura Jalapæ Composita, *Br.*

ULMUS. U. S.

ELM [Elm Bark, Slippery Elm]

"Elm is the dried inner bark of *Ulmus fulva* Michaux (Fam. *Ulmaceæ*)." *U. S.*

Red Elm, Moose-elm, Indian Elm; Cortex Ulmi Interior, Ulmi Cortex; Orme Fauve, Ecorce d'Orme, *Fr.;* Ulmenrinde, Rüsterrinde, *G.*

The *slippery elm* (*Ulmus fulva*) is a lofty tree, fifty or sixty feet in height, with a trunk fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are petiolate, oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which are apetalous, appear before the leaves, are sessile, and in clusters at the extremities of the young shoots. The clusters of flowers are surrounded by scales, which are downy like the buds. The calyx is also downy. The stamens are five, short, and of a pale rose color. The fruit is a membranaceous samara, enclosing in the middle one round seed, destitute of fringe.

Ulmus fulva is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Allegheny Mountains. It extends westward to the Dakotas and northward to western Quebec and Lake Huron. It flourishes in open, elevated situations, and requires a firm, dry soil. From the *white elm* (*U. americana* L.) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark, separated from the cortex, is the part used. Elm bark is gathered in the spring, deprived of the cork and part of the cortex, sawed into oblong pieces and dried. It is packed in bundles which are bound at each end with wire. Large quantities are collected in the Lower Peninsula of Michigan.

Fremontia californica Torr., or *California Slippery Elm,* is not botanically allied to *Ulmus fulva;* its bark is said, however, to have the same properties as slippery elm bark, and to be used for a similar purpose.

Description and Physical Properties.—"*Unground Elm.*—Usually broad, flat, oblong pieces, from 1 to 4 mm. in thickness; outer surface pale brown, roughened by longitudinal striæ and partially detached bundles of bast-fibers and with occasional thin, dark brown patches of adhering cork; inner surface light yellowish-brown, finely striate, fracture fibrous, with projections of fine bast-bundles; odor distinctive; taste mucilaginous.

"*Structure.*—Bast-fibers in small bundles or individual and arranged in numerous tangential rows alternating with rows of mucilage cells, the latter from 0.1 to 0.4 mm. in diameter; medullary rays 4 to 6 cells wide and bearing starch; sieve associated with parenchyma cells, the latter containing starch or prismatic monoclinic crystals or twin crystals of calcium oxalate, the crystal cells frequently so elongated and the crystals superimposed as to form short, non-lignified crystal-fibers.

"*Powdered Elm.*—Very light brown; bast-fibers numerous, very long, usually broken, up to 0.025 mm. in diameter, thick-walled, unlignified or with only a thin outer sheath of the wall lignified; calcium oxalate prisms from 0.010 to 0.035 mm. in length; starch grains spheroidal or polygonal, usually from 0.003 to 0.015 mm.

in diameter, occasionally up to 0.25 mm. in length; mucilage fragments numerous, frequently lamellated; brown-walled cork cells few or absent.

"Macerate 1 Gm. of finely powdered Elm with 40 cc. of water for one hour: the mixture is of a thick mucilaginous consistence and of a light brown color." *U. S.*

Ulmus abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of lead acetate and subacetate, but not by alcohol. It contains a variety of tannin which colors iron solutions green, in amount about 6.5 per cent. according to Rink, or, according to Davy, a little less than 3 per cent.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odor of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kinds, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to state. Ground elm bark is said to be adulterated, usually with substances containing starch. Roberts found commercial specimens which possessed considerable of a brownish outer bark still adhering to them. One specimen was partly mouldy and had considerable adhering wood. (*Proc. Penn. Ph. Assoc.,* 1913, p. 85.) The following test, devised by Geo. M. Beringer, seems to have practical value: Ten grains of ground or pulverized elm bark, thoroughly shaken with one fluidounce of water, will, if pure and of good quality, in fifteen minutes form a thick jelly-like mass of a fawn color.

Elm bark has the property of preserving fatty substances from rancidity, a fact known to the Indians, who prepared bear's fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat.

Uses.—The elm bark is an excellent demulcent, formerly largely employed, but today used chiefly in the form of lozenges to relieve *irritation of the pharynx.* A warm infusion is a popular folk remedy in the treatment of *diarrheas, coughs,* etc. This is made by stirring an ounce of the powdered bark in a pint of hot water with which it forms a mucilage that may be drunk *ad libitum.*

It is commonly used as a drink in the form of infusion. (See *Mucilago Ulmi.*) The powder may be used stirred in hot water, with which it forms a mucilage more or less thick according to the proportion added. The bark also serves as an emollient application in cases of *external inflammation.* For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. McDowell, of Virginia, recommended slippery elm bark for the dilatation of *fistulas* and *strictures* (*Med. Examiner,* i, 244); subsequently H. R. Storer, of Boston, used it advantageously for *dilating the os uteri* (*B. M. S. J.,* liii, 300), and A. Abbe, of the same place, succeeded in curing with it a case of *stricture of the rectum* (*B. M. S. J.,* liv, 349).

Off. Prep.—Trochisci Ulmi, *N. F.*

UNGUENTA.

OINTMENTS

Salves; Pomati; Pommades, Onguents, *Fr.;* Salben, *G.;* Pomatas, Unguentos, *It.;* Pomadas, Unguentos, *Sp.*

These are fatty substances, softer than cerates, of such a consistence that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with simple ointment, hydrous wool-fat, lard, or petrolatum, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division before being incorporated with the unctuous matter. If soluble in water or in alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. On the large scale manufacturers frequently make use of "paint mills" for making this class of preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with water or alcohol, according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, elm bark or with poplar buds, as recommended by Deschamps; but care should be taken that there be no therapeutic objection to the admixture.

It has been proposed to substitute glycerin for oils and fats in the preparation of ointments, either wholly or in part; but ointments thus prepared are altogether unfit for application by inunction, as a portion of the glycerin remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter, and in some skin diseases glycerin in an ointment would be positively injurious, due to its dehydrating properties which make it irritating.

Linnett (*Pract. Drug.,* 1917, p. 34) finds hydrogenated oil an ideal ointment base, being a good carrier, quickly absorbed, practically non-rancid, and economical. He gives several formulas for ointments with this base. A large number of combinations of oleates, fats or glycerin with various other substances have been recommended as ointment bases. It is extremely doubtful, however, whether any of these possess real superiority to the official preparations.

The cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance to be strictly entitled to the name of ointment which is not of such a consistence as to adapt it to application to the skin by friction or inunction.

Ointments should be dispensed in glass, porcelain, or queensware pots or jars, or, if for temporary use, in tight wooden boxes. A very convenient method of dispensing soft ointments is in compressible tubes. These tubes are similar to those used for holding artists' colors, and have the advantage of shielding the ointment from the oxidizing action of the air while allowing the use of the desired quantity. Vanderkleed and Heidlberg (*Proc. P. P. A.*, 1913, p. 312) state that the only satisfactory method of determining whether or not the proper degree of subdivision has been attained is by the use of the microscope, and call attention to some of the precautionary measures which should be taken in order to obtain correct results. Their article is illustrated by numerous photographic representations of ointments of different degrees of fineness.

Uses.—The choice of base for ointments will vary according to the purpose for which the ointment is intended. We may divide the uses of ointments into three groups; (1) for influence upon the epiderm either as protectives or to retain active medicaments in contact with the skin; (2) to carry drugs into the true skin or subcutaneous tissues for antiseptic or anesthetic action; and (3) to introduce drugs into the circulation.

For the first purpose it is obvious that an ointment base is desirable which will tend to cling to the skin. For this reason those which become completely liquid at the bodily temperature are as a rule less desirable. On the other hand if the base is too stiff it will not be easily spread. Also a certain degree of stickiness is desirable. Wool-fat possesses in eminent degree a proper consistency for remaining where it is placed. If not modified with some emollient, however, it is rather difficult to spread and also has an objectionable odor. For the second purpose the base requires the power of penetrating the epiderm. It seems probable that, other things being equal, those fats which liquefy at the body temperature will be taken up by the superficial layers of the skin more readily, a view which has received some experimental confirmation. Various investigators have attempted to solve this problem experimentally. Sutton (*B. M. J.*, 1908, May 23, p. 1225) applied ointments of scarlet dye made with various bases and after a period of 3 or 4 hours excised pieces of the skin and examined them microscopically to see how deeply the stain had penetrated. He found that lard and goose grease gave the best penetration, wool-fat penetrated but slightly, although when mixed with equal parts of olive oil it gave a fair degree of penetration. Petrolatum penetrated scarcely at all unless applied with friction.

Gardiner (*B. M. J.*, 1912, i, p. 238) rubbed ointments containing various stains into the shaven skin of guinea pigs and then examined the skin microscopically to observe the depth of penetration. He found that olive oil penetrated more deeply than any substance with which he experimented, but that goose grease and lard also penetrated well. Petrolatum remained limited to the very superficial portions of the skin. Wool-fat, while it penetrated somewhat more deeply than petrolatum, was noticeably behind lard. Wild (*B. M. J.*, 1911, ii, p. 161) employed a very different method to study this subject. He rubbed pure ointment bases into the skin for a measured time and then scraped off what was left on the skin and weighed. The difference between the quantity taken and that recovered he considered to represent the amount absorbed. He found that petrolatum was absorbed practically not at all, that of lard or olive oil about 15 per cent., and of hydrous wool-fat about 20 per cent., but that the absorption of the latter was noticeably less if it was deficient in water. The question of which base is best for endermic administration of systemic drugs has been the subject of considerable discussion. It may be pointed out, however, that no one base can serve as the best for all drugs. The question of absorption from an ointment into the blood stream involves two very distinct factors; in the first place the penetration of the medicament through the skin, and secondly the partition coefficient between the solvent properties of the fatty base and the watery basis of the blood. Even if the ointment carrying the active medicament in fatty solution goes through the skin to the capillary blood vessels, it is obvious that the blood will take away more quickly from the ointment those drugs which are more soluble in water. It is probably this fact that has led to some of the contrary results by different experimenters. One, for example, using iodine will recommend a certain base, while the second investigator using salicylic acid as a test drug will reach quite the opposite conclusions. For endermic absorption each drug offers a separate problem.

UNGUENTUM. U. S.

OINTMENT Ung. [Simple Ointment]

Unguentum Adipis, *U. S.* 1860; Unguentum Simplex; Pommade simple, *Fr.*; Unguentum cereum, *P. G.*; Wachssalbe, *G.*

"Yellow Wax, 200 Gm.; Benzoinated Lard, 800 Gm.; to make about 1000 Gm. Melt the yellow wax, add the benzoinated lard, heat gently until liquefied, and stir the mixture until it congeals.

"Note.—For use in southern latitudes and during the warm season in other localities, 50

Gm. of the benzoinated lard (or more if necessary) may be replaced by an equal quantity of yellow wax." *U. S.*

Yellow wax was used in this ointment in the U. S. P., 1890, and objection was made to the color of the ointment. It has been very properly replaced by white wax and the lard is now benzoinated.

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle, it being the basis of several official ointments.

UNGUENTUM ACIDI BORICI. U. S., Br.

OINTMENT OF BORIC ACID Ung. Acid. Bor.

Boric Ointment; Pommade de l'Acide Borique, *Fr.;* Unguentum Acidi Borici, *P. G.;* Borsalbe, *G.;* Pomada de Acido Borico, *Sp.*

"Boric Acid, in fine powder, 100 Gm.; Yellow Wax, 50 Gm.; Petrolatum, 850 Gm.; to make about 1000 Gm. Melt the yellow wax, add the petrolatum, and heat gently until liquefied. Gradually add the warm liquid to the boric acid, contained in a warm mortar, triturating thoroughly, and stir the mixture until it congeals." *U. S.*

"Boric Acid, in powder, 10 *grammes;* Paraffin Ointment, white, 90 *grammes.* Melt the Paraffin Ointment; sift in the Boric Acid; stir until cold." *Br.*

Theodore Faber (*Ph. Ztg.,* 1914, p. 163) finds that boric acid in ointments may be readily and accurately estimated by the method of Jörgensen, in which it is converted into glycerin boric acid and estimated by titration with normal potassium hydroxide volumetric solution, as in the official method for estimating boric acid, the operation being carried out at a temperature sufficiently high to melt the fat, the presence of which may be disregarded.

Uses.—This ointment is widely used both as an emollient to the skin and for its protective effect on superficial *wounds* and *abrasions.* It is popularly, although with doubtful correctness, supposed to possess valuable antiseptic and healing powers. The prevalent belief that it has antiseptic properties because of the boric acid in it has no scientific support.

UNGUENTUM ACIDI SALICYLICI. Br.

SALICYLIC ACID OINTMENT

Pommade d'Acide Salicylique, *Fr.;* Salicylsalbe, *G.*

"Salicylic Acid, in powder, 2 *grammes;* Paraffin Ointment, white, 98 *grammes.* Melt the Paraffin Ointment; sift in the Salicylic Acid; stir until cold." *Br.*

According to Bourjet (*Th. M.,* 1893) salicylic acid is absorbed into the system more readily from ointments made with the true fats than from those made with a petrolatum base, but as this ointment is used chiefly for its local effect upon the epiderm, the question of its penetration is of little importance.

UNGUENTUM ACIDI TANNICI. U. S.

OINTMENT OF TANNIC ACID Ung. Acid. Tann.

Pommade d'Acide tannique, Pommade de Tannin, *Fr.;* Tanninsalbe, *G.*

"Tannic Acid, 20 Gm.; Glycerin, 20 Gm.; Ointment, 60 Gm.; to make about 100 Gm. Dissolve the tannic acid in the glycerin with the aid of a gentle heat, and mix the solution thoroughly with the ointment, avoiding the use of iron utensils." *U. S.*

Ointment of Tannic Acid was doubled in strength at the U. S. P., 1890, revision. It is an excellent application in many cases of *piles* and *prolapsus ani,* also for *flabby ulcers.*

UNGUENTUM ACONITINÆ. Br.

ACONITINE OINTMENT

Pommade d'Oléate d'Aconitine, Pommade d'Aconitine, *Fr.;* Akonitinoleatsalbe, Akonitinsalbe, *G.;* Pomada de Aconitina, *Sp.*

"Aconitine, 2 *grammes;* Oleic Acid, 16 *grammes;* Prepared Lard, 82 *grammes.* Triturate the Aconitine with the Oleic Acid, and gently warm the mixture until dissolved; add the Prepared Lard; mix. This Ointment contains 2 per cent. of Aconitine. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

For the uses of this preparation the reader is referred to the articles on *Aconitum* and *Aconitina.* Care must be taken not to apply it too freely nor to an abraded or ulcerated surface, lest it produce serious constitutional effects.

UNGUENTUM AQUÆ ROSÆ. U. S., Br.

OINTMENT OF ROSE WATER Ung. Aq. Ros.

Rose Water Ointment; Unguentum Emolliens; Galen's Cerate, Cold-cream; Cerat de Galien, Ceratum Galeni, *Fr. Cod.;* Cérat cosmétique, Crême froide, *Fr.;* Unguentum leniens, *P. G.;* Cold Cream, *G.*

"Spermaceti, 125 Gm.; White Wax, 120 Gm.; Expressed Oil of Almond, 560 Gm.; Sodium Borate, in fine powder, 5 Gm.; Stronger Rose Water, 190 Gm.; to make about 1000 Gm. Reduce the spermaceti and the white wax to fine pieces and melt them on a water bath, add the expressed oil of almond, and stir, continuing the heat until the mixture is uniformly melted. Dissolve the sodium borate in the stronger rose water warmed on a water bath to the temperature of the melted wax and fat, and add the warm solution gradually to the melted mixture, stirring it rapidly and continuously until it congeals and becomes of uniform consistence. Ointment of Rose Water must be free from rancidity. If the Ointment has been chilled, warm it slightly before attempting to incorporate other ingredients with it. Preserve in pure tin, collapsible tubes." *U. S.*

"Rose Water, 20.0 *millilitres;* White Beeswax, 18.0 *grammes;* Purified Borax, 1.0 *gramme;* Almond Oil, 61.0 *grammes;* Oil of Rose, 0.1 *millilitre.* Melt the White Beeswax in the Almond Oil; add, with constant stirring, the Borax previously dissolved in the Rose Water; add the Oil of Rose, and continue to stir until cold." *Br.*

This preparation is a white, very soft, and elegant ointment, deriving a grateful odor from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. We have found it an improvement to add oil of rose in the proportion of one drop to eight ounces, and, when made in the official quantity, to use an instrument known as the "Dover egg-beater" for giving it the desired creamy appearance. In larger amounts an ice cream churn or one of the mechanical mixing devices sold for mixing or emulsifying is well adapted for this purpose.

"Cold cream" is not recognized in the U. S. Pharmacopœia as an official synonym for ointment of rose water. This course became necessary because of the large number of unofficial ointments of varying composition popularly exploited as cold creams, and these were frequently dispensed, when physicians' prescriptions directed Ointment of Rose Water. The commercial cold creams must be made from substances which are not liable to rancidity, and paraffin oil, liquid petrolatum, white petrolatum, etc., largely form the basis of such, but the official ointment is to be preferred for use in prescriptions. W. C. Alpers furnishes the following formula for a cold cream which is more permanent than the official ointment. One hundred and fifty parts of white wax is melted in 600 parts of paraffin oil with the aid of a gentle heat; 9 parts of borax is dissolved in 240 parts of water; the two fluids are brought to a uniform temperature, not exceeding 60° C., and the aqueous solution is poured into the oily one in a continuous stream, stirring gently for a minute or two; then 1 part of oil of geranium and a little oil of rose are added while stirring, and the product while still warm is poured into jars. The cold cream so obtained is white, soft and smooth, pleasantly odorous, keeps well in the heat of summer and the cold of winter, and becomes only slightly thinner in summer.

Uses.—This ointment is a popular and valuable emollient and base. It is sometimes applied unmedicated to *chapped hands* and other irritated states of the skin. More frequently it is used as a base for more active medicaments, being highly prized not only on account of its odor but for its peculiar consistency which makes it easy to spread; a few substances are incompatible with borax and should not be combined with it. The commercial cold creams, made with petrolatum base, do not possess the therapeutic virtues and should never be substituted for ointment of rose-water.

UNGUENTUM ATROPINÆ. Br.

ATROPINE OINTMENT

Pommade d'Oléate d'Atropine, Pommade d'Atropine, *Fr.;* Atropinoleatsalbe, Atropinsalbe, *G.*

"Atropine, 2 *grammes;* Oleic Acid, 8 *grammes;* Prepared Lard, 90 *grammes.* Triturate the Atropine with the Oleic Acid, and gently warm the mixture until dissolved; add the Prepared Lard; mix. This Ointment contains 2 per cent. of Atropine. In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

For the uses of this ointment, see under *Belladonna* and *Atropina.* Caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces, and that it be not applied too freely to sound skin.

UNGUENTUM BELLADONNÆ.
U. S., Br.

BELLADONNA OINTMENT Ung. Bellad.

Pomatum; Pommade Belladonée, *Fr.;* Belladonnasalbe, Tollkirschensalbe, *G.;* Pomada de Belladonna, *Sp.*

"Pilular Extract of Belladonna, 10 Gm.; Diluted Alcohol, 5 cc.; Wool Fat, 30 Gm.; Yellow Wax, 5 Gm.; Petrolatum, 50 Gm.; to make about 100 Gm. Triturate the extract with the diluted alcohol until a smooth mixture is obtained, add the wax, wool fat, and petrolatum, which have been melted together on a water bath, and mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 80 *millilitres;* Benzoated Lard, 60 *grammes;* Wool Fat, 20 *grammes.* Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced to twenty grammes; mix with the Benzoated Lard and Wool Fat. This Ointment contains 0.6 per cent. of the alkaloids of Belladonna Root. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoinated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This is a convenient form for the external application of extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence, and be free from lumps; the purpose of the diluted alcohol is to assure the even distribution of the belladonna.

The most important use of this ointment is as a local application in *hemorrhoids.*

UNGUENTUM CANTHARIDINI. Br.

CANTHARIDIN OINTMENT

Unguentum Irritans, Unguentum ad Fonticulos; Onguent de Cantharides, *Fr.;* Spanischfliegensalbe, *G.*

"Cantharidin, 0.1 *gramme;* Chloroform, 10.0 *millilitres;* Benzoated Lard, 290.0 *grammes.* Dissolve the Cantharidin in the Chloroform; add the solution to the Benzoated Lard, previously melted; stir until cold. This Ointment contains 0.033 per cent. of Cantharidin, which is approximately two-thirds of the proportion of Cantharidin contained in the Unguentum Cantharidis of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment is intended as a dressing for blisters, not to produce vesication. The U. S. Committee of Revision wisely deleted this preparation many years ago, as it was frequently prescribed under the impression that it was equal in strength to the cerate, in fact, identical with it, and disappointment resulted. Such a preparation should be left to extemporaneous prescription. *Dupuytren's ointment,* employed as a local application to *prevent the loss of hair,* was made by macerating a drachm of Spanish flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard.

UNGUENTUM CAPSICI. Br.

CAPSICUM OINTMENT

Pommade de Piment das Jardins, *Fr.;* Spanisch-Pfeffersalbe, *G.*

"Capsicum Fruit, bruised, 25 *grammes;* Hard Paraffin, 10 *grammes;* Soft Paraffin, 75 *grammes;* Prepared Lard, 10 *grammes.* Digest on a water-bath for one hour, stirring occasionally; strain; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

This is an active counter-irritant which may be used in the place of liquid liniments in *sprains, bruises, rheumatism,* and other inflammations.

UNGUENTUM CETACEI. Br.

SPERMACETI OINTMENT

Pommade de baleine, *Fr.;* Walrathsalbe, *G.*

"Spermaceti, 20 *grammes;* White Beeswax, 8 *grammes;* Liquid Paraffin, 72 *grammes.* Melt together, and stir until cold." *Br.*

This ointment is employed as a mild dressing for *blisters, wounds,* and *excoriated surfaces,* or as the basis for carrying more active ingredients. It should be made in small quantities at a time, as it is apt to become rancid when long kept.

UNGUENTUM CHAULMOOGRÆ. Br.

CHAULMOOGRA OINTMENT

"Chaulmoogra Oil, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins together; add the Chaulmoogra Oil; stir until cold." *Br.*

This is intended for its local effects; it is not suitable for obtaining the systemic actions of chaulmoogra oil. (See *Oleum Chaulmoogra.*)

UNGUENTUM CHRYSAROBINI. U. S., Br.

CHRYSAROBIN OINTMENT Ung. Chrysarobin.

Pommade de Chrysarobine, *Fr.;* Chrysarobinsalbe, *G.*

"Chrysarobin, 6 Gm.; Hydrous Wool Fat, 94 Gm.; to make about 100 Gm. Triturate the chrysarobin with the hydrous wool fat, previously melted, heat the mixture on a water bath for twenty minutes, with occasional stirring, strain, and stir until the Ointment congeals." *U. S.*

"Chrysarobin, in powder, 4 *grammes;* Soft Paraffin, 96 *grammes.* Triturate the Chrysarobin with a portion of the Soft Paraffin until smooth; gradually add the remainder, mixing thoroughly by trituration." *Br.*

The U. S. ointment is now considerably stronger than the British ointment. The base has been changed in the U. S. X from lard to wool-fat.

It is a valuable agent in *psoriasis, ringworm,* and other *diseases of the skin,* but has the great drawback of leaving a permanent stain upon the linen. It is more easily made by dissolving the chrysarobin in a little hot benzene, mixing this rapidly with a portion of the melted wool-fat (or petrolatum), and subsequently stirring before adding the rest of the base.

UNGUENTUM COCAINÆ. Br.

COCAINE OINTMENT

Pommade d'Oléate de Cocaine, *Fr.;* Cocainoleatsalbe, *G.*

"Cocaine, 4 *grammes;* Oleic Acid, 16 *grammes;* Prepared Lard, 80 *grammes.* Triturate the Cocaine with the Oleic Acid, and gently warm the mixture until the alkaloid is dissolved; add the Prepared Lard; mix. This Ointment contains 4 per cent. of Cocaine. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

UNGUENTUM CREOSOTI. Br.

CREOSOTE OINTMENT

Pommade Créosotée, *Fr.;* Kreosotsalbe, *G.*

"Creosote, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins together; add the Creosote; stir until cold." *Br.*

The British ointment is more than twice as strong as that official in the U. S. P., 1870, which was made by mixing half a fluidrachm of creosote with a troyounce of lard. For the use of this ointment, see *Creosotum.* It may sometimes be advantageously diluted with lard when found to irritate.

UNGUENTUM EUCALYPTI. Br.

EUCALYPTUS OINTMENT

Pommade d'Eucalypte, *Fr.;* Eukalyptussalbe, *G.*

"Oil of Eucalyptus, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins together; add the Oil of Eucalyptus; stir until cold." *Br.*

This ointment is used as a stimulant to indolent *ulcers* and in *skin diseases.*

UNGUENTUM GALLÆ. U. S., Br.

NUTGALL OINTMENT Ung. Gall.

Gall Ointment; Ointment of Galls; Pommade de Noix de Galle, *Fr.;* Galläpfelsalbe, *G.*

"Nutgall, in very fine powder, 20 Gm.; Ointment, 80 Gm.; to make about 100 Gm. Rub the nutgall with the ointment, gradually added, until they are thoroughly mixed. Avoid the use of iron utensils." *U. S.*

"Galls, in powder, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Galls with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Care should be taken to have the nutgall in very fine powder and thoroughly sifted. This ointment is used chiefly in *piles* and *prolapsus ani,* and in *flabby* or *indolent ulcers.*

Off. Prep.—Unguentum Gallæ cum Opio, *Br.*

UNGUENTUM GALLÆ CUM OPIO. Br.

GALL AND OPIUM OINTMENT

"Gall Ointment, 92.5 *grammes;* Opium, in powder, 7.5 *grammes.* Triturate the Opium with a portion of the Gall Ointment until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment contains 7.5 per cent. of Opium." *Br.*

This combination of galls and opium is sometimes employed for *hemorrhoids* but is not a very happy combination. From two to four per cent. of camphor is sometimes added.

UNGUENTUM HAMAMELIDIS. Br.

HAMAMELIS OINTMENT

Pommade de Hamamélis, *Fr.;* Hamamelissalbe, *G.*

"Liquid Extract of Hamamelis, 10 *millilitres;* Wool Fat, 60 *grammes;* Soft Paraffin, 30 *grammes.* Mix by trituration in a warm mortar." *Br.*

This was one of the "Additions" to the British Pharmacopœia, 1885, and afterwards introduced into the Br. Pharm., 1898, 1914. It is, in our opinion, of doubtful utility, but may be applied to *sprains.*

UNGUENTUM HYDRARGYRI AMMONIATI. U. S., Br.

OINTMENT OF AMMONIATED MERCURY Ung. Hydrarg. Ammon. [White Precipitate Ointment]

Unguentum Præcipitati Albi; Ointment of White Precipitate; Pommade de Chloramidure de Mercure, *Fr.;* Unguentum Hydrargyri Album, *P. G.;* Weisse Quecksilbersalbe, *G.*

"Ammoniated Mercury, in very fine powder, 10 Gm.; Liquid Petrolatum, 10 Gm.; Hydrous Wool Fat, 40 Gm.; White Petrolatum, 40 Gm.; to make about 100 Gm. Triturate the ammoniated mercury with the liquid petrolatum until the mixture is smooth, add the white petrolatum, previously melted, mix thoroughly with the hydrous wool fat, and stir the mixture until it congeals." *U. S.*

"Ammoniated Mercury, in powder, 5 *grammes;* Benzoated Lard, 95 *grammes.* Triturate the Ammoniated Mercury with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment is of approximately one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The Br. Pharm., 1914, reduced the strength of this ointment and it is now one-half the strength of the U. S. preparation.

It is used chiefly as a stimulant and parasiticide in cutaneous eruptions, such as *scabies, ringworm, chronic eczema,* and *porrigo.*

UNGUENTUM HYDRARGYRI COMPOSITUM. Br.

COMPOUND MERCURY OINTMENT

"Mercury Ointment, 40 *grammes;* Yellow Beeswax, 24 *grammes;* Olive Oil, 24 *grammes;* Camphor, in flowers, 12 *grammes.* Mix the Yellow Beeswax, Olive Oil, and Mercury Ointment with the aid of heat; add the Camphor; triturate until cold. This Ointment is of approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta,* and *Oleum Olivæ*)." *Br.*

The addition of camphor to mercurial ointment has been thought to soften it and promote absorption of the mercury, but that it has such an effect is very doubtful.

UNGUENTUM HYDRARGYRI FORTIUS. U. S.

STRONGER MERCURIAL OINTMENT Ung. Hydrarg. Fort. [Unguentum Hydrargyri U. S. P. IX]

"Stronger Mercurial Ointment contains not less than 49 per cent. and not more than 51 per cent. of Hg." *U. S.*

Unguentum Neapolitanum; Pomatum Hydrargyricum Gallicum, *Fr. Cod.;* Pommade Mercuriel à parties egales, Onguent Napolitain, *Fr.;* Pomada Mercurial Simple, *Sp.*

"Mercury, 500 Gm.; Oleate of Mercury, 20 Gm.; Prepared Suet, 230 Gm.; Benzoinated Lard, 250 Gm.; to make about 1000 Gm. Triturate the oleate of mercury in a warm mortar, with the mercury added gradually, and when the globules are completely divided and distributed, set it aside for about fifteen minutes. Melt the lard and suet, allow the mixture to partially cool, add about 25 Gm. of it to the mercurial mixture, and continue the trituration until globules of mercury are no longer visible under a lens magnifying ten diameters. Then add the remainder of the lard and suet, and mix thoroughly." *U. S.*

As the name "Unguentum Hydrargyri" is applied all over Europe to an ointment containing only 30 per cent. of mercury the revisers of the U. S. X felt that the name of this ointment, containing 50 per cent. of the metal, should be changed in order to avoid conflict with the Protocol Internationale; at the same time in order to avoid confusion in this country it was felt necessary to add also a limiting adjective to the ointment which corresponds to the internationally accepted strength (see *Unguentum Hydrargyri Mite*). The formula of this is practically unchanged from that of the U. S. IX.

The U. S. official formula is particularly adapted to the extemporaneous preparation of this ointment, it having been shown that the extinguishment of the mercury is facilitated by the use of oleate of mercury, while its presence probably adds to the efficiency of the ointment. Oleic acid was suggested by Leo Eliel (see *Indiana Pharmacist,* 1888) in the proportion of 1 per cent. for the extinction of the mercury. The addition of 4 per cent. of compound tincture of benzoin aids in the preservation of the ointment. The trituration should not be accompanied with pressure, a light, rapid motion of the pestle being most effective. In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is usually performed upon the large scale in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished when a portion of the mass, rubbed upon paper, exhibits no metallic globules under a magnifying glass of ten diameters. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. (For the details of many of these older processes see *U. S. D.,* 19th ed., p. 1310.)

E. R. Squibb prepared this ointment by succussion in an apparatus which agitates the mixture of fats and mercury until the metal is extinguished. When prepared with lard alone, the ointment is liable, in hot weather, to become so soft as to allow the metal to separate. Hence the official use of suet, and even a larger proportion might be employed, during the summer season. The ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 37.7° C., are triturated with the metal by means of two iron balls which are driven rapidly around in a circular trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours. For an account of many expedients that have been proposed to facilitate the extinguishment of the metal, see a paper by Dieterich. (*A. J. P.,* 1880.)

Mercurial ointment has when freshly prepared a bluish color, which becomes darker with age. It was at one time believed to contain the mercury in the state of mercurous oxide, but it is now generally admitted that by far the greater part of it exists in a state of minute division and not of chemical combination. It has been shown, however, that the metal does become slightly oxidized, and the change of color which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. The same change takes place if the ointment is kept for a long time in too warm a place. Christison states that he has examined various samples of the ointment, and never failed to detect mercurial oxides, and he has inferred from his observations that the oxide amounts to rather more than 1 per cent. But the proportion is variable, according to the age and mode of preparation of the ointment.

"**Assay.**—Mix about 1 Gm. of Stronger Mercurial Ointment, accurately weighed, in a suitable flask with 20 cc. of water and 20 cc. of nitric acid, and warm the mixture gently until red fumes cease to be evolved and the solution is colorless. Cool, add 100 cc. of distilled water and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate until a permanent reddish color is produced. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg." *U. S.*

Uses.—Mercurial ointment is intended for the introduction of mercury into the general system, especially for the treatment of *syphilis.* There has been some question as to the method of the absorption of mercury after inunction; there can be no question of the fact of absorption. It has been suggested that what occurs is really a volatilization of mercury and inhalation of it. Schamberg from experiments on rabbits (*J. A. M. A.,* 1918, lxx, 142) came to the conclusion that while there might be some volatilization, the bulk of the mercury that entered the system did so through the skin. The matter appears to have been definitely settled by the observations of Cole, Gericke and Sollmann (*J. A. M. A.,* 1921, lxxvii, p. 2002) who perfected a method of inunction in which the ointment was rubbed into the skin for thirty minutes and at the end of this period the skin was cleansed with benzin which would remove any mercurial ointment that might remain on the outside. They produced salivation in three-fourths of the cases in which this method was employed. Attention may be called to the observation of Cole and Litman (*J. A. M. A.,* Nov. 8, 1919) that a calomel ointment is of no therapeutic value in syphilis probably because of its slight absorption through the skin. It has also been employed as a resolvent in local affections, as in the case of *venereal buboes,* and of *chronic glandular swellings,* with the thought that it may operate directly by being applied in the course of the absorbents passing through the enlarged glands.

It is best absorbed if applied over those areas of the body where the skin is thin, as the bend of the elbows or knees, or the groins. The friction should on each occasion be continued till the ointment is not visible on the skin. When frequently rubbed upon the same part, it is prone to produce a disagreeable eruption, which interferes with its continued application, and it is therefore advisable to apply it to different parts if used on successive days. Mercurial ointment has been employed, with some success, to prevent the maturation of the *small pox pustule,* and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in *erysipelas* and in *chilblains.*

Dose, one-half to one drachm (2–4 Gm.). It is usually dispensed in dosage packets, each wrapped separately in waxed paper.

Off. Prep.—Unguentum Hydrargyri Dilutum, *U. S.*

UNGUENTUM HYDRARGYRI IODIDI RUBRI. Br.

MERCURIC IODIDE OINTMENT

Ointment of Mercuric Iodide; Ointment of Red Iodide of Mercury; Pommade d'Iodure Mercurique, *Fr.;* Jodquecksilbersalbe, *G.*

"Red Mercuric Iodide, in powder, 4 *grammes;* Benzoated Lard, 96 *grammes.* Triturate the Red Mercuric Iodide with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment is employed as a dressing to indolent *scrofulous* and *syphilitic ulcers.*

UNGUENTUM HYDRARGYRI MITE. U. S.

MILD MERCURIAL OINTMENT Ung. Hydrarg. Mit. [Unguentum Hydrargyri Dilutum U. S. P. IX, Diluted Mercurial Ointment, Blue Ointment, Hydrargyri unguentum P. I.]

"Mercurial Ointment contains not less than 29 per cent. and not more than 31 per cent. of Hg." *U. S.*

Unguentum Hydrargyri, *Br.;* Mercury Ointment; Unguentum Mercuriale; Blue Ointment; Unguentum Coeruleum; Pomatum Hydrargyricum Dilutum, *Fr. Cod.;* Pommade Mercurielle Faible, *Fr.;* Unguentum Hydrargyri Cinereum, *P. G.;* Grauesalbe, Quecksilbersalbe, *G.;* Pomada Mercurial, *Sp.*

"Stronger Mercurial Ointment, 600 Gm.; Petrolatum, 200 Gm.; Ointment, 200 Gm.; to make about 1000 Gm. Mix the ingredients thoroughly.

"**Assay.**—Proceed as directed under *Unguentum Hydrargyri Fortius.*" *U. S.*

"Mercury, 30 *grammes;* Benzoated Lard, 65 *grammes;* Prepared Suet, 5 *grammes.* Triturate until metallic globules cease to be visible. This Ointment is of approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898; it is of the same strength as the Unguentum Hydrargyri of the International Agreement. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment was introduced into the U. S. P. (8th Rev.) to correspond to the recommendations of the International Conference; it should be kept in a cool place in the summer, as otherwise the mercury may separate on account of the softening of the fatty vehicle.

A substitute for *blue ointment* has been proposed by a French pharmacist, which is made as follows: 23.5 Gm. of mercuric chloride is triturated with 8.1 Gm. of sodium sulphocyanate and enough lanolin and petrolatum to make 100 Gm. The sulphocyanate reduces the mercuric chloride with the production of metallic mercury in a finely divided state and the resulting preparation is said to be very similar in its effect to blue ointment and to be much more easily prepared. (*Bull. Pharm.,* 1914, 306.)

The U. S. mild mercurial ointment is used only for the destruction of parasites and vermin on the skin. It is not suited for producing the systemic action of mercury as the petrolatum base does not so readily penetrate the skin. For anti-syphilitic inunctions the strong mercurial ointment should be employed. The British preparation may be used for either purpose.

UNGUENTUM HYDRARGYRI NITRATIS. Br.

MERCURIC NITRATE OINTMENT

Ointment of Nitrate of Mercury; Unguentum Citrinum; Citrine Ointment; Unguentum Hydrargyri Citrinum; Pommade Citrine, *Fr. Cod.;* Onguent Citrin, *Fr.;* Quecksilbernitratsalbe, Gelbe Quecksilbersalbe, *G.*

"Mercury, 10 *grammes;* Nitric Acid, 30 *millilitres;* Prepared Lard, 40 *grammes;* Olive Oil, 70 *grammes.* Dissolve the Mercury in the Nitric Acid without the aid of heat, shaking gently from time to time. Heat the Prepared Lard and Olive Oil together on a sand-bath, so that the mixture when transferred to a heated earthen jar, capable of holding ten times the quantity, is at a temperature of about 150° C. Add the cold mercurial solution very gradually, stirring constantly with a glass or wooden spatula to promote the disengagement of fumes. Keep the mixture at a temperature of not less than 90° C. until frothing ceases, then stir until cold. (See Appendix XII, Part III, *Unguenta,* and *Oleum Olivæ.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The chemical changes which take place in the preparation of this ointment are complex.

They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. In the British process the mercury, in the first step of the process, is converted into a mixture of mercuric and mercurous nitrate by the addition of nitric acid in excess, with the loss of some of the free nitric acid through deoxidation. When the acid mercurial solution is added to the fatty matter, a reaction takes place, which results in the fat being oxidized at the expense of the free nitric acid, nitrogen dioxide and nitrogen tetroxide being at the same time liberated, and the olein of the fat is converted into elaidin, which change is recognized by the beautiful orange color of the fat. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty-greenish and mottled color, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and many different modifications of the process were proposed in order to obviate them. The present official process was based on Rother's formula (*A. J. P.*, xlii, 420). The value of this process lies principally in the fact that the olein of the oil is first converted into elaidin by the addition of nitric acid alone and the application of heat; when the reaction has ceased and the basis of citrine ointment, as it might be called, is prepared, and nearly cold, the mercurial solution is added. In this way decomposition of the mercuric nitrate is avoided, as it is not subjected to heat, and the result is an ointment which will retain its color and consistence a long time. Care must be taken that the heat applied be not too great. Gas is extricated at 82.2° C., and at 100° C. escapes so abundantly that the mixture boils over unless the vessel is very large. (Alsop.) Besides, if the heat be too great, a portion of the mercury will be reduced, and the color of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel, and a glass rod or a wooden spatula should be employed for stirring the mixture. Under no circumstances should an iron or steel spatula or stirrer be used in its preparation, because of the contamination and discoloration due to the action of the acid upon the iron.

Uses.—This ointment is much and very advantageously employed, as a stimulant and alterative application, in *porrigo* or *tinea capitis, impetigo larvalis, psoriasis, sycosis, pityriasis,* certain forms of *chronic eczema,* and various other eruptive affections. It is an active parasiticide and antiseptic, highly stimulating and generally should be diluted with lard, unless in very sluggish cases. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. An ointment prepared with lard and nitric acid, called *Alyon's ointment,* after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias was of this character.

Off. Prep.—Unguentum Hydrargyri Nitratis Dilutum, *Br.*

UNGUENTUM HYDRARGYRI NITRATIS DILUTUM. Br.

DILUTED MERCURIC NITRATE OINTMENT [Diluted Ointment of Nitrate of Mercury]

"Mercuric Nitrate Ointment, 20 *grammes;* Soft Paraffin, yellow, 80 *grammes.* Mix by trituration." *Br.*

UNGUENTUM HYDRARGYRI OLEATI. Br.

MERCURIC OLEATE OINTMENT

Pommade d'Oléate Mercurique, *Fr.;* Quecksilberoleatesalbe, *G.*

"Oleated Mercury, 25 *grammes;* Benzoated Lard, 75 *grammes.* Mix by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

UNGUENTUM HYDRARGYRI OXIDI FLAVI. U. S., Br.

OINTMENT OF YELLOW MERCURIC OXIDE
Ung. Hydrarg. Oxid. Flav.

"NOTE.—The strength of this Ointment has been reduced from 10 per cent. of Yellow Mercuric Oxide to 1 per cent." *U. S.*

Yellow Mercuric Oxide Ointment; Pomatum Hydrargyri Oxydati Flavi, *Fr. Cod.;* Pommade d'oxyde de mercure jaune, *Fr.;* Gelbe Quecksilberoxydsalbe, *G.;* Pomadada de Oxido Mercurico Amarillo, *Sp.*

"Yellow Mercuric Oxide, in very fine powder, 1 Gm.; Liquid Petrolatum, 1 Gm.; Hydrous Wool Fat, 10 Gm.; Petrolatum, 88 Gm.; to make about 100 Gm. Triturate the yellow mercuric oxide with the liquid petrolatum until the mixture is smooth, add the hydrous wool fat in divided portions, and incorporate the mixture thoroughly with the petrolatum. All contact with iron utensils or containers must be avoided." *U. S.*

"Yellow Mercuric Oxide, in powder, 2 *grammes;* Soft Paraffin, yellow, 98 *grammes.*

Triturate the Yellow Mercuric Oxide with a portion of the Soft Paraffin until smooth; gradually add the remainder, mixing thoroughly by trituration." *Br.*

Sjöström (*Ph. Ztg.,* 1915, 554) gives the following method for the assay of this ointment. 1.0 Gm. of the ointment is dissolved in 25 cc. of ether. The solution, in a glass-stoppered bottle, is mixed with 25 cc. potassium iodide solution (1+9), 20 cc. N/10 hydrochloric acid, and 1 cc. phenolphthalein solution, then titrated, shaking vigorously, with N/10 potassium hydroxide. 1 cc. N/10 hydrochloric acid = 0.01083 Gm. mercuric oxide, phenolphthalein as indicator. The method depends on the property of potassium iodide combining with finely divided mercuric oxide immediately and quantitatively according to the equation

$$3KI + HgO + H_2O = KHgI_3 + 2KOH.$$

The potassium hydroxide formed may be determined in the usual manner. The method is useful for ointments of any percentage of mercuric oxide and gives very exact results.

Uses.—This is the least irritant of the official ointments of the mercurial salts. It possesses the disinfectant and local stimulating properties of the mercury preparations and is used in various skin diseases, especially in *eczema* of the auditory canal or eye-lid, and in *hordeolum.* The U. S. ointment has been greatly reduced in strength and is now only half as strong as the Br. preparation.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. Br.

RED MERCURIC OXIDE OINTMENT
[Red Precipitate Ointment]

Unguentum Præcipitati Rubri; Pommade d'oxyde de Mercure rouge, *Fr. Cod.;* Pommade de Lyon, Pommade de Précipité rouge, Baume ophthalmique rouge, *Fr.;* Unguentum Hydrargyri Rubrum, *P. G.;* Rothe Quecksilbersalbe, *G.;* Pomada de Oxido Mercurico Rojo, *Sp.*

"Red Mercuric Oxide, in powder, 10 *grammes;* Paraffin Ointment, yellow, 90 *grammes.* Melt the Paraffin Ointment; sift in the Red Mercuric Oxide; stir until cold." *Br.*

Red Precipitate Ointment was deleted from the U. S. P. IX but has been added to the N. F. (see Part III). It has been largely replaced in medical practice by Yellow Mercuric Oxide Ointment, which is a more desirable preparation.

The red mercuric oxide here referred to is that prepared from the nitrate and usually called *red precipitate.* It is important that the oxide should be thoroughly pulverized before being mixed with the lard, as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used. When great care is taken to have the red oxide very finely pulverized, the color is more yellowish than is usual. This ointment loses its fine red color when kept long, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it in small quantities at a time. The U. S. P. (8th Rev.) process was an improvement over the process of the U. S. P. 1890, particularly in the choice of the vehicle.

Ointment of red mercuric oxide is more highly stimulating than that of the yellow oxide and is used for different purposes. It is employed in *indolent and foul ulcers,* and *various skin diseases.* It may be diluted with lard if found too stimulating.

UNGUENTUM HYDRARGYRI SUBCHLORIDI. Br.

MERCUROUS CHLORIDE OINTMENT
[Calomel Ointment]

Unguentum Calomelanos, *Br.* 1864; Ointment of Subchloride of Mercury; Ointment of Calomel; Pomatum Hydrargyri Chlorati, *Fr. Cod.;* Pommade de Calomél, *Fr.;* Quecksilberchlorürsalbe, *G.;* Pomada de Cloruro Mercurioso Precipitado, *Sp.*

"Mercurous Chloride, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Mercurous Chloride with a portion of the Benzoated Lard, until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment is of twice the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Uses.—While ointments of calomel are often of much value in the same class of cases for which the yellow oxide is employed, this ointment is far too strong. We believe ointments of this character might well be left to extemporaneous prescription.

UNGUENTUM IODI. U. S., Br.

IODINE OINTMENT Ung. Iodi

Unguentum Iodinii, *U. S.* 1870; Pommade d'iodure de potassium iodée, *Fr. Cod.;* Pommade d'Iode, *Fr.;* Jodsalbe, *G.;* Pomada de Yoduro Potasico Yodada, *Sp.*

"Iodine, 4 Gm.; Potassium Iodide, 4 Gm.; Glycerin, 12 Gm.; Wool Fat, 80 Gm.; to make about 100 Gm. Triturate the iodine and potassium iodide, preferably in a glass mortar with the glycerin until dissolved, gradually incorporate the wool fat, and mix thoroughly. All contact with metallic utensils or containers must be avoided." *U. S.*

"Iodine, 4 *grammes;* Potassium Iodide, 4 *grammes;* Glycerin, 12 *grammes;* Prepared Lard, 80 *grammes.* Triturate the Iodine, Potassium Iodide, and Glycerin in a glass or porcelain mortar; add the Prepared Lard; mix thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

It has been stated that if there were no potassium iodide and glycerin present in iodine ointment, that 95 per cent. of the iodine would be "absorbed" by the lard in a short time. Some absorption and diminution of strength in iodine content does take place even in the present formula. It would seem, therefore, that the Br. preparation is distinctly superior to that of the U. S.

Miles Shimer (*Proc. P. P. A.*, 1915, p. 304) suggests that by keeping the iodine, potassium iodide and glycerin already made up as a stock solution, the dispensing of U. S. P. iodine ointment is much more expeditiously accomplished.

The change of base in the U. S. X formula seems to us peculiarly unfortunate. Hirschfeld and Pollio (*Arch. f. Derm. u. Syph.*, 1904, lxxii, p. 163) found that iodides were readily absorbed from ointments made with either petrolatum or lard, although scarcely at all from those made from wool-fat. Guttmann (*Z. K. M.*, 1887, xii, p. 276) found that the absorption from lard was superior to that from wool-fat.

Uses.—Ointment of Iodine is useful both for the local counter-irritant effect of the element and as a means of obtaining the constitutional action of the iodides. It is commonly believed that this ointment exercises a local resolvent action and it is therefore employed in various forms of *arthritis, goiter, scrofulous swellings of the glands,* and other *chronic tumefactions.*

When rubbed upon the skin it imparts to it an orange color, which, however, slowly disappears with the absorption of the iodine. When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. It has also been recommended in *chilblains.* The ointment should be prepared only when wanted for use, for it undergoes change if kept, losing its deep orange-brown color and becoming pale upon its surface, due to the combination of part of the iodine with the fat.

UNGUENTUM IODOFORMI. U. S., Br.

IODOFORM OINTMENT Ung. Iodof.

Pommade d'Iodoforme, *Fr.;* Jodoformsalbe, *G.;* Pomada de Yodoformo, *Sp.*

"Iodoform, 10 Gm.; Wool Fat, 20 Gm.; Petrolatum, 70 Gm.; to make about 100 Gm. Triturate the Iodoform with the previously melted petrolatum until dissolved, incorporate the wool fat, and mix thoroughly." *U. S.*

"Iodoform, in powder, 10 *grammes;* Prepared Lard, 90 *grammes.* Triturate the Iodoform with a portion of the Prepared Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

It is important to have the iodoform in very fine powder, as officially directed, and, owing to the powerful odor of iodoform, it is usual to add oil of bitter almond or one of the other volatile oils, balsam of Peru, or a similar substance, to render the odor less unpleasant.

UNGUENTUM LANÆ COMPOSITUM. Br.

COMPOUND WOOL-FAT OINTMENT [Emollient Ointment]

"Prepared Lard, 40 *grammes;* Wool Fat, 40 *grammes;* Paraffin Ointment, 20 *grammes.* Melt together; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The addition of the paraffin ointment to wool-fat overcomes the stickiness which is so frequently an obstacle to the employment of that emollient.

UNGUENTUM MYROBALANI. Br.

MYROBALAN OINTMENT

"Myrobalans, in powder, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Myrobalans with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This is used as a local astringent.

Off. Prep.—Unguentum Myrobalani cum Opio, *Br.*

UNGUENTUM MYROBALANI CUM OPIO. Br.

MYROBALAN AND OPIUM OINTMENT

"Myrobalan Ointment, 92.5 *grammes;* Opium, in powder, 7.5 *grammes.* Triturate the Opium with a portion of the Myrobalan Ointment until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment contains 7.5 per cent. of Opium." *Br.*

UNGUENTUM PARAFFINI. Br.

PARAFFIN OINTMENT

Pommade de Paraffin, *Fr.;* Paraffinsalbe, *G.*

"Hard Paraffin, 27 *grammes;* Soft Paraffin, 70 *grammes;* White Beeswax, 3 *grammes.* Melt together; stir until cold. When Paraffin Ointment is used as the basis of white ointments it should be prepared with the white variety of Soft Paraffin; and when used for colored ointments it should be prepared with the yellow variety of Soft Paraffin. (See Appendix XII, Part III, *Unguenta.*)" *Br.*

This is recognized by the Br. for use as a vehicle in the exhibition of various medicaments.

UNGUENTUM PHENOLIS. U. S. (Br.)

OINTMENT OF PHENOL Ung. Phenol. [Ointment of Carbolic Acid]

Unguentum Acidi Carbolici, *Br.;* Carbolized Petrolatum; Pomatum Phenoli, *Fr. Cod.;* Pommade de Phénol, Vaseline Phéniquée, *Fr.;* Karbolsalbe, Phenolsalbe, *G.;* Pomada de Acido Ferrico, *Sp.*

"Phenol, 2 Gm.; Yellow Wax, 5 Gm.; Petrolatum, 93 Gm.; to make about 100 Gm.

Melt the yellow wax and phenol on a water bath, add the petrolatum, and stir the mixture until it congeals." *U. S.*

"Phenol, 3 *grammes;* Paraffin Ointment, white, 97 *grammes.* Melt the Paraffin Ointment; in it dissolve the Phenol; stir until cold." *Br.*

The base of this ointment has been changed in the U. S. X to one composed largely of petrolatum. This is an improvement as the researches of McMaster have shown that a petrolatum solution of phenol is germicidal, while one in true fats is not. At the same time the proportion of phenol has been slightly reduced which is also an advantage; the Br. ointment is too strong for most purposes.

It is a useful antiseptic for small wounds and sores of various types.

UNGUENTUM PICIS PINI. U. S. (Br.)

TAR OINTMENT Ung. Pic. Pin. [Unguentum Picis Liquidæ U. S. P. IX]

Unguentum Picis Liquidæ, *Br.;* Pommade de Goudron, *Fr. Cod.;* Theersalbe, *G.;* Pomada de Brea, *Sp.*

"Pine Tar, 50 Gm.; Yellow Wax, 15 Gm.; Petrolatum, 35 Gm.; to make about 100 Gm. Melt the yellow wax, add the petrolatum, and to the melted mixture add the pine tar, previously warmed, and incorporate thoroughly. Strain the mixture through muslin, and stir until it congeals." *U. S.*

"Tar, 70 *grammes;* Prepared Lard, 5 *grammes;* Yellow Beeswax, 25 *grammes.* Melt together; stir until cold. (See Appendix XII, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The U. S. X. has modified the formula of this ointment by the substitution of petrolatum for the lard formerly official. It is considerably lower in content of tar than the British preparation.

This ointment is highly useful as a stimulant application in various *scaly* and *scabby eruptions,* particularly in *psoriasis* and *chronic eczema* and also for its anti-parasitic effect in *tinea capitis* or similar *skin diseases.* In the last-mentioned affection it should be applied night and morning, and in bad cases the patient should constantly wear a cap thickly coated internally with the ointment. In some cases it requires dilution with an equal quantity of lard to avoid irritation.

UNGUENTUM PLUMBI IODIDI. Br.

LEAD IODIDE OINTMENT

Lead Iodide Ointment; Pommade d'Iodure de Plomb, *Fr. Cod.;* Jodbleisalbe, *G.;* Pomado de Yoduro Plumbico, *Sp.*

"Lead Iodide, in powder, 10 *grammes;* Benzoated Lard, 90 *grammes.* Triturate the Lead Iodide with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

For the uses of this ointment, see *Plumbi Iodidum.* It is also official in the N. F. (see Part III).

UNGUENTUM PLUMBI OLEATIS. U. S.

OINTMENT OF LEAD OLEATE Ung. Plumb. Ol. [Unguentum Diachylon U. S. P. IX]

Unguentum Plumbi Hebræ; Hebra's Lead Ointment; Diachylon Ointment; Onguent Diachylon, Pomade de Diachylon, *Fr.;* Unguentum diachylon, *P. G.;* Bleipflastersalbe, Diachylonsalbe, *G.*

"Lead Oleate Plaster, 50 Gm.; Oil of Lavender, 1 Gm.; White Petrolatum, 49 Gm.; to make about 100 Gm. Melt together the lead oleate plaster and the white petrolatum by applying a gentle heat, strain the mixture, allow it to cool but not congeal, add the oil of lavender, and stir the Ointment until it is cold." *U. S.*

This ointment has been largely used by dermatologists in *eczema* and other *skin diseases.* It is frequently called *"Unguentum Diachylon Hebræ,"* on account of its extensive use by Hebra, of Vienna. Vulpius states that the ointment used at Hebra's clinic, made according to the following formula, is very superior and will keep for weeks: Twenty parts of litharge are heated with sufficient water and eighty parts of olive oil until the reaction is completed, when one part of oil of lavender is added to the strained and cooling mass. Our experience with the ointment made by this formula is that the tendency to rancidity constitutes its greatest objection, and in warm weather it is impossible to keep it longer than a few days. If even slightly rancid, it is unfit for use in most cases.

The official ointment is the same as that of the U. S. IX, which has proven fairly stable and has given satisfaction. Other suggested modifications may be found in the *U. S. D.,* 20th ed., p. 1177.

UNGUENTUM PLUMBI SUBACETATIS. Br.

LEAD SUBACETATE OINTMENT

"Strong Solution of Lead Subacetate, 12.5 *grammes;* Wool Fat, 25.0 *grammes;* Hard Paraffin, 12.5 *grammes;* Soft Paraffin, 50.0 *grammes.* Melt together the Wool Fat and the Hard and Soft Paraffins; stir until nearly cold; add the Strong Solution of Lead Subacetate, and continue to stir until cold." *Br.*

The white petrolatum, wool-fat and paraffin now used in this ointment are preferable to the lard and cottonseed oil formerly employed, as they are free from the great objections to the former official cerate, of proneness to rancidity, and discoloration. This cerate received the name by which it is commonly known from Goulard, by whom it was employed and recommended. (See also *Ceratum Plumbi Subacetatis,* N. F., Part III.)

The ointment of subacetate of lead was formerly largely used in *excoriations, burns, scalds,* and *chilblains,* but is infrequently employed at present.

UNGUENTUM POTASSII IODIDI. Br.

POTASSIUM IODIDE OINTMENT

Ointment of Potassium Iodide; Pommade d'Iodure de Potassium, *Fr. Cod.;* Unguentum Kalii jodati, *P. G.;* Jodkaliumsalbe, Kaliumjodidsalbe, *G.*

"Potassium Iodide, 10.0 *grammes;* Potassium Carbonate, 0.6 *gramme;* Distilled Water, 9.4 *grammes;* Benzoated Lard, 80.0 *grammes.* Dissolve the Potassium Iodide and Potassium Carbonate in the Distilled Water; mix the solution, gradually, with the Benzoated Lard, in a slightly warmed mortar. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The former ointments of potassium iodide became discolored by time in consequence of the liberation of iodine. This was due to rancidity in the lard, and the slightest change in the fat would produce some discoloration. It was prevented in the U. S P. 1880 by the sodium thiosulphate, which also produces traces of sodium iodide and sulphur. The addition of potassium carbonate by the present Br. Pharmacopœia is made with the same object.

The *Bulletin de Pharmacie du Nord* recommended a concentrated solution of potassium iodide in glycerin as a basis for this ointment. One gramme of the salt is dissolved in two and a half grammes of hot glycerin, and the solution mixed with the fatty constituent in the proper proportion. The advantages of this method are that the ointment is free from crystals, and the salt more readily absorbed. The glycerin would probably not be objectionable in most cases, and potassium carbonate could be added, if desired. Ointment of potassium iodide is employed for the discussion of *goiters, scrofulous tumors,* and other *indolent swellings,* and is sometimes preferred to the ointment of iodine, as it does not, like that, discolor the skin. It does not, however, possess the antiseptic nor counter-irritant properties of the free iodine.

UNGUENTUM STAPHISAGRIÆ. Br.

STAVESACRE OINTMENT

Onguent de Staphisaigre, *Fr.;* Stephanskörnersalbe, *G.*

"Stavesacre Seeds, 20 *grammes;* Yellow Beeswax, 10 *grammes;* Benzoated Lard, 85 *grammes.* Crush the Stavesacre Seeds; digest the crushed seeds with the Benzoated Lard on a water-bath for two hours; strain and press through calico; melt the Beeswax in the liquid mixture; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment is but half the strength of that official in the British Pharmacopœia 1885; it is said to be non-irritant, and is largely used in Great Britain for destroying *body-lice,* also in *scabies* and *prurigo.*

UNGUENTUM SULPHURIS. U. S., Br.

SULPHUR OINTMENT Ung. Sulphur.

Pomatum Sulfuratum, Unguentum Sulfuratum Simplex; Pommade Soufrée, *Fr. Cod.;* Schwefelsalbe, *G.*

"Sublimed Sulphur, 15 Gm.; Benzoinated Lard, 85 Gm.; to make about 100 Gm. Rub the sublimed sulphur, which must be free from gritty particles, with a small portion of the benzoinated lard until smooth, and incorporate uniformly the remainder of the benzoinated lard with the sulphur mixture." *U. S.*

"Sublimed Sulphur, 10 *grammes;* Benzoated Lard, 90 *grammes.* Triturate the Sublimed Sulphur with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Washed sulphur was substituted in the U. S. P., 1890, for the sublimed sulphur of the former Pharmacopœia; the change was of questionable utility and the U. S. P. has returned to the use of sublimed sulphur. It has been found that the acid products resulting from the slight decomposition in sublimed sulphur have value as parasiticides. The disagreeable odor may be partially concealed by oil of lemon or oil of bergamot.

This ointment affords a ready means of obtaining the local action of sulphur. For discussion of its properties, see *Sulphur.*

UNGUENTUM ZINCI OLEATIS. Br.

ZINC OLEATE OINTMENT

Pommade d'oléate de zinc, *Fr.;* Zinkoleatsalbe, *G.*

"Zinc Sulphate, 30 *grammes;* Hard Soap, in shavings, 90 *grammes;* Distilled Water, boiling, Soft Paraffin, white, of each, *a sufficient quantity.* Dissolve the Zinc Sulphate in sixty millilitres of the Distilled Water. Dissolve the Hard Soap in six hundred millilitres of the Distilled Water. Mix the solutions; heat to boiling; allow the melted zinc oleate so produced to rise to the surface; cool until it solidifies; pour off the aqueous liquid; boil the zinc oleate with successive quantities of Distilled Water until the washings afford not more than a slight *reaction* for sulphates; reduce the cake thus obtained to a coarse powder; dry at a temperature below 60° C., melt on a water-bath with an equal weight of the Soft Paraffin; stir until cold." *Br.*

This ointment was radically changed in the Br. Ph., 1898, revision; instead of using zinc oleate made from oleic acid and zinc oxide, a process is ordered which directs the zinc oleate to be made by double decomposition between zinc sulphate and sodium oleo-stearate (hard soap). The product is a white, fine precipitate; it is, however, not a pure oleate, but a zinc oleo-stearate or oleo-palmitate.

This preparation has therapeutic properties similar to those of the ointment of zinc oxide, but is a little more stimulating. It is especially useful in *chronic eczema* and similar *cutaneous eruptions.*

UNGUENTUM ZINCI OXIDI. U. S. (Br.)

OINTMENT OF ZINC OXIDE Ung. Zinc. Ox. [Zinc Ointment]

Unguentum Zinci, *Br.;* Ointment of Zinc; Unguentum de Nihilo Albo; Pommade d'Oxyde de Zinc, Cérat épulotique, *Fr.;* Unguentum Zinci, *P. G.;* Zinksalbe, *G.;* Pomada de Oxido Zincico, *Sp.*

"Zinc Oxide, in very fine powder, 20 Gm.; Paraffin, 15 Gm.; White Petrolatum, 65 Gm.; to make about 100 Gm. Rub the zinc oxide, which must be free from gritty particles, with about one-fourth of the melted paraffin and white petrolatum in a previously warmed container, and with this incorporate the remainder of the melted mixture. If necessary, strain the Ointment while warm, and stir until it congeals." *U. S.*

"Zinc Oxide, 15 *grammes;* Benzoated Lard, 85 *grammes.* Mix by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The assay of this ointment for its zinc oxide content may be easily accomplished, according to J. L. Mayer (*Proc. N. Y. P. A.*, 1913, p. 226) by igniting a weighed portion of the ointment and weighing the resulting zinc oxide. Care should be taken, after combustion has begun, to withdraw the burner and allow the sample to burn quietly until all inflammable matter is consumed. If the resulting oxide is not white in color it may be moistened with nitric acid and re-ignited. The same procedure will serve for the assay of ointment of zinc stearate.

The British ointment is weaker in the proportion of zinc oxide than that of the U. S. Pharmacopœia, the former containing about 15 per cent., the latter 20 per cent. *Commercial* zinc oxide should not be used, as it is usually gritty, and it is difficult to make a smooth ointment with it. Commercial zinc oxide is sometimes contaminated with lead to an appreciable amount and for that reason alone should not be employed in making this important and widely used ointment; the many expedients that have been suggested by various writers, such as the use of a paint mill or of a flat iron, or trituration with oil or with glycerin, are unnecessary if official zinc oxide is employed and the directions of the Pharmacopœia followed.

The change in the base of this important ointment from lard to petrolatum was made by the U. S. X after consultation, by questionnaire, with the members of the American Dermatological Society. Nevertheless we feel that the new ointment will have somewhat different therapeutic action from that formerly official. With a lard base the fat is largely absorbed and leaves a protective deposit of zinc oxide on the skin; with the new formula the petrolatum being almost non-absorbable the skin remains more greasy. The new preparation has the advantage of not becoming rancid.

To what the peculiar virtues of this ointment are due is not certainly known. The emollient effect of the base and the protective action of the metallic salt are obviously important properties, but the ointment seems to have some other influence on the skin; perhaps the zinc may exert a mild antiseptic or astringent action. However it acts, it is one of the most widely employed unguents in a large variety of diseases and irritations of the skin.

URGINEA. Br.

URGINEA [Indian Squill]

"Urginea consists of the younger bulbs of Urginea indica, *Kunth,* collected soon after the plants have flowered, divested of their dry, outer, membranous coats, cut into slices, and dried. When powdered should be kept quite dry over quicklime." *Br.*

Urginea indica is a plant resembling *Urginea maritima* (see *Scilla*) but produces a smaller tunicated bulb. Urginea indica grows in sandy soil near the sea coast throughout India and also extends to the lower Himalayas. The medicinal properties of the drug are apparently identical with the squill of the Greeks. The outer coats are quite inert and should be removed as indicated in the definition of the Br. Pharm.

"Curved or sickle-shaped strips, separated or connected, several together, to a portion of the shortened axis; usually one to five centimetres long and five to ten millimetres wide; yellowish-white, fleshy, often longitudinally ribbed; tough when slightly moist, but brittle and pulverisable when dry. No odor; taste bitter and acrid." *Br.*

The bulbs of *Urginea indica* are rounded, conical or pear-shaped and about the size of an onion; tunicated, consisting of fleshy coats which enclose each other completely; color whitish; taste bitter and acrid.

Uses.—The bulbs of Indian squill have long been used in India for purposes similar to that for which the official squill is employed in Europe and America, but no sufficient chemical examinations have been made to prove the identity of the Indian and European drugs.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Acetum Urgineæ, *Br.;* Oxymel Urgineæ (from Vinegar), *Br.;* Pilula Ipecacuanhæ cum Urginea, *Br.;* Pilula Urgineæ Composita, *Br.;* Syrupus Urgineæ, *Br.;* Tinctura Urgineæ, *Br.*

UVA URSI. U. S. (Br.)

UVA URSI [Bearberry]

"Uva Ursi is the dried leaf of *Arctostaphylos Uva-ursi* (Linné) Sprengel (Fam. *Ericaceæ*). Uva Ursi contains not more than 5 per cent.

of its stems or other foreign organic matter." *U. S.* "Bearberry Leaves are the dried leaves of Arctostaphylos Uva-ursi, *Spreng.*" *Br.*

Uvæ Ursi Folia, *Br.;* Barren Myrtle, Mountain Box, Rockberry; Kinnikinnic; Busserole, Raisin d'Ours, *Fr.;* Folia Uvae Ursi, *P. G.;* Bärentraubenblätter, *G.;* Uva Ursina, *It.;* Gayuba, *Sp.*

The *uva ursi,* or *bearberry,* is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upward for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, or oblong-spatulate, acute at the base, obtuse at the apex, entire, with a rounded margin, thick coriaceous, smooth, shining, deep green on their upper surface, paler and covered with a network of veins beneath; furnished especially near the margin or near the midrib with minute hairs, which are usually abundant in young leaves, but may be few or absent in old leaves, especially those which have been much handled. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the ovary round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy red berry, with an insipid mealy pulp and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes and high mountains of Europe, Asia, and America. On the American continent it extends from Hudson Bay as far southward as New Jersey and Pennsylvania, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills and elevated sandy plains. The leaves are the only part used in medicine. They should be gathered in autumn, and only the green leaves selected. The present commercial supplies of this drug are partly imported from Spain and partly obtained from plants growing wild in California and the northwestern states.

In Europe the uva ursi is adulterated with the inert leaves of the *Vaccinium Vitis-Idæa* L. (*Cowberry, Mountain Cranberry*); these may be distinguished by being obovate, having revolute margins which are sometimes slightly toothed, and the presence of fine blackish dots or bristly points upon their lower surface. Leaves of the *Chimaphila umbellata* (L.) Nutt., sometimes found among the uva ursi, may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Arctostaphylos glauca Lindl., *manzanita,* is a small tree or shrub indigenous in California, where it generally grows in dry and rocky places on the west of the mountain ranges. The leaves appear to possess properties similar to those of the official species. (See Flint, *A. J. P.,* 1873, p. 187.) The fruit of *A. arguta* Zucco, a Mexican species, is said to be a narcotic poison.

Description and Physical Properties.—"*Unground Uva Ursi.*—Usually unbroken, obovate, oblong or spatulate, from 12 to 30 mm. in length, from 5 to 13 mm. in breadth; apex obtuse or rounded; margin entire, slightly revolute; base cuneate, tapering into a short, stout petiole; upper surface dark green, glabrous and shiny, finely reticulate; under surface yellowish-green and slightly pubescent, especially on the midrib; coriaceous; fracture short; odor slightly aromatic, tea-like; taste astringent and somewhat bitter.

"*Powdered Uva Ursi.*—Olive green; epidermal cells polygonal, those of the lower surface showing broadly elliptical stomata about 0.04 mm. in length, surrounded by 5 to 8 neighboring cells; cells of mesophyll with chloroplastids and frequently irregular masses of a carbohydrate; fragments of fibro-vascular bundles with spiral tracheæ associated with narrow, strongly lignified, sclerenchymatous fibers and frequently also with crystal-fibers showing mono-clinic prisms, from 0.006 to 0.030 mm. in diameter; numerous fragments made up of cells having a yellowish-brown content colored a bluish-black upon the addition of ferric chloride T.S.

"Place 0.1 Gm. of powdered Uva Ursi on a watch crystal, cover with another watch crystal, and gently heat the powder: a crystalline sublimate of hydroquinonone is formed, consisting of long rods and feather-like aggregates which polarize light with a brilliant play of colors. Macerate 1 Gm. of powdered Uva Ursi with 10 cc. of boiling water, shake the mixture occasionally until cold, and filter: the filtrate yields a grayish-purple precipitate upon the addition of a few drops of ferrous sulphate T.S." *U. S.*

"Obovate or spatulate, about two centimetres long, yellowish-green, coriaceous, entire, shortly petiolate. Upper surface glabrous, shining, reticulate; veinlets depressed. Slight odor; taste very astringent." *Br.*

The commercial drug frequently consists of the entire plants and therefore contains a large quantity of stems. The latter should not be present, according to the official definition, in greater amount than five per cent. Farwell states that the leaves are sometimes very dark or blackish-green, which is probably due to carelessness in drying. (*M. R.,* xvii, p. 35.) Holm has contributed an interesting article on the morphology of the plant. (*M. R.,* xx, p. 95.)

Uva ursi leaves contain—besides tannic and gallic acids, quercetin, bitter extractive resin, gum, fatty matter, and salts of potassium and calcium—two glucosides, *arbutin,* $C_{12}H_{16}O_7$, and *ericolin,* $C_{34}H_{56}O_{21}$, and a crystalline principle, *urson,* $C_{20}H_{34}O_2$. There is present also a small amount of volatile oil which is probably a decomposition product of ericolin. The tannin is so abundant (6 or 7 per cent.) that the leaves are used for tanning in Russia.

Arbutin is widely diffused in the species of *Ericaceæ,* such as species of *Vaccinium, Rhododendron,* and *Chimaphila,* also in *Epigæa repens* L., and *Gaultheria procumbens* L. Arbutin occurs in long, acicular, colorless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, fusible at 195° C., without action on vegetable colors, and not precipitated by ferric salts or by lead acetate or subacetate. It is a glucoside, being resolvable by emulsin, or more rapidly by boiling with sulphuric acid, into glucose and *hydroquinone,* $C_6H_6O_2$ (*arctuvine* of Kawalier). Schiff has shown that arbutin is almost always accompanied by *methylarbutin,* $C_{12}H_{15}(CH_3)O_7 + H_2O$. This latter compound has been made synthetically by Schiff (*B. Chem. G.,* 1882, p. 1841) by acting upon arbutin with methyliodide and potassium hydroxide in methyl alcohol solution, and purely synthetically by Michael (*B. Chem. G.,* 1885, p. 118) by the action of methylhydroquinone and acetochlorhydrose. It is decomposed by dilute acids into glucose and methylhydroquinone. Upon heating 1 part of arbutin with 8 parts of manganese oxide, 2 parts of sulphuric acid, and 1 part of water, it gives off the penetrating odor of quinone. The aqueous solution is rendered blue by a small quantity of solution of ferric chloride and green by a larger quantity. It dissolves in sulphuric acid, forming a colorless solution, turning red after a short time; a trace of nitric acid turns this solution yellow-brown. A good test for arbutin is that of Jungmann: Phosphomolybdic acid added to an alkaline solution of arbutin gives a blue color.

A. G. Perkin has obtained from the leaves of uva ursi a yellow coloring principle of the composition $C_{15}H_{10}O_7$, crystallizing in glistening yellow needles. On fusion with alkali, phloroglucinol and protocatechuic acid were formed. Though resembling quercetin in these points, it forms deep green solutions with diluted potassium hydroxide. (*A. J. P.,* 1898, 584.) Shippee and Fogele (*Chem. News,* 1918, cxvii, 254) analyzed the fruit of uva ursi commonly known as *red bearberry* or *kinnikinic* and report protein 4 per cent., sugars (chiefly levulose) 21 per cent., a dark gummy substance and 2.9 per cent. of ash.

Uses.—Uva ursi is used to-day almost exclusively in the treatment of catarrhs of the urinary tract, especially *acute cystitis.* Although by some it is believed to exercise an astringent and alterative influence on these membranes, it is probable that its action is simply that of a mild antiseptic. Lewin (*V. A. P. A.,* 1883, xcii, p. 517) attributes its virtues to the arbutin which is decomposed in the system liberating hydroquinone. Bass, however (*Z. E. P. T.,* 1912, x, p. 120), is doubtful whether enough hydroquinone can appear in the urine to exercise any antiseptic effect. But whether or not its virtue is due to arbutin or some other principle, the clinical evidence is strong that uva ursi is a useful drug in these conditions. Formerly it was also employed in *gravel, nephritis, urethritis,* and *menorrhagia,* but has been largely abandoned. Because of the formation of hydroquinone in the body the urine often acquires a greenish color from the use of uva ursi.

Arbutin has been employed in medicine not only for its antiseptic effect but also as a diuretic in doses of from one to three grains (0.065–0.2 Gm.).

Dose, powdered uva ursi, from twenty grains to a drachm (1.3–3.9 Gm.), but the fluidextract is usually preferred.

Off. Prep.—Fluidextractum Uvæ Ursi, *U. S.;* Infusum Uvæ Ursi, *Br.;* Elixir Buchu Compositum (from Compound Fluidextract of Buchu), *N. F.;* Fluidextractum Buchu Compositum, *N. F.*

VACCINUM VARIOLÆ. U. S.

SMALLPOX VACCINE Vaccin. Var. [Virus Vaccinicum U. S. P. IX, Glycerinated Vaccine Virus, Jennerian Vaccine]

Vaccine Virus; Impfstoff, *G.;* Virus vaccin, *Fr.;* Vaccino, Virus di vacca, *It.;* Vacuna, *Sp.*

Though constantly used by the medical profession for more than a century, this article was first admitted into the United States Pharmacopœia in the Ninth Revision. Vaccination against smallpox is the oldest and the surest method of preventive medicine, directed against a specific disease. Its efficacy was first proven by Jenner in England in 1796, and soon corroborative evidence was supplied from America, notably by Waterhouse of Boston. Up to the middle of the nineteenth century, the vaccine material was commonly taken from the arm of a person previously vaccinated and thus carried on from patient to patient. At present the calf serves exclusively in this country as the animal for propagating the virus to be used on human subjects; the danger of transmitting some other latent disease of man at the same time is thus avoided. Other improvements which have occurred in the course of time are the use of the more potent pulp, instead of the lymph of the vesicle on the calf, and especially the use of glycerin as a preservative. The glycerin is allowed to act on the virus for a numer of days before use, and by this means the bacteria, normally present on the skin of the calf from which the virus is taken, are very greatly reduced in number. Phenol and ether have also been used to obtain a nearly sterile vaccine. The only form of dispensing now allowed is in the sterile capillary tube.

"Smallpox Vaccine consists of a glycerinated suspension of the vesicles of vaccinia or cowpox which have been obtained from healthy vaccinated animals of the bovine species. The vesicles must be removed and the vaccine must be prepared under aseptic conditions. The vesicles must be removed from the animal at the time of maximum potency, thoroughly triturated and made into a smooth suspension with an aqueous solution of glycerin. This solution shall not be acid to bromcresol purple T.S. or distinctly alkaline to phenol red T.S.

"Smallpox Vaccine must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The following precautions must be observed in licensed establishments.

"No vaccine shall be used from any animal having a communicable disease, other than vaccinia. Animals used for propagating Smallpox Vaccine must have been previously subjected to a tuberculin test and must have been held at least seven days in quarantine under daily veterinary inspection prior to vaccination. After the vaccine pulp is removed from each animal, a necropsy shall be performed, permanent records of which shall be kept. Each lot of Smallpox Vaccine shall be examined to determine its freedom from undue bacterial content and a special examination shall be made of each lot to determine the absence of tetanus organisms and other pathogenic anaerobes. Permanent records must be kept of these examinations. The finished product must be placed in sterile containers that comply with the requirements of the law and of the regulations established by the United States Public Health Service.

"Each package of Smallpox Vaccine must bear upon the label the name of the product, the name, address, and license number of the manufacturer, and a statement of the date beyond which the contents cannot be relied upon to yield their specific results. The label must also bear the lot number of the Vaccine, and directions concerning the storage of the package below 5° C.

"Smallpox Vaccine loses potency rapidly, even at moderate temperature. It must therefore be kept at the lowest possible temperature, preferably below 0° C., and never above 5° C." *U. S.*

The propagation of vaccine virus requires sterile laboratory equipment and careful technic throughout. The animals must be tuberculin tested, repeatedly inspected and kept very clean; the removal, grinding, and distribution of the vaccine into its final containers are strict aseptic operations.

Uses.—To appreciate what vaccination has done for mankind, it is necessary to consider the era before vaccination, when having had smallpox was one of the evidences of maturity, and the toll of lives yearly demanded by this disease was a constant drain on every class of humanity. In more recent times the regions where vaccination is little practiced are conspicuous for the number of pock-marked faces; opposition to vaccination was so general in Montreal that when in 1886 a Pullman car conductor brought smallpox from Chicago, an epidemic broke out which in nine months killed 3164 persons. As a contrast to this may be cited the experience of smallpox hospitals, where doctors, nurses, and attendants never having had smallpox are kept immune by vaccination. Smallpox among the unvaccinated is the most contagious disease known, yet vaccination is often too lightly regarded in that it is carelessly performed and no attention is given the patient after the operation. Any wound is liable to complications; a wound intentionally given should be particularly guarded against infection. Vaccination by scarification or cross-hatching, which forms an ulcerating area of appreciable extent—and the use of vaccination shields or other inappropriate after-care are the most frequent causes of sore arms. To vaccinate, the skin of the upper arm near the insertion of the deltoid muscle should be cleansed and dried. Soap and water followed by alcohol, or ether may be used for this purpose, but no stronger antiseptic should be applied. The cotton or cloth with which the skin is wiped should be sterile and nothing else allowed to touch the site. The capillary tube may be wiped with alcohol, the ends broken inside the bulb, and the glycerinated virus expelled by the bulb to form a line on the cleansed skin. Drawing the skin tight by grasping the arm beneath, a single incision about one quarter of an inch long and parallel with the arm is made through the virus. This incision may be made with a flamed needle or other sterile instrument and should penetrate the papillary layer, but preferably not draw blood. The virus should be thoroughly rubbed into the incision with a smooth sterile instrument, such as the side of the needle. No other incision or cross-scratching should be made unless there will be no opportunity for revaccination; in the latter case similar single incisions may be made on either side of the first and at least an inch away; other tubes should be used for this purpose. By this means the pustulation is limited so that large confluent crusts are not formed and deep ulceration with the tendency to secondary infection is avoided. Another method which produces even a smaller wound, but is surely successful only with very fresh virus is inoculation by the twisting abrasion. A dentist's drill (sterilized each time by flaming or other method) is used for this purpose. A slight twirling motion between the thumb and forefinger causes this instrument when pressed against the skin to give a shallow area denuded of epidermis, but without bleeding, no larger than a pinhead. To this the virus can be applied and rubbed in as above described. The vaccination area should dry (not in direct sunlight) for fifteen minutes or half an hour before being covered with clothing. The arm must be kept clean, dressed aseptically when the vesicle appears, and, when pustulation ensues, treated antiseptically. No dressing should be allowed to remain on the arm more than forty-eight hours. The arm should be seen by the physician on the third, sixth and ninth day at least, to determine the character of the reaction, and as often as may be necessary thereafter to insure rapid healing of the wound. It is preferable if the whole process can take place without the crust breaking. Vaccination is a surgical procedure and is worthy not only of the painstaking asepsis of a skilled physician, but of his intelligent after-care as well. If never previously vaccinated, the patient usually shows a papule about the fourth day, a vesicle about the fifth, and a pustule the eighth. Re-vaccination may be more rapid in its course, and correspondingly milder; in some cases a small papule is seen on the second day, subsiding without further progress. These abortive accelerated reactions may be taken as indicative of a degree of immunity.

The protection given by vaccination is relative, not absolute, and re-vaccination should be done when exposure to smallpox takes place or is threatened. All infants, except in the presence of eczema or marasmus, should be vaccinated before teething begins; re-vaccination should be performed before entering school and again at the age of fifteen.

Vaccine virus is the most rapidly deteriorating product likely to be carried by the pharmacist, and should be kept in the coldest part of an ice-box, at a temperature preferably below 0° C. and never above 5° C.

VALERIANA. U. S. (Br.)

VALERIAN Valer.

"Valerian consists of the dried rhizome and roots of *Valeriana officinalis* Linné (Fam. *Valerianaceæ*). Valerian contains not more than 5 per cent. of foreign organic matter and yields not more than 10 per cent. of acid-insoluble ash." *U. S.* "Valerian Rhizome is the dried rhizome and roots of Valeriana officinalis, *Linn.* Collected in the autumn." *Br.*

Valerianæ Rhizoma, *Br.;* Valerian Root; Radix Valerianæ Minoris, R. Valerianæ Sylvestris, R. Valerianæ Montanæ; Common, Garden, Cat's or Great Wild Valerian, All-heal, Garden Heliotrope; St. George's Herb; Summer Heliotrope, Herb Bennet, Vandal Root; Racine de Valériane, Valériane, *Fr.;* Radix Valerianae, *P. G.;* Wilde Baldrianwurzel, Baldrianwurzel, *G.;* Valeriana, *It.;* Valeriana (Rizoma de), *Sp.*

Official or common valerian (*Valeriana officinalis*) is a large, handsome, herbaceous plant, with a perennial rhizome, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stems are attached by short, broad sheaths; the radical leaves are larger and long petiolate. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-colored, quite fragrant, and disposed in terminal corymbs interspersed with pear-shaped bracts. The number of the stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris* L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves.

The valerian plant is cultivated to some extent in New England and New York, and on an extensive scale in England, and various parts of Europe and in Japan. In this country it will grow in light, well-prepared, and well-drained soil, and is propagated by dividing the roots in the fall and setting these portions in rows about two feet apart. (*D. C.*, lvi, p. 134.) In Europe it appears to be grown in a clayey soil. (*Pac. Pharm.*, vii, p. 297.) Mitlacher reports on the results of his experiments on the cultivation of valerian. (*Zeit. Oest. Apoth. Ver.*, l, p. 459.)

Valeriana mexicana DC.—According to the *Nueva Farmacopea Mexicana,* the roots of this plant contain a large percentage of valeric acid, which they yield readily and economically. In Mexican commerce they are said to occur in slices or fleshy disks about four centimeters or more in diameter, or in voluminous tubercles. Externally the color is grayish-yellow, internally yellow; the odor is strong and disagreeable, the taste bitter. R. McLaughlin (*A. J. P.*, 1893, 329) found 3.3 per cent. of oil in the Mexican valerian root. (See also *Schim. Rep.*, April, 1897.)

Japanese Valerian. Kesso Root.—This, formerly believed to be the product of *Patrinia scabiosæfolia* Link, is now said to be obtained from *V. officinalis* var. *latifolia* Miq. It yields a volatile oil. (*P. J.*, xx, 837; xxi, 1069.) The rhizome, sometimes known as *Valerianæ Radix Majoris,* is obtained from *V. Phu* L., of southern Europe, and western Asia. It is from 4 to 6 inches long, ½ inch in thickness, brown, annulated with numerous yellowish roots, and a feeble, valerian-like odor and taste.

The root should be collected in spring, before the stem begins to shoot, or in the autumn, when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous, long, slender, brittle, cylindrical, thick-barked rootlets, issuing from an erect tuberculated rhizome. The drug of commerce comes chiefly from England, Belgium and Germany.

Description and Physical Properties.—"*Unground Valerian.*—Rhizome upright, from 2 to 4 cm. in length, and from 1 to 2 cm. in diameter, usually cut longitudinally into 2 to 4 pieces; externally yellowish-brown or dark brown, upper portion with stem bases and frequently with a short horizontal branch or stolon, and from the outer surface arise numerous slender, brittle roots; fracture of rhizome short and horny; internally light brown, with a thick bark and narrow central cylinder; odor of valeric acid, becoming stronger upon aging; taste sweetish, camphoraceous and somewhat bitter.

"*Structure.*—Root with a single epidermal layer of papillose cells, some being modified to root hairs; a hypodermal layer bearing secretion cells with suberized walls and usually containing numerous small globules and occasionally small prismatic crystals; cortical parenchyma, the cells filled with starch, some of the cells near the hypodermis containing a few oil globules; an endodermis of thin-walled cells surrounding a pericambium; a central cylinder with usually 3 to 5 fibro-vascular bundles. Older roots with a large pith of starch-bearing parenchyma, a secondary thickening in the fibro-vascular bundles and a periderm of a few layers of cells. Rhizome with a thin periderm, a cortical parenchyma with scattered fibro-vascular bundles, a layer of altered cells of the endodermis, numerous, more or less twisted, collateral, fibro-vascular bundles and a large pith.

"*Powdered Valerian.*—Light brown to grayish-brown; starch grains numerous, from 0.003 to 0.020 mm. in diameter, spherical, plano-convex, polygonal, 2- to 4-compound and each usually with a central cleft; tracheal fragments, the walls having simple and bordered pores or scalariform and reticulate thickenings, accompanied by narrow fibers, the walls of the latter being thin, porous, and strongly lignified; occasional fragments of epidermis with root-hairs, and fragments of cork." *U. S.*

"Rhizome short, erect, entire or sliced, dark yellowish-brown externally, whitish internally. Roots numerous, about seven to ten centimetres long, of the same color as the rhizome, slender, brittle. Strong, characteristic, disagreeable odor; taste unpleasant, camphoraceous, slightly bitter. Ash not more than 10 per cent." *Br.*

The roots of *Valeriana Phu* L., and *V. dioica* L., are said to be sometimes mingled with those of the official plant. According to Ebermayer, in Germany various ranunculaceous roots are a dangerous adulterant of valerian; they may be readily detected by their want of the peculiar odor of the official root. According to M. O. Raveil, the valerian in the markets of Paris has been largely adulterated with the roots of *scabious* (*Scabiosa succisa* L., and *S. arvensis* L.). They are shorter than the genuine root, with larger radicles, less rough, little or not at all striated, very brittle, with a white amylaceous fracture. The roots are inodorous in themselves, but are very apt to acquire odor from contact with the valerian. (*J. P. C.*, xxvi, 209.)

The odor in the fresh root is pleasantly aromatic, but in the dried is stronger and less agreeable. Cats are strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic.

Trommsdorff found it to consist of 1.2 parts of volatile oil, 12.5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions, 18.75 of gum, 6.25 of a soft odorous resin, and 63 of lignin. Of these constituents the most important is the *volatile oil.* This occurs only in the subepidermal cells of the root. It is lævorotatory, of a pale greenish color, of the sp. gr. 0.934, with the pungent odor of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Schimmel & Co. (*Schim. Rep.*, April, 1897) summarize their researches upon valerian oil from different sources: In the oil from Dutch and Thuringian roots, the amount varying from 0.5 to 1 per cent., they find pinene, camphene, borneol, bornyl formate, bornyl acetate, and *bornyl isovalerate,* together with a sesquiterpene and an alcohol, $C_{15}H_{26}O$. In the oil from Japanese roots (amounting to from 6 to 6.5 per cent.), they find pinene, camphene, dipentene, terpineol, borneol, bornyl acetate, bornyl isovalerate, and *kessyl acetate.* Trommsdorff ascertained the existence in the oil of *valeric acid.* (See Part II.) The acid does not pre-exist in the oil, but is produced by the decomposition of its borneol ester. Söderberg (*P. J.*, 1918, ci, 120) assays valerian root by steam distillation, neutralization of the distillate, shaking out with ether, distilling the ethereal solution and drying the oily residue in a desiccator. He reports from 2.00 to 3.18 per cent. of oil present.

Goris and Vischniac (*C. R. A. S.*, 1921, clxxii, 1059) confirm the statement of Chevalier that valerian root contains two alkaloids, of which one is soluble in ether (*chatinine*) and the other insoluble in ether (*valerine*) but soluble in chloroform.

Uses.—Valerian is used as a sedative to the higher nerve centers in conditions of *nervous unrest, hysteria, hypochondriasis, neuralgic pains,* and the like. The virtues of the plant seem to depend chiefly on the esters of valeryl which are contained in the volatile oil. According to Chevalier (*Nouv. Rem.*, 1912, xxix, p. 169), the volatile oil of valerian is a depressant to the whole central nervous system, including both the motor and psychical centers of the brain and the motor cells of the spinal cord. The experiments of Macht and Giu (*J. P. Ex. T.*, 1921, xviii, p. 361) upon rats suggest that the cerebral sedative action of valerian is a reflex from the olfactory organs. The esters contained in this drug are unstable bodies and in the process of drying largely oxidized with the formation of valeric acid. As the latter is practically without physiological action much of the virtue of the plant is lost during the drying process. Probably for this reason preparations of this drug are very uncertain in their activity and valerian has largely fallen into disrepute. Chevalier has introduced the juice of the fresh root which he asserts is a valuable remedy not only for the conditions mentioned above, but even as a narcotic in *insomnia* and an anticonvulsant in *epilepsy.* The dose of this juice, which has been introduced under the name of *energetene of valerian,* is one to three coffee-spoonfuls. It appears also to have some slight influence upon the circulation, slowing the heart and increasing its force, and causing a rise in blood pressure, and has been used in the treatment of *cardiac palpitations.*

Dose, twenty to forty grains (1.3–2.6 Gm.). The dose of the oil of valerian, which is occasionally employed, is four to five minims (0.25–0.3 cc.).

VALERIANÆ INDICÆ RHIZOMA. Br.

INDIAN VALERIAN RHIZOME

"Indian Valerian Rhizome is the dried rhizome and roots of Valeriana Wallichii, *DC.*" *Br.*

Valeriana Wallichii is a perennial herb growing in the temperate Himalayas and in the Khasia Mountains. The rhizome is more largely used as a perfume than in medicine. It is used in preparations for the hair and the dried rhizome is used as an incense. It is officially described as follows: "Rhizome curved, about five centimetres long, from five to ten millimetres thick, dull brown, with raised transverse leaf-scars, numerous prominent root-scars and a few thick roots; the crown bearing the remains of petioles. Fracture short. In transverse section, dark with a large pith and diffuse ring of small wood-bundles. Strong, characteristic, disagreeable odor; taste unpleasant, camphoraceous." *Br.*

According to Lindenberg (*Ph. Z. R.,* 1886), Indian valerian is practically identical in its composition with the European drug, but contains a slightly larger amount of volatile oil. It may be employed in the same class of cases as valerian.

Off. Prep.—Tinctura Valerianæ Indicæ Ammoniata, *Br.*

VANILLA. N. F.

VANILLA Vanill. [Vanilla Bean]

"Vanilla is the cured, full-grown, unripe fruit of *Vanilla planifolia* Andrews (Fam. *Orchidaceæ*). Vanilla should be preserved in a cool place where it will not become brittle. Vanilla which has become brittle should not be used." *N. F.*

Vanille, *Fr. Cod.;* Fructus Vanillae, *P. G.;* Vanille, *G.*

Vanilla planifolia is a tall, perennial climbing epiphyte, with a very long, smooth, dark green stem, much branched, and furnished at the nodes with aerial roots, which cling to the tree or the wooden framework supporting the plant. The dark green, tough leaves are alternate, oval, sessile, attenuate at the apex, fleshy and veinless. The pale greenish-yellow, sessile flowers are about two inches in diameter, and occur in loose, axillary racemes of twenty or more blossoms. The fruit is a slender capsule, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds.

This plant is a native of Mexico, but is now widely cultivated throughout the tropics and in greenhouses. Mexico, the Seychelles, Réunion and Society Island yield the bulk of the beans of commerce. It does well from the sea-level up to two thousand feet of altitude, requiring for its perfection, however, a moist, hot climate, with an habitual dry summer spell which seems to be necessary to bring good flowering. It is propagated by means of cuttings, sometimes two or three feet in length, but preferably from ten to twelve feet long, taken from growing shoots; these are planted after the dry season is over and should produce flowers in two years. Preferably placed upon trees, but sometimes on long stakes, trellises, wire supports, etc., the slip is placed with one end on the ground, covered with leaves or some light top dressing. In many cases the vines are planted so closely as scarcely to leave room for cultivators to pass, but it has been found that under these circumstances the vanilleries are especially liable to destructive fungous diseases. As the flower does not fertilize itself, fertilization (pollination) by hand is necessary; it is usually performed by women and children. In most localities not more than thirty fertilized flowers should be left to a plant. The pods reach their full size in from five weeks to eight months, according to the altitude of the locality and to the amount of shade. The first indication of ripening is a slight yellowing of the whole pod; as soon as this occurs the pods should be picked, and sorted, and the curing process commenced. If left to ripen further the pods are prone to split and otherwise deteriorate. For the purpose of curing them the pods are kept in a heated room for some days, then transferred to a cooler one and finished at ordinary temperature. During the process, which lasts some months, there is a loss of 70 to 80 per cent. of weight. For details as to culture, see articles by S. J. Galbraith in *Bulletin* 21, 1898, U. S. Department of Agriculture, Division of Botany, and by A. Franchère, *Bul. Econ. Gouvt. Gen. Madagascar,* vol. ii, No. 2, p. 122, 1914. The practice of curing the beans by placing them under blankets in the sun is still in vogue, but that of using a regulated artificial heat is more certain, and it is the modern method.

When thoroughly cured the beans are sorted according to length, those that have split or become otherwise defective being separated. They are then tied into bundles, which are wrapped in sheet lead or placed in small metallic boxes. In doing this it is essential that the bundle be wrapped in a thin vegetable parchment paper, as chemical action occurs when the beans come in contact with the metal.

Fruits which have not been picked early enough are inferior and are frequently cut into short pieces and sold as "cuts." If by chance the fruit should be picked too early the quality of the resulting product is distinctly inferior. The fruit as first picked has no aroma, the *vanillin* during the process of curing being produced from the glucoside *coniferin* in the interior of the fruit.

The cultivation of vanilla has extended from Mexico and South America throughout the tropics, so that at present, although the wild plant is abundant in the Mexican States of Vera Cruz and Oaxaca the vanilla of the markets comes almost exclusively from vanilleries. Holland is supplied from Java plantations; France from Tahiti, Madagascar, Réunion, Guadeloupe, and other of her colonies. From Mauritius and the Seychelles the product goes to London. In the markets most of the varieties are known by the name of the country in which they are produced. The finest of the varieties is the Mexican, although of recent years the Bourbon beans have so improved that they almost rival it in strength and flavor.

Of *Mexican vanilla,* the first quality occurs in pods from 15 to 20 cm. long, flattened, 6 to 8 mm. in diameter, with the lower end slightly attenuated, the upper end gradually tapering for about a quarter of the length of the pod, usually curved and slightly twisted near the point. The color is dark brown, the pods fairly plump, the surface ridged longitudinally, and with an incrustation of fine crystals beginning at the ends, gradually extending; when fresh somewhat viscid, but always roughish to the touch. For an interesting account of the Mexican vanilla plant by Charles E. Hires, see *A. J. P.,* 1893, 576. Cunningham states that the best quality of Mexican beans are those plucked in January and February but that much of the crop consists of beans plucked in October and November. Four classes of Mexican beans occur in commerce, viz., large-fine, small-fine, zacate and basura.

Of the Mexican vanillas the most valuable variety is the *papantha* bean, called *ley,* or *vainilla mansa* by the Spaniards; it consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odor, and a warm, aromatic, sweetish taste. The interior pulp portion is most aromatic. In it are more or less numerous, minute crystals. Another variety, called *vainilla simarona* by the Spaniards, is smaller, of a lighter color, and less aromatic. The pods are said to be very dry and to contain no vanillin. According to Schiede, it is yielded by a distinct species, the *Vanilla sylvestris* Schiede. A third variety is the *vainilla pompona* of the Spaniards (*boba vainilla,* or *plátano vainilla*). In this, the pods are from 12 to 18 cm. long, from 12 to 18 mm. broad, shaped somewhat like a plantain, almost always open, very dark brown or nearly black, soft, viscid, and of a strong odor. Schiede states that it is the product of the *Vanilla Pompona* Schiede. The variety *vainilla vezacate* is said to be derived from pods gathered long before maturity. (*Nueva Farmacopea Mexicana.*) The *vainilla pompona* of the Spaniards is evidently the *vanillons* of European commerce, which are usually from 10 to 13 cm. long and from 15 to 25 mm. in diameter, frequently sharply angled, brown to red-brown in color, usually split open and free from efflorescence. Owing to the transverse markings by twine with which they have been wrapped during the process of curing, the beans have a peculiar twisted appearance. Their odor, which resembles that of heliotrope, is due to the presence in them of *heliotropin,* in lieu of *vanillin.*

Bourbon or *Indian Ocean vanilla,* produced in the Isle of Réunion, resembles Mexican vanilla, but is scarcely so long in the tapering portions, is of a dark brown almost black color, is not so firm as the Mexican, has the surface smooth and waxy, and soon becomes covered with a coating of acicular crystals known as "frost." The odor of this vanilla is said to resemble that of Tonka bean rather than that of Mexican vanilla.

The *Seychelles* and *Mauritius vanilla* (*inferior Bourbon* of the trade) has the pods about six inches in length, not over a quarter of an inch in width, and characterized by the pale color, the faint odor, and a smooth but not waxy surface.

South American or *Guadeloupe vanilla* resembles the Mexican bean, but is usually recognizable, when the bean is entire, by the latter being broad and flattened, usually half an inch or more wide, slightly tapering at the lower end, and at the upper sharply attenuated an inch or so at the point. It has a reddish brown color, and is of a rank odor. It is very pulpy, with a surface intermediate in feel between the Bourbon and the Mexican, and having but few crystals. One variety of this vanilla, sold under the name of *vanillons,* has the odor of heliotrope and is much used by perfumers and tobacco manufacturers.

Tahiti vanilla has its pods from six to seven inches long, flat, from three-eighths to half an inch wide, with a reddish-brown color. They are almost destitute of vanilla flavor, and have an odor suggesting heliotrope. It is said they contain piperonal and also vanillin. According to Constantin and Bois (*P. J.,* 1915, xcv, 360), there are two other sorts of vanilla grown in Tahiti; one is from a plant that they regard as a variety of *V. planifolia* from which it differs in the characters of foliage and the shape of the labellum in the flower; they propose to call it *V. planifolia* var. *Augusta.* The third sort has a flavor resembling that of the Java bean and a pleasant odor with an after-taste of heliotrope. They have not seen the flowers of this.

Java vanilla, which is almost exclusively consumed in Holland, has a pod from four to six inches long, with a flavor as fine as that of the Mexican bean, and a much stronger odor.

Description and Physical Properties.—"*Unground Vanilla.*—Fruit linear, flattened, from 15 to 35 cm. in length and from 5 to 9 mm. in width; apex terminating in a flat circular scar; gradually tapering, more or less bent and curved or hooked at the bases, or in the Tahiti variety, broad in the middle and tapering towards either end, the base closely resembling the summit; externally blackish brown, longitudinally wrinkled, moist-glossy; occasionally with an efflorescence of vanillin in the form of acicular crystals or monoclinic prisms; frequently with narrow, elliptical or irregular, more or less wrinkled, dark-brown patches of cork, occasionally split into three parts near the tip, flexible and tough, one-celled, containing a blackish brown pulp and numerous blackish brown seeds; the latter being flattened, irregularly triangulate or nearly circular in outline; reticulate and varying from 0.25 to 0.3 mm. in diameter. Odor and taste characteristic and very agreeable.

"*Structure.*—Epidermis with a somewhat thickened outer cuticularized layer having occasionally rounded or conical masses of an excretion of a gum-like substance; a layer of collenchyma of one or two rows of cells; a thick sarcocarp composed of parenchyma cells in which is imbedded an interrupted circle of fibrovascular bundles; the parenchyma cells are deeply undulate in outline and usually contain a thin protoplasmic layer enclosing numerous oily globules or may contain bundles of raphides of calcium oxalate; the individual crystals varying from 0.2 to 0.4 mm. in length; some of the parenchyma cells are specially modified and distinguished by their somewhat thickened walls with long, oblique, slit-like pores or the thickening may extend in the form of broad, spiral bands; in the fibro-vascular bundles the phlœm is central, being more or less surrounded by a few tracheæ, the walls possessing slit-like pores or spiral thickenings, and at the outside of the bundle is a closed circle of fibers, the walls being thin, strongly lignified, provided with numerous, transverse, simple pores, the outer wall of the outer row of fibers being irregular or sinuate; from the inner walls of the endocarp arise the placentæ bearing numerous brownish red or blackish seeds, and from the cells of the endocarp also arise numerous long, nearly straight hairs, the ends being rounded, the hairs being more or less matted together by a gummy or resinous mass in which some of the seeds are held; in mounts made in chloral hydrate T.S. or potassium hydroxide T.S., the immature, brownish red seeds show a deeply reticulate seed-coat, with cells of an oblong-polygonal form in surface view.

"Place a few of the crystals, occurring as an efflorescence on the fruit, on a microscope slide or watch crystal and add a drop of phloroglucinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from *benzoic acid*). The amount of extractive yielded to dilute alcohol should not be less than 12 per cent." *N. F.*

A characteristic test for the vanillin crystals which occur as an efflorescence on the fruit is as follows: On a microscope slide or watch crystal, place a few crystals and add a drop of phloroglucinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from *benzoic acid*). The amount of extractive which vanilla of good quality yields to dilute alcohol should not be less than 12 per cent. Nor should it yield more than 6 per cent. of ash.

Vanilla beans from which the vanillin has been removed by means of a solvent are sometimes offered for sale. The fraud is to be detected by the absence of flavor and odor. Such beans, and also beans of an inferior quality, are sometimes "improved" in appearance and in odor by the use of benzoic acid. For the detection of this fraud the pharmacist should avail himself of the fact that while the crystals of benzoic acid are flattened and rhomboidal and generally lie upon the bean, those of vanillin are usually acicular and stand out at right angles from the surface of the fruit. The absence of the crystalline coating on the vanilla beans seems to be no proof of inferiority, for Henri Lecomte affirms that it is not rarely absent in the best Mexican bean. (*B. Sc. Pharm.*, 1901.)

Constituents.—The vanilla fruit when fresh possesses none of the pleasant aroma which we associate with the fruit, the odor being developed during the process of curing. There is present in the fruit the glucoside *coniferin* and two ferments. Under the action of these successively, the coniferin is first changed into *coniferyl alcohol* and thence into vanillin. Coniferin has been separated in the pure state not only from this plant but from several species of pine trees (see *Pinus Strobus*). Coniferin forms white crystalline needles having a composition of $C_{16}H + 2H_2O$. These are efflorescent in dry air and when anhydrous have a melting point of 185° C. Coniferin is practically insoluble in cold water, but soluble in alcohol and slightly so in hot water, its solution having a bitter taste. It may be hydrolyzed by either sulphuric or chromic acid as well as by the ferments found in the vanilla bean. (See *Vanillinum.*) H. Lecomte (*J. P. C.*, 1903, 343) studied the conditions which bring about the formation of vanillin. According to his researches, there exist in the vanilla plant two ferments, which differ in a marked degree from each other in their functions. The one, an oxydase, is present in the individual organs of the plant, such as the leaves, shoots and their aqueous extracts, in the green and ripe fruit, and in the prepared commercial fruit. The second ferment is contained in the sap of the vanilla, and acts as a hydrolyzing ferment. Both ferments, the oxydase as well as the one possessing the hydrolytic action, appear to be necessary for the formation of vanillin in the plant, and their action may possibly be explained thus: During the preparation the coniferin produced by the plant is split up into glucose and coniferyl alcohol. This process would explain also the occurrence of grape-sugar in vanilla. The oxydase then converts the coniferyl alcohol into vanillin.

Tiemann and Haarmann obtained from Mexican vanilla 1.69 per cent. of vanillin, from Réunion vanilla 2.48 per cent., from Java vanilla 2.75 per cent.

Uses.—Vanilla is used solely as a flavoring agent; it is an ingredient of several N. F. preparations.

Vanilla Poisoning.—Cases of violent gastro-intestinal irritation from eating vanilla ices have been reported. Most of these undoubtedly were due to tyrotoxicon, a ptomaine produced in decomposing milk; but if the one reported by Rosenthal (*P. J.*, xv, p. 24) be accurately stated it must be allowed that in some instances the vanilla itself is at fault. In this connection the reports of Claverie (*J. P. C.*, Supp. 1908, xxv) of violent dermatitis in workmen handling vanilla beans is of interest. He attributes the symptoms to the oily exudate of the vanilla pods.

Off. Prep.—Tinctura Vanillæ, *N. F.*

VANILLINUM. U. S.

VANILLIN Vanillin.

"Methylprotocatechuic aldehyde [$C_6H_3.CHO.OCH_3.OH$ 1:2:4]." *U. S.*

Vanilline, *Fr. Cod.;* Aldehyde Vanillique, *Fr.;* Vanillin, Vanillekampher, *G.*

Preparation.—Vanillin was first obtained from vanilla by Gobley, who, by exhausting vanilla with 85 per cent. alcohol, evaporating the resulting tincture to an extract, softening this with water, and agitating in a flask with ether so long as it gave color to that fluid, then evaporating the ethereal liquid and treating the residue with boiling water, obtained on the evaporation of the water a crop of crystals having the odor of vanilla. It is now recognized to be the methyl ether of protocatechuic aldehyde, $C_8H_8O_3$, and is widely diffused in the vegetable kingdom; it occurs in the sugar beet, the flower of the potato, and the woody tissues of several plants. Vanillin oxidizes slowly in damp air to *vanillic acid,* $C_8H_8O_4$; when heated with diluted hydrochloric acid to 200° C., it breaks up into methyl chloride and protocatechuic acid.

Vanillin was first synthetically prepared from *coniferin,* $C_{16}H_{22}O_8$, a principle discovered by Hartig in the cambium layer of coniferous trees and later discovered in *asparagus.* When coniferin is hydrolyzed it yields dextrose and *coniferyl alcohol,* $C_{10}H_{12}O_3$. Either *coniferin* or coniferyl alcohol yield *vanillin* when subjected to oxidation by the action of sulphuric acid and potassium dichromate. The reaction in the latter case is as follows:

$$C_{10}H_{12}O_3 + O = C_8H_8O_3 + C_2H_4O$$

Vanillin is also produced synthetically from eugenol, the chief constituent of oil of cloves, by the action of acetic anhydride, to convert it into acetyl-eugenol, $C_{10}H_{11}(C_2H_3O)O_2$. This is then oxidized by means of potassium permanganate which results in the production of acetyl-vanillin, which is later converted into vanillin by the action of sodium hydroxide.

Description and Physical Properties.—"Fine, white, or only very slightly yellowish, needle-like crystals, having an odor and taste resembling vanilla. One Gm. of Vanillin is soluble in 100 cc. of water and in about 20 cc. of glycerin, at 25° C. One Gm. is soluble in 16 cc. of water at 80° C. It is freely soluble in alcohol, chloroform, and ether.

"Vanillin is easily dissolved by aqueous solutions of alkali hydroxides, and from these solutions, when not too dilute, it is precipitated at once by the addition of acids. Vanillin melts between 80° and 82° C. Its aqueous solution is acid to litmus paper and is optically inactive. A saturated aqueous solution of Vanillin gives a blue color with ferric chloride T.S. On boiling the mixture, the blue color changes to brown, and on cooling, a white, or nearly white precipitate of dihydrodivanillin separates. Vanillin is extracted completely from its solution in ether by shaking with a saturated, aqueous solution of sodium bisulphite, from which it is precipitated by the addition of sulphuric acid. A cold aqueous solution of Vanillin gives with lead acetate T.S. a white precipitate of a lead compound of vanillin, which is soluble in hot water.

"Ash: not more than 0.05 per cent. Warm 0.1 Gm. of Vanillin with a concentrated alcoholic solution of sodium hydroxide, add a drop of chloroform, and again warm: the odor of phenylisocyanide is not perceptible (*acetanilid*).

"Preserve in well-closed containers, protected from light." *U. S.*

A new qualitative test and colorimetric method for the quantitative estimation of vanillin has been described by Clarence Estes (*J. I. E. C.*, 1917, ix, p. 142) which depends upon the effect of the addition of solution of acid nitrate of mercury under certain conditions. A violet to violet-red color is produced, which is unlike that produced by any organic compound likely to be present as an accidental or interfering substance. The results of the application of the author's method directly to flavoring extracts of known composition agreed closely with the gravimetric figures.

Uses.—According to Grasset, vanillin produces in frogs spinal convulsions, followed by paralysis due to a direct action upon both the spinal cord and motor nerves. It has been suggested as a stomachic and excito-motor given in doses of three-fourths of a grain (0.048 Gm.).

(*A. Pharm.*, Aug., 1896.) Neither it nor vanilla, however, are used for other than flavoring purposes. The fact that while the vanilla beans have steadily risen in price for a number of years that of the artificial vanillin has enormously fallen, indicates that as a flavoring agent vanillin is not equal to the natural product. It is said that articles flavored with it leave a peculiar, disagreeable after-taste and retain their flavor only a very short time.

VERATRINA. N. F.

VERATRINE Veratrin. [Veratria]

"A mixture of alkaloids obtained from the seed of *Asagræa officinalis* (Chamisso and Schlechtendal) Lindley (Fam. *Liliaceæ*)." *N. F.*

Vératrine Officinale, *Fr. Cod.;* Veratrinum, *P. G.:* Veratrin, *G.;* Veratrina, *It.*, *Sp.*

Veratrine has been deleted from the U. S. X and the Br. 1914, but has been introduced into the N. F. A process for its preparation will be found in the *U. S. D.,* 19th ed., pp. 1327 and 1328.

For description of the plant from which this substance is obtained see *Sabadilla,* Part II.

Veratrine is a mixture of all the alkaloids of sabadilla seeds. (See *Sabadilla,* Part II.) These, as far as determined at present, are: *cevadine* (*crystallized veratrine*), $C_{32}H_{49}O_9N$; *cevine* (*sabadinine*), $C_{27}H_{43}O_8N$; *veratridine* (*amorphous veratrine*), $C_{37}H_{53}O_{11}N$; *cevadilline* (*sabadilline*), $C_{34}H_{53}O_8N$; and *sabadine,* $C_{29}H_{51}O_8N$. Of these alkaloids the most important, from the therapeutic standpoint at least, appear to be cevadine and veratridine; the other alkaloids being much less active physiologically. Wright and Luff (*Tr. Chem. Soc.,* 1879, xxxv, 425) have found about 0.1 per cent. of cevadine. According to MacBeth and Robinson (*Tr. Chem. Soc.,* 1922, cxxi, p. 1574), its anhydrous crystals melt at 205° C.; it is insoluble in water but soluble in hot alcohol, their solutions being dextrorotatory. Veratridine is an amorphous varnish-like substance with a melting point of 180° C. It may be separated from the other alkaloids by precipitating an ethereal solution of the latter with light petrolatum. For further information concerning these alkaloids consult Freund (*B. Chem. G.,* 1899, xxxii, 800 and 1904, xxxvii, 1946); Frankfortes (*Am. Chem. J.,* 1898, xx, p. 361) and Hess and Mohr (*B. Chem. G.,* 1919, lii, 1984).

Two acids have also been found in sabadilla—the *sabadillic* or *cevadic acid* of Pelletier and Caventou, forming needle-like crystals fusing at 20° C., and the *veratric acid* of Merck, which Koerner showed to be dimethylprotocatechuic acid.

Description and Physical Properties.—"Veratrine is a white, or grayish white, amorphous powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane. *Great caution must be used in handling it.* It is slightly hygroscopic. One Gm. of Veratrine dissolves in 1760 cc. of water, 2.8 cc. of alcohol, 0.7 cc. of chloroform, and in 4.2 cc. of ether at 25° C.; also in 1345 cc. of water at 80° C.; insoluble in petroleum benzin.

"Its alcoholic solution is alkaline to moistened litmus paper. Triturate about 0.05 Gm. of Veratrine with 2 cc. of sulphuric acid in a glass mortar; the yellow or orange-red solution exhibits by reflected light a greenish fluorescence, which becomes more intense upon the addition of an equal volume of sulphuric acid. Upon standing, the solution gradually assumes a deep red color. Sulphuric acid, when heated with Veratrine, gives a cherry-red color. Sulphuric acid added to a mixture of one part of Veratrine and six parts of sucrose produces a green color which changes to blue, and finally the mixture becomes colorless. No weighable ash remains on incinerating 0.1 Gm. of Veratrine. An alcoholic solution of Veratrine (1 in 20) remains clear after the addition of platinic chloride T.S. (*Various foreign alkaloids.*)

"Preserve it in well-closed containers, protected from light." *N. F.*

Uses.—Probably because of its unfortunate name it has been assumed by some that veratrine represents the therapeutic virtues of veratrum. Its physiological action, however, differs greatly from that of veratrum, and if it possess any therapeutic usefulness it is certainly not for the conditions for which veratrum is employed.

Veratrine is an intense local irritant and somewhat locally anesthetic. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced and still more rarely an eruption upon the skin, but generally no decided signs of inflammation are evinced. When taken into the mouth it produces an almost insupportable sense of acrimony, and snuffed up the nostril it produces violent sneezing, and when taken into the stomach in large doses it causes violent vomiting, serous purging with intense burning in the mouth and throat and general muscular weakness. It is a powerful muscle poisoning and if given in sufficient dose in the lower animals it causes an extraordinary prolongation of the contraction of the striated muscles; the time required for relaxation of voluntary muscles may be 20 or 30 times as long as normal. A similar influence is exerted upon the ventricular muscles, at least in the frog, but the slowing of the heart rate seen in warm blooded animals seems to be due chiefly to stimulation of the cardio-inhibitory center. Death in mammals is generally due to depression of the respiration.

The only justifiable therapeutic use of veratrine is as an anodyne counter-irritant in *neuralgias* and various forms of *arthritis.* Even for this purpose it has no advantages sufficient to offset the dangers of systemic poisoning which might follow from its absorption.

Dose, one-thirtieth of a grain (0.002 Gm.).

Off. Prep.—Oleatum Veratrinæ, *N. F.;* Unguentum Veratrinæ, *N. F.*

VERATRUM VIRIDE. U. S.

VERATRUM VIRIDE Verat. Vir. [Green Hellebore, American Hellebore]

"Veratrum Viride consists of the dried rhizome and roots of *Veratrum viride* Aiton (Fam. *Liliaceæ*). Veratrum Viride contains not more than 5 per cent. of its stems or other foreign organic matter, and yields not more than 4 per cent. of acid-insoluble ash." *U. S.*

Big or False Hellebore, Swamp Hellebore, Indian Poke, Itch-weed, Tickle-weed, Bugbane; Vératre vert, *Fr.;* Grüner Germer, *G.;* Vedegambre verdo, *Sp.*

In the several revisions of the U. S. Pharmacopœia, *veratrum* has been handled in a vacillating manner. In 1880 and 1890 the drug was restricted to that obtained from *V. viride.* In 1900 both *V. viride* and *V. album* were recognized, this being done for reason of the large importations of *Veratrum album,* there being no practical method of distinguishing between these two drugs. The U. S. Pharmacopœia IX wisely restricted the definition, in the interest of uniform medicine, to *V. viride* and the present revision continues the distinction. This, however, may offer some practical commercial difficulties as it is not always easy to differentiate its substitution by *V. album,* and certainly it is almost impossible to detect an admixture with the European drug.

That the two species are very closely allied, and the two rhizomes histologically, chemically, and toxicologically very similar is indisputable, but similarity is not identity. The European plant seems to be more actively poisonous than is the American, and has been said by some chemists to contain a larger proportion of the alkaloids. It usually also has a distinctly greater action upon the intestinal tract and it is probable that the proportionate amounts of the alkaloids differ in the two species. The conclusions reached in an elaborate physiological research made by H. C. Wood and H. C. Wood, Jr., for the Committee of Revision of the U. S. VIII (*A. J. M. S.,* May, 1899) was that the drugs can scarcely be distinguished physiologically, but that the European plant is more likely to disturb the intestines and that in the absence of any cogent reason for recognizing *V. album, Veratrum viride* should alone be retained.

The American hellebore, *Veratrum viride,* has a perennial, thick, fleshy rhizome, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish roots. The stem is annual, cylindrical, striated, pubescent, and solid, from three to six feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, thus affording it a sheath for a considerable portion of their length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied by a downy, pointed bract, much longer than its pedicel. The perianth consists of six oblong or oblanceolate, acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The ovary is ovoid, tricarpellary; styles three and persistent. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those below fruitful. The fruit is a three-lobed capsule, three-celled, and containing flat imbricated seeds. This indigenous species of veratrum inhabits swamps, wet meadows, and the banks of mountain streamlets. It is more abundant northward, but reaches as far south as Georgia. From May to July is the season for flowering. It is doubtful whether the rhizome should be collected in autumn or just before flowering. It should be thoroughly dried and carefully preserved, as otherwise it deteriorates.

The commercial supplies of the drug are obtained from North Carolina, Virginia, Illinois and Michigan.

Veratrum album L. (*V. viride* Roehl., but not *V. viride* Aiton.).—The specific difference between this plant, which is a native of Europe and northern Asia, and *V. viride* of North America has been questioned by various botanists, but prominent taxonomists still regard the two species as distinct. (See *Index Kewensis;* also Engler and Prantl.) *V. album* resembles closely the American species, but is distinguished by its smaller leaves by possessing flowers with shorter pedicels and ovate perianth segments. The rhizome of *V. nigrum* of central Europe is said to be sometimes substituted for that of *V. album,* but is much smaller. According to the Pharmacographia, that of the Mexican species, *V. frigidum* Schl., exactly resembles that of *V. album.*

Description and Physical Properties.—"*Unground Veratrum Viride.*—Rhizome more or less conical, from 2 to 7 cm. in length, from 1.5 to 3 cm. in diameter, externally light to dark brown or brownish-black; frequently bearing at the summit numerous, thin, closely-arranged leaf bases, otherwise rough and wrinkled and somewhat annulate from scars of bud scales; inodorous; taste bitter and acrid. Roots numerous, nearly cylindrical, from 3 to 8 cm. in length and from 1 to 4 mm. in diameter, usually brittle, whitish, and more or less starchy.

"*Structure.*—The rhizome shows an outer layer of brownish cork-like cells; parenchyma containing raphides of calcium oxalate and starch; a continuous layer of endodermal cells; vascular bundles arranged in interrupted circles, single bundles scattered throughout the central parenchyma and also in the cortex. The root shows epidermal cells with lignified thickened outer and radial walls; parenchyma similar to that of rhizome; endodermal cells with inner and radial walls thickened and slightly lignified, with U-shaped cavity about one-third the cell width.

"*Powdered Veratrum Viride.*—Grayish-brown to dark brown, strongly sternutatory; starch grains numerous, from 0.003 to 0.020 mm. in diameter, spherical or ellipsoidal, single or 2- to 3-compound; raphides from 0.015 to 0.150 mm. in length; tracheæ scalariform or reticulate, often with lemon-yellow contents and associated with slightly lignified porous fibers; cork fragments few, reddish-brown or brownish-black." *U. S.*

It has been asserted that the color of *V. album* is much lighter than that of *V. viride,* but this certainly is practically incorrect, however it may apply to carefully preserved specimens. Very commonly the roots have been removed from commercial *V. album,* while in America they are generally allowed to remain on the rhizomes. According to R. H. Denniston, no microscopic differences can be detected in the rhizomes, but in the roots distinction is possible owing to the fact that directly beneath the epidermis in the *V. viride* the collenchyma region consists of but two or three rows of large, irregular and distorted cells, while in *V. album* this region is generally made up of seven to eight rows of rounded, thicker-walled and smaller cells, which are not in the least distorted. Any such test is, of course, inapplicable to the drug in powder. According to Viehoever, Keenan and Clevenger in the roots the endodermal cells of *V. viride* possess a U-shaped lumen whereas those of *V. album* possess a V-shaped lumen, further, the aerenchyma of *V. viride* shows air-spaces surrounded by disorganized parenchyma more pronounced than in *V. album.* These authors have found, during their investigation of *V. viride, V. album* and *V. californicum,* that the histological characters of the rhizomes and roots of these species vary to a considerable degree, showing a tendency to overlap in single instances. (*J. A. Ph. A.,* 1921, p. 581.) From a critical study of the published investigations thus far carried out on *V. viride* and *V. album,* we venture the opinion that no differences have been shown to exist between these two plants or their rhizomes or roots, which could not be explained on purely ecological grounds.

The pharmacognosy of *V. viride* has been well illustrated by Bastin (*A. J. P.,* 1895, p. 196). The structure of *V. album* has been presented by Meyer (*Arch. d. Pharm.,* 1882, p. 81; and in "*Wissenschaftliche Drogenkunde,*" vol. 2, p. 46). Rosenthaler has submitted veratrum to pyroanalysis and has obtained a sublimate which is in part crystalline and gives a yellowish-red color with sulphuric acid. (*Apoth. Zeit.,* xxviii, p. 991.)

Constituents.—The chemistry of *Veratrum viride* is rather confused, partly because of its complexity and partly because of the botanical similarities with the *V. album.* The latter has, in recent years at least, been more studied by chemists than the *V. viride,* but the physiological actions and the botanical relation of the two plants are so similar, that it is probable that they contain approximately the same alkaloids. The most abundant of the alkaloids is *jervine,* which is present in the proportion of from 0.1 to 0.3 per cent., but which H. C. Wood, Jr. (*J. A. M. A.,* 1906, xlvii, p. 2061), has shown to be physiologically relatively feeble. *Jervine,* $C_{26}H_{37}O_2N$, was first separated in a pure state by Wright and Luff (*Tr. Chem. Soc.,* 1878, xxxiii, p. 341) although the substance previously reported by Bullock under the name of *viridine* was probably an impure form of it. It crystallizes with 2 molecules of water and has a melting point of 241° C., according to Bredemann (*Ap. Ztg.,* 1906, xxi, p. 53). It has been reported in both species of veratrum (Pehkschen, *A. J. P.,* 1891). *Pseudojervine,* $C_{29}H_{43}O_7N$, and *rubijervine,* $C_{26}H_{43}O_2N$ (*veratroidine* of Bullock), which also occur in both species, are physiologically almost completely inert. The most active substance as yet isolated is *protoveratrine,* $C_{32}H_{51}O_{11}N$. It crystallizes in rectangular tablets with a melting point of 245° to 250° C. It was found by Salzberger (*A. Pharm.,* 1890, ccviii, p. 462) in the *V. album,* but has not yet been demonstrated in the *V. viride. Protoveratridine,* $C_{26}H_{45}O_8N$, has also been reported by Salzberger in the white hellebore; it is non-toxic. Traces of cevadine have been reported in *V. viride* and also of *Veradridine,* $C_{37}H_{53}O_{11}N$.

Assay.—The alkaloids of veratrum vary so greatly in their toxicity that a chemical assay is of very little use as an indication of the strength of the drug. At the same time there is evidence of considerable variation in the strength of different samples of the drug. Pilcher (*A. J. P.,* 1917, xliv, p. 1) reports variations of more than 100 per cent. between different preparations supposedly of the same strength. He has employed as test animals both guinea pigs and frogs. In the latter he found a very marked seasonal variation. In view of this fact and also that the toxic effects in man are upon the respiratory center, the guinea pig method would seem more serviceable. Pittenger has worked out details for the bio-assay of veratrum and suggests as a standard for the fluidextract an M. L. D., for the guinea-pig, of 0.05 Gm. per 250 Gm. body weight in 24 hours after hypodermic injection. He finds among samples tested a range of from 16 to 250 per cent. of standard. Rowe (*J. A. Ph. A.,* 1925, xiv, p. 24) prefers white mice as test objects. His standard is an M. L. D. of 0.25

milligramme per gramme body weight, which does not greatly differ from that of Pittenger.

Uses.—The various alkaloids present in veratrum act upon the system in very different manners, and none of them appears to exercise exactly the same action as the whole drug. According to H. C. Wood (*Phila. Medical Times,* 1874, iv, p. 737), jervine is a depressant to the respiratory center, to the vasomotor center, and to the heart muscle, and also lowers reflex activity by an effect upon the spinal cord, and rubijervine is chiefly a stimulant to the cardio-inhibitory mechanism, but has also a depressant action upon the respiratory center. According to Eden (*A. E. P. P.,* 1892, xxix, p. 440), small doses of protoveratrine stimulate cardiac inhibition thereby causing a lowering of the blood pressure. In large doses there is a secondary paralysis of inhibition accompanied by rise in the pressure. In large quantities it also exercises a poisonous effect upon the voluntary muscles similar to that of veratrine. Rubijervine is present in such small proportions (according to Breideman, *J. P.,* 1906, lxxxiv, 0.053 per cent.) and is so feeble a substance that it is improbable that it plays any part in the physiological action of the drug. Jervine although present in larger quantities (0.34 per cent.), according to H. C. Wood, Jr., is less poisonous than the drug itself. Protoveratrine, although present in small amounts (0.06 per cent., according to Breideman), is an extremely toxic substance and is the most important of the ingredients at present known. It appears to differ, however, in some of its properties from the whole drug.

When a moderate dose of veratrum is introduced into the system, the most marked change produced is reduction in the rate of the pulse accompanied with a fall in the arterial pressure. At the same time there may be some slowing in the respiration. With proper doses the slowing of the pulse is extreme and we have seen, in the lower animals, even complete arrest of the heart at this stage of the poisoning. The slowing of the pulse does not occur if the pneumogastric nerves have been divided previous to the injection of the drug, and is at once abolished either by section of these nerves or by the administration of atropine. It must be regarded, therefore, as due to stimulation of the cardio-inhibitory center. The reduction in the arterial tension in the normal animal may, therefore, be attributed to the slowing of the pulse. The conclusions of H. C. Wood, Jr. (*U. P. M. B.,* March, 1908), that contrary to the older views, veratrum does not lower arterial tone, have been confirmed by the experiments of Pilcher and Sollmann (*J. P. Ex. T.,* 1915, vii, p. 295) on animals, and by the observations of Collins (*A. I. M.,* 1915, xvi, pp. 54–58) on man. After toxic doses of veratrum there is a late paralysis of the intra-cardiac terminals of the pneumogastric nerve and consequent increase in the pulse rate with at first a rise of the blood pressure followed by a fall. This toxic fall in the blood pressure appears to be due to a direct depressant action upon the heart muscle. There is, following the toxic dose, also marked reduction in the respiratory activity, death being due eventually to failure of this function.

Veratrum was introduced into medicine about a century ago by the group of physicians who called themselves "eclectics." By them it was attributed with mysterious "adenagic" virtues and used in all sorts of inflammatory diseases. Later under the belief that it dilated the blood vessels and hence would relieve various local congestions, regular practitioners employed it largely in the treatment of *pneumonia, peritonitis,* and other sthenic *fevers.* While it is still employed to some extent in this type of disorder, our knowledge of its physiological action indicates that its true field of usefulness is rather in chronic, than in acute, diseases. Thus it is a very valuable agent for the reduction of excessively *high blood pressure* in *arteriosclerosis, interstitial nephritis,* and other conditions of hypertension; in cases with feeble myocardia it should be used cautiously because the stimulation of the cardio-inhibitory mechanism predisposes to cardiac dilatation. For the same purpose it is often employed in threatened *apoplexy,* in *chronic endocarditis,* especially in those in which there is considerable degree of cardiac hypertrophy, and in the so-called *irritable heart* seen in soldiers and athletes. In *exophthalmic goiter* and various other forms of *tachycardia* it is frequently of great service to reduce the pulse rate and prevent the heart exhausting itself in excessive activity. In certain of these conditions its line of usefulness more or less parallels that of digitalis. It differs, however, sharply from that drug, in that while digitalis tends to increase the tone of the heart muscle, veratrum rather diminishes cardiac tone. Veratrum has also been used widely by obstetricians in the treatment of *puerperal eclampsia.* Whether its benefit in this condition is to be attributed to a depressant action upon the motor cord, as some believe, or whether it be due to a lowering of the blood pressure, is as yet uncertain. The dose of veratrum must be gauged by the effect it produces; in general it may be said that if it does not slow the pulse no benefit will be received by the patient. The drug should therefore be pushed until evidence of its action is seen in the reduction of the pulse rate. Ordinarily from one to three minims (0.06–0.2 cc.) of the fluidextract may be given every two or three hours until it manifests its action. It should be remembered, however, that in some cases the cardio-inhibitory mechanism is refractory to the action of the drug and no dose will slow the pulse, and if given incautiously it may do great harm. Fortunately in most instances if given in too large dose it will manifest its toxic action by nausea before any more serious symptoms are produced.

Toxicology.—The symptoms of veratrum poisoning are vomiting accompanied with great nausea and much retching. There is profound prostration with muscular weakness, the skin bedewed with perspiration and pale in color, the pulse, in the milder cases, or in the early stage of the severe cases, is extremely slow and easily compressible, later, in the severe types of poisoning, it may become rapid and irregular. The respirations are often shallow and sometimes stertorous. Frequently there is much complaint of dizziness and in a few cases there has been dilatation of the pupil with disturbance of vision. Because of the promptness with which vomiting comes on even very large single doses of veratrum may be recovered from, thus Buckingham (*A. J. M. S.*, 1865) reports a case in which recovery followed a teaspoonful of the fluidextract. But when repeated large doses have been taken, the poisoning is much more dangerous.

In the treatment of veratrum poisoning if the patient be vomiting it is well to give a couple of glasses of water in order to thoroughly cleanse the stomach, at the same time twenty grains (1.3 Gm.) of tannic acid may be exhibited as an imperfect chemical antidote. If for any reason vomiting has not occurred it should be at once provoked or the stomach washed out by means of a stomach pump. The patient must be kept in a horizontal position and should not be allowed to sit up to vomit. After washing out the stomach in the manner described above, efforts should be made to stop the vomiting by the use of counter-irritation over the epigastrium and the cautious employment of morphine. But since when the drug proves fatal death is due to the respiratory arrest the latter should not be given in too large doses. If seen in the early stages when the pulse is slow, atropine is a remedy of great value antagonizing the effect of the veratrum upon the pneumogastric nerve and at the same time checking the excessive sweating and stimulating the respiratory center. Other active respiratory stimulants, such as hypodermic injections of ammonia and strychnine, may be employed, and if the bodily temperature is low it should be maintained by the external application of heat.

Dose, one to two grains (0.065–0.13 Gm.).

VERBASCI FLORES. N. F.

MULLEIN FLOWERS Verbasc. Flor.

"Mullein Flowers consist of the dried corollas, with adhering stamens, of *Verbascum phlomoides* Linné, or of *Verbascum thapsiforme* Schraeder (Fam. *Scrophulariaceæ*). Mullein Flowers contain not more than 2 per cent. of foreign organic matter. Flowers which have become brown should not be used." *N. F.*

Great Mullein; Mullein Dock; Flores Thapsi barbati; Bouillon Blanc (Fleurs de), Molène, *Fr.;* Flores Verbasci, *P. G.;* Wollkrautblumen, Koenigskersenblumen, *G.*

Off. Prep.—Species Pectorales, *N. F.*

VERBASCI FOLIA. N. F.

MULLEIN LEAVES [Verbasc. Fol.]

"Mullein Leaves are the dried leaves of *Verbascum Thapsus* Linné (Fam. *Scrophulariaceæ*). Mullein Leaves contain not more than 2 per cent. of foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

The mullein is a common weed native to Europe but abundantly naturalized in the United States, growing in open fields on stony hillsides. It is a tall, biennial herb reaching a height of 3 or 4 feet, terminating in a dense cylindrical spike of yellow flowers. The leaves are alternate and decurrent on the stem which is stout and simple. The whole plant is covered with a thick woolly pubescence. The corolla is rotate, almost regular and deeply five-lobed.

Folia Verbasci, *Fr. Cod.;* Feuilles de Bouillon Blanc, *Fr.;* Wollkrautblatter, *G.*

Description and Physical Properties.—The flowers are described as follows: "Corolla light yellow, the outer surface grayish with a fine, soft, woolly indumentum, the inner surface sparsely hairy and finely veined; tube of the corolla 1 or 2 mm. in length and almost equally broad, the limb from 14 to 30 mm. in width, between wheel-shaped and saucer-shaped, obscurely two-lipped, the unequal lobes rounded, obovate. Stamens five, borne on the base of the corolla, shorter than the corolla, two of them longer than the other three, the filaments thick and fleshy, more or less pilose, especially the three shorter ones, usually orange-colored. Stamen-hairs cylindrical, unicellular, non-branching, surface minutely reticulate, apex rounded, frequently enlarged. Pollen grains smooth, triangular and more or less rounded, from 0.025 to 0.035 mm. in diameter. Odor peculiar, agreeable; taste mucilaginous, not agreeable.

"The flowers impart a yellow color to boiling water, and a rather permanent green color with dilute sulphuric acid, the latter color becoming brown upon the addition of alkalies." *N. F.*

The N. F. gives the following description of the leaves.

"*Unground Mullein Leaves.*—Obovate with narrowed base, or varying to oblong or oblong-lanceolate, without a true petiole, obtuse or tending toward acuteness at the summit, from 1 to 6 dm. in length and from 3 to 15 cm. in width; very thick, rather tough when damp, brittle when dry, light yellowish gray or greenish gray, densely long-tomentose, with numerous, multicellular, branching, non-glandular hairs. Nearly odorless; taste mucilaginous and slightly bitter.

"*Powdered Mullein Leaves.*—Dark green; numerous branching multicellular slightly lignified hairs consisting of an upright, jointed central stalk with whorls of from 2 to 8 radiating lateral cells arising at the joints or apex, the lateral cells measuring up to 0.600 mm. in length; glandular hairs with a 1-celled stalk and a unicellular head, the latter from 0.020 to 0.030

mm. in diameter; numerous fragments consisting of epidermal cells with broadly elliptical stomata, the latter from 0.020 to 0.030 mm. in length and chlorenchyma associated with fibrovascular tissue." *N. F.*

According to Kobert (*Ph. Wb.*, 1918, lv, p. 49), the *V. Thapsus* contains several saponins. According to L. Rosenthal (*P. J.*, July, 1902), the seeds of *Verbascum sinuatum* L., which are used in Greece as a fish poison, contain 6.13 per cent. of a saponin. Traces of the same substance were found in the fruits of *V. phlomoides* L. and *V. thapsiforme* Schrad.

Uses.—Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild *catarrhs.* An oil, produced by saturating olive oil with mullein flowers, during prolonged exposure to the sun, is used as a local application in Germany for *piles* and other *mucous membrane inflammations.* The mullein oils sold in pharmacies are of this nature, or some of them alcoholic tinctures. The dried leaves are sometimes smoked to relieve irritation of the respiratory mucous membranes; fomentations with mullein leaves also have some repute as anodynes. Internally, the decoction (an ounce to the pint, flowering tips) may be taken in the quantity of from four to six fluidounces.

Dose, from one to two drachms (4–8 Gm.).

Off. Prep.—Fluidextractum Verbasci Foliorum, *N. F.*

VIBURNUM OPULUS. N. F.

VIBURNUM OPULUS Viburn. Op.
[High Bush Cranberry Bark, Cramp Bark]

"Viburnum Opulus is the dried bark of *Viburnum Opulus* Linné var. *americanum* (Miller) Aiton (Fam. *Caprifoliaceæ*). Viburnum Opulus contains not more than 5 per cent. of adhering wood or other foreign organic matter." *N. F.*

High Bush Cranberry; Cramp-Bark; Wild Guelder Rose; Rose Elder; Squaw Bush; Pincushion Tree; Cherry-wood; Obier, *Fr.;* Wasserholderinde, Wasserschwelke, *G.*

Viburnum Opulus L. var *americanum* Ait. (*V. americanum* Mill.), *cranberry bush* or *high bush cranberry,* belongs to the section of the genus which has peduncled cymes, light red, acid, roundish drupes, with very flat orbicular not sulcate stones, palmately veined leaves, and scaly winter buds. It is a large bush, reaching the height of ten feet, growing in low grounds from New Brunswick far westward, and southward to Pennsylvania. The leaves are from three- to five-ribbed, strongly three-lobed, broadly wedge-shaped or truncate at the base, with the spreading pointed lobes mostly toothed in the sides and entire in the sinuses. The petioles bear two glands at the apex. The *snow-ball tree,* or *Guelder rose,* represents the var. *sterile* DC. in which the whole inflorescence has been turned into a mass of showy sterile flowers.

Description and Physical Properties.—"*Unground Viburnum Opulus.*—In strips, or occasionally in quills or chip-like fragments, the bark attaining a thickness of 3 mm.; outer surface of the thinner pieces of a light gray color with crooked, longitudinal, purplish brown stripes and very small brown lenticels, the thicker pieces purplish red or occasionally blackish, except when very young, and more or less finely fissured or thinly scaly; inner surface varying in color from yellowish to rusty-brown, with very short oblique striæ, except where the outer wood layer adheres; fracture short and weak, the fractured surface mostly whitish, varying to pale brown in the inner layer, rusty brown in the outer layer, covering the green tangential layer of phelloderm. Odor slight and characteristic; taste mildly astringent and decidedly bitter.

"*Structure.*—An outer corky layer of 5 to 25 rows of cells, the walls being nearly colorless, frequently thickened on the inner surface, individual cork cells from 0.015 to 0.045 mm. in radial diameter and from 0.030 to 0.075 mm. in tangential diameter; middle bark of about 10 rows of cells containing a brownish yellow, amorphous substance, small starch grains or chloroplastids; medullary rays one to two cells in width, usually not more than one-cell wide; inner bark with occasional groups of bast fibers composed of 1 to 10 cells, the walls being very thick, non-lignified, lamellated and finely porous; adhering wood with large tracheæ having scalariform or reticulate thickenings, and being surrounded by wood fibers with thick lignified walls.

"*Powdered Viburnum Opulus.*—Light grayish brown, consisting of irregular fragments; polygonal cork cells, with thin, colorless walls; parenchyma with rosettes of calcium oxalate, from 0.010 to 0.040 mm. in diameter; starch grains mostly in parenchyma cells and up to 0.010 mm. in diameter; fragments of parenchyma containing a brownish yellow amorphous substance; occasional tracheal fragments associated with lignified wood fibers, bast fibers and stone-cells." *N. F.*

The bark described in the U. S. P. VIII as "Viburnum Opulus" was that of *Acer spicatum* Lam., commonly known as *mountain maple,* or *false cramp-bark* as shown first by Satter and Farwell. Farwell states that as early as the nineties, *A. spicatum* was mistaken for *true cramp-bark* (*V. Opulus*) and that from then on until 1913, this bark represented the commercial cramp-bark. He gives detailed distinctions between mountain maple and true cramp-bark in an elaborately illustrated article (*Bull. of Pharm.*, 1913, 65). Viehoever, Ewing and Clevenger, in 1918, again called attention to the extent of the substitution of *A. spicatum* for *Viburnum Opulus.* They state that the barks as well as the preparations can be distinguished by the different color reactions of the tannins in the barks with iron salt, these being blue in *A. spicatum* and green in *Viburnum* (*J. A. Ph. A.*, 1918, p. 944). Despite the ruling of the U. S. Dept. of Agric. that all material labelled "cramp-bark" must represent the bark of *V. Opulus* var. *americanum,* substitution still continues, probably due to the synonym "cramp-bark" being commonly used for *A. spicatum* in the southern Appalachians, where much of this substitute drug is collected. The bark of *Acer spicatum* may readily be distinguished from that of *Viburnum Opulus* var. *americanum* by its fibrous fracture, absence of a valeric acid odor, especially when triturated in a mortar with phosphoric acid, and by its inner structure which exhibits numerous lignified, sclerenchyma fibers in cortex, pericycle and phloem as well as scattered monoclinic prisms of calcium oxalate. The bark of an *elder* has recently been reported as being used to adulterate cramp-bark (*Proc. N. W. D. A.*, 1921, 215).

For studies of Viburnum barks, see *A. J. P.*, 1895, 378, 394; also *Ph. Post.*, 35, 773.

Heyl (*J. A. Ph. A.*, 1922, xi, 329) found in the resinous extract a number of fatty acids, including acetic, caproic, valeric, palmitic, etc., and traces of a paraffin, myricyl alcohol and two phytosterols; in the water soluble extract he found acetic and valeric acids, tannin and sugar. There was also indications of a small amount of glucoside but no alkaloid.

It contains valeric acid, an enzyme, and viburnin (see *Viburnum prunifolium*).

Uses.—The berries of this plant are used to a considerable extent as a substitute for the ordinary cranberry, and are antiscorbutic, but there is no sufficient reason to believe the bark has any medicinal properties of any kind. It is occasionally employed with other drugs in functional uterine disorders but Pilcher and Burman (*J. A. M. A.*, 1916, lxvii, 490) has shown that it has no effect on the uterus. *V. obovatum* Walt., a tree shrub growing from Virginia southward, is said to be an antiperiodic. (*A. J. P.*, 1878.)

Dose, thirty to sixty grains (2–4 Gm.).

Off. Prep.—Elixir Viburni Opuli Compositum, *N. F.;* Fluidextractum Viburni Opuli, *N. F.;* Tinctura Viburni Opuli Composita, *N. F.;* Elixir Aletridis Compositum, *N. F.;* Elixir Heloniadis Compositum, *N. F.*

VIBURNUM PRUNIFOLIUM. N. F. (Br.)

VIBURNUM PRUNIFOLIUM Viburn. Prun.
[Black Haw, Viburnum]

"Viburnum Prunifolium is the dried root bark of *Viburnum prunifolium* Linné (Fam. *Caprifoliaceæ*). Viburnum Prunifolium contains not more than 7 per cent. of wood or other foreign organic matter and yields not more than 3 per cent. of acid-insoluble ash." *N. F.*

"Black Haw is the dried bark of Viburnum prunifolium, *Linn.*" *Br.*

Viburnum, *Br.;* Black Haw; Stagbush; Sheep-berry; Sloe; Viburno (Corteza de), *Sp.*

Viburnum prunifolium is a very handsome shrub or small tree which is quite common in the Middle and Southern United States, east of the Mississippi, flowering in May and ripening in the early autumn its ovoid or oblong blackish fruit. It is specifically characterized by its short pointed winter buds, by its acuminate, sharply serrulate, ovate leaves on long, slender glabrous, often narrow margined petioles. Its sessile, white flowered cymes are 2 to 5 inches broad and bear oval bluish-black drupes slightly over one-third inch in length.

Viburnum Lentago L., *Sheep Berry,* or *Nanny Berry,* resembles the previous species, but has the winter buds longer pointed, and its leaves stouter petioled with a distinctly wavy margined petiole. Its geographical limit overlaps that of *V. prunifolium,* but extends much further westward and northward, even to Hudson Bay and Manitoba. The bark of *V. dentatum* L., or *Arrow wood,* is said to be sometimes substituted for the official drug. Most of the commercial supply of *V. prunifolium* is obtained from western North Carolina.

Description and Physical Properties.—"*Unground Viburnum Prunifolium.*—In irregular, transversely curved or quilled pieces, from 1.5 to 6 cm. in length, and from 0.5 to 1.5 mm. in thickness; outer surface grayish brown, or, where the outer cork has scaled off, brownish red, longitudinally wrinkled; inner surface reddish brown, longitudinally striated; fracture short but uneven, showing in bark which is young or of medium thickness, a dark brown cork, a brownish red outer cortex, and a whitish inner bark in which are numerous light yellow groups of cells. Odor strong, sourish; taste distinctly bitter and somewhat astringent.

"*Structure.*—Outer bark of variable thickness composed of somewhat lignified cork cells, many of the latter with a brownish amorphous content; middle bark chiefly composed of tangentially elongated cortical parenchyma; inner bark with nearly straight medullary rays up to 2 cells in width and separated by sieve and parenchyma tissue; middle and inner bark with numerous groups of stone cells and characteristic rifts between the parenchyma; parenchyma cells containing either oil globules, brownish amorphous masses, starch grains, or calcium oxalate occasionally in monoclinic prisms, usually in rosette-aggregates, the latter often occurring in the inner bark in rows of cells.

"*Powdered Viburnum Prunifolium.*—Dark brown; numerous rounded or elongated stone cells, from 0.040 to 0.150 mm. in length, with thick, porous, lignified walls; calcium oxalate in rosette-aggregates or occasionally monoclinic prisms from 0.010 to 0.040 mm. in diameter; numerous fragments of lignified cork tissue;

fragments composed of parenchyma cells containing simple starch grains from 0.003 to 0.015 mm. in diameter; bast fibers few." *N. F.*

"In quills or curved pieces, one to four millimetres thick; dull brown or reddish-brown. Outer surface longitudinally wrinkled or, in older bark, with shallow fissures and scaly; inner surface longitudinally striated, reddish-brown. Fracture granular. In transverse section, a dark brown outer portion and a whitish or reddish bast with numerous groups of sclerenchymatous cells. Slight odor; taste astringent and bitter." *Br.*

The morphology of *Viburnum prunifolium* is well illustrated by Holm in *M. R.*, xxii, p. 35. Illustrations of the bark of the several species of viburnum are given in Kraemer's "*Scientific and Applied Pharmacognosy*"; also see *P. J.*, 1903, lxx, p. 197. Lloyd states that the bark of all native species of viburnum are collected by root diggers and sold under the name of black haw. (*Ph. Rev.*, xxiii, p. 333.) The bark of the root is preferred to that of the stem and the official definition formerly limited the drug to the root bark. Farwell reported the substitution of the genuine drug by the bark of some other species of viburnum than those specified by the Pharmacopœia. The bark is much darker than the official bark and consisted largely of stem bark. (*M. R.*, xvii, p. 35.) Youngken has reported a recent substitute which is collected in western North Carolina as "Shonny Haw bark" and which is stated by McManus to be collected from *V. nudum* L.

Herman van Allen found the following constituents in viburnum: (1) a brown resinous body, of a very bitter taste, from which it was found impossible to separate the sugar; (2) a greenish-yellow resin, or neutral principle, of a bitter taste, slightly soluble in water, freely so in alcohol, called by Krämer *viburnin;* (3) valeric acid; (4) a tannic acid giving a greenish-black color with ferric salts; (5) oxalic acid; (6) citric acid; (7) malic acid; (8) sulphates; (9) calcium, magnesium, potassium, and iron chlorides. (*A. J. P.*, 1880, 443.) As the result of elaborate investigation, T. Shennan (*Royal Coll. Phys. Lab. Rep.*, Edinburgh, vi, 1897) concludes that the *Viburnum prunifolium* contains *viburnic—i.e.*, valeric—acid, and a non-volatile alkaloid which, however, he failed to obtain in a pure condition. For examination of this bark by Heyl and Barkenbus see *J. Am. Chem. Soc.*, 1920, xlii, 1744.

Uses.—Viburnum has been used quite largely in the treatment of *dysmenorrhea, after-pains,* and other uterine disorders. Pilcher (*A. I. M.*, Jan., 1917), however, has shown that in the doses ordinarily employed it has no effect of any kind on the uterine muscle. Hager and Becht (*J. P. Ex. T.*, 1919, xiii, 61) have reached similar conclusions.

R. L. Payne, Jr., has found that when given in toxic amount to the lower animals viburnum produces muscular weakness, ending in complete paralysis with loss of reflex action, which he believes to be due to an influence upon the motor side of the spinal cord. In warm blooded animals there is also marked lowering of the arterial pressure, believed by Payne to be the result of a direct action of the drug upon the heart. Experiments of Payne have in a measure been confirmed by those of T. Shennan, but as the latter took six drachms of the fluidextract within thirty minutes, with no demonstrable effect except a doubtful decrease of the rate and force of the pulse, it is plain that the drug is very feeble.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Fluidextractum Viburni Prunifolii, *N. F.* (*Br.*); Elixir Viburni Prunifolii, *N. F.*

VINA MEDICATA

MEDICATED WINES

Vins médicinaux, Œnolés, *Fr.;* Medicinische Weine, *G.*

All wines were deleted from the U. S. P. IX. The Br. Pharm. 1914 retains sherry wine as a menstruum, and also an "Orange Wine" (see *Vinum Aurantii*).

The reported advantages of wine as a pharmaceutical menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change, while at the same time it is less stimulating than strong or diluted alcohol, owing to its smaller proportion of alcohol. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition, and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant, and the preparations, therefore, made with them lacked uniformity. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, from wine of proper identity and strength, and should be kept in a cool place. *Detannated wine* may be best made by digesting the wine with casein which has the advantages of milk, formerly used, without its diluting effect or the introduction of foreign and undesirable constituents. Gelatin has also been used successfully for the same purpose, but is somewhat inferior to casein, which is now obtainable either in the soluble or insoluble form. The former should be used and the latter form may be made soluble by the careful use of an alkali. Ferric hydroxide should never be used for detannating wines, for, while it successfully removes the tannin, it also removes other valuable constituents and the acid of the wine always takes up a little of the iron so that a slightly ferruginous preparation results, which is usually undesirable.

VINUM ANTIMONIALE. Br.

ANTIMONIAL WINE

Wine of Antimony; Vin antimonié, Vin émétique, Vin stibié, *Fr.;* Vinum Stibiatum, *P. G.;* Brechwein, *G.;* Vino emetico, *Sp.*

" Tartarated Antimony, 4 *grammes;* Distilled Water, boiling, 40 *millilitres;* Sherry, sufficient to produce 1000 *millilitres.* Dissolve the Tartarated Antimony in the Distilled Water, and add sufficient Sherry to produce the required volume." *Br.*

Considerable difficulty is often experienced in effecting a solution of tartar emetic in wine, and precipitation is likely to occur after the solution has been effected. These results are undoubtedly due to the variability in the amount of tannic acid in wines of different type and quality. Paris stated that he had seen the decomposition of the tartar emetic so complete that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan adopted in the Br. of first dissolving the antimonial in water and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and wine which is low in tannic acid content, to make a permanent solution.

The advantages of antimonial wine are that it affords the means of administering minute doses of tartar emetic, and that it is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is used only as a diaphoretic or expectorant.

Dose, from ten to thirty minims (0.6–1.8 cc.).

VINUM AURANTII. Br.

ORANGE WINE

Vin d'Ecorce d'orange amère, *Fr.;* Pomeranzenwein, *G.;* Vino de Corteza Naranja amarga, *Sp.*

" Orange Wine is made by the fermentation of a saccharine solution to which Fresh Bitter-Orange Peel has been added." *Br.*

This is officially described as " a vinous liquid, having a golden sherry color, and a taste and aroma derived from the Bitter-Orange Peel. Contains from 12 to 14 per cent. by volume of ethyl hydroxide. Not more than slightly acid to *litmus.* When 50 millilitres are made alkaline with *solution of sodium hydroxide,* evaporated to a small bulk, acidified with *hydrochloric acid,* and shaken with *benzene,* the residue obtained on evaporating the benzene solution, when dissolved in *water,* does not assume a violet color on the addition of a drop of *T. Sol. of ferric chloride* (absence of salicylic acid). Yields not more than the slightest characteristic *reactions* for sulphites." *Br.*

This wine is used as a vehicle, and is the official menstruum for several Br. preparations.

VINUM COLCHICI. Br.

COLCHICUM WINE

Vinum Colchici Cormi, *N. F. IV;* Wine of Colchicum corm; Vinum Colchici Radicis, *U. S.* 1890; Wine of Colchicum Root; Vin de Bulbe de Colchique, *Fr.;* Zeitlosenknollenwein, *G.;* Vino con colchico, *It.*

" Colchicum Corm, in No. 20 powder, 200 *grammes;* Sherry, 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

In *gout* this wine is frequently given in connection with magnesium sulphate. It is a violent poison in overdoses. Two fluidrachms and a half (9.3 cc.) of it are said to have caused death.

Dose, ten to forty minims (0.6–2.5 cc.).

VINUM FERRI. Br.

IRON WINE

Vinum Chalybeatum, s. Martiatum; Eisenwein, Stahlwein, *G.*

" Iron, in wire, 50 *grammes;* Sherry, 1000 *millilitres.* In a closed vessel partially immerse the Iron in the Sherry; continue the maceration until the filtered liquid responds to the following test:—Evaporate 50 millilitres to dryness, incinerate the residue, heat the ash with *hydrochloric acid* diluted with an equal volume of *water,* filter, wash the filter paper with *water,* and add to the mixed filtrate and washings excess of *solution of ammonia.* Collect the precipitate, wash, dry and ignite; the residue weighs not less than 0.089 or more than 0.215 gramme, representing a proportion of not less than 0.125 or more than 0.300 gramme of iron, calculated as iron, Fe, in 100 millilitres of the Wine." *Br.*

(See also *Vinum Ferri Citratis.*)

When wine is made to react on metallic iron with presence of air, the metal is oxidized, and then unites with the excess of acid of the potassium bitartrate, which is the characteristic salt of wines. The ferruginous salt, therefore, formed is iron and potassium tartrate, or the tartarated iron of the Br. Pharmacopœia, and this was the old method of preparing the Wine of Iron. But it is obvious that the strength in iron cannot be entirely uniform, as the quantity dissolved must depend on the proportion of the bitartrate in the wine, which is variable, and on various circumstances of the manipulation. In consideration of these objections, it was thought best, in the Br. formula of 1864, to substitute a simple solution in the wine, of the iron and potassium tartrate already formed, and to abandon the old tedious formula. But it is obvious that a solution of the ferruginous salt in wine is not exactly the same as the wine of iron prepared with the metal, as it contains the potassium bitartrate unaltered. For this and other reasons, the Br. Pharmacopœia has returned to the old method.

Dose, one to four fluidrachms (3.75–15.0 cc.).

VINUM FERRI CITRATIS. Br.

WINE OF IRON CITRATE

Vinum Ferri, *N. F. IV;* Wine of Iron; Vinum Chalybeatum, Wine of Ferric Citrate; Vin Chalybé, Œnolé ferrugineux, Vin ferrugineux, *Fr.;* Eisenwein, *G.;* Vino de Citrato Ferricoamonico, *Sp.*

"Iron and Ammonium Citrate, 18 *grammes;* Orange Wine, sufficient to produce 1000 *millilitres.* Dissolve. Shake occasionally for three days; filter." *Br.*

Dose, one to four fluidrachms (3.75–15.0 cc.).

VINUM IPECACUANHÆ. Br.

IPECACUANHA WINE

Wine of Ipecac; Vin d'Ipécacuanha, *Fr.;* Brechwurzelwein, *G.*

"Liquid Extract of Ipecacuanha, 50 *millilitres;* Sherry, 950 *millilitres.* Mix; set aside for forty-eight hours; filter." *Br.*

This wine is much weaker than that formerly recognized by the N. F. IV.

Wine of ipecac possesses all the medicinal properties of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. It is much used as an expectorant and a diaphoretic, and the effects of the Dover's powder may be obtained by combining it with a liquid preparation of opium.

Dose, expectorant, ten to thirty minims (0.6–2 cc.); emetic, four to six fluidrachms (16–20 cc.).

VINUM QUININÆ. Br.

QUININE WINE

Vin de Quinine, *Fr.;* Chininwein, *G.;* Vino de Quina, *Sp.*

"Quinine Hydrochloride, 2 *grammes;* Orange Wine, 875 *millilitres.* Dissolve; filter if necessary." *Br.*

The Br. Ph., 1898, replaced quinine sulphate used in the 1885 process by quinine hydrochloride on account of the greater solubility of the latter. Each fluidounce contains one grain of quinine hydrochloride.

Dose, one-half to one fluidounce (15–30 cc.).

VINUM XERICUM. Br.

SHERRY WINE Vin. Xeric.

"Sherry is a Spanish wine." *Br.*

Sherry wine is not official in either the U. S. P. or N. F.

"Pale yellowish-brown, containing not less than 16 per cent. by volume of ethyl hydroxide. Contains in 100 millilitres not less than 0.1 or more than 0.2 gramme of volatile acids, calculated as acetic acid, $HC_2H_3O_2$, and not less than 0.3 or more than 0.45 gramme of fixed acids, calculated as tartaric acid, $H_2C_4H_4O_6$, when tested by the following process:—(1) Titrate 25 millilitres of the Sherry with *N/5 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator, and note the number (*a*) of millilitres of the former solution required. (2) Introduce 25 millilitres of the Sherry with 25 millilitres of *water* into a flask capable of holding 200 millilitres and attach a condenser; add 0.5 gramme of *tannic acid,* and distil gently until about 25 millilitres have been collected. Then pass a current of steam through the residual liquid in the flask, and continue the distillation until about 200 millilitres in all have been collected. Titrate the distillate with *N/5 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. The number (*b*) of millilitres of the former solution required is not less than 2.1 or more than 4.2, representing a proportion of not less than 0.1 or more than 0.2 gramme of volatile acids, calculated as acetic acid, $HC_2H_3O_2$, in 100 millilitres of the Sherry. Deduct the number (*b*) of millilitres required in (2) from the number (*a*) of millilitres required in (1). The difference is not less than 5 or more than 7.5, representing a proportion of not less than 0.3 or more than 0.45 gramme of fixed acids, calculated as tartaric acid, $H_2C_4H_4O_6$, in 100 millilitres of the Sherry. When 50 millilitres of the Sherry are made alkaline with *solution of sodium hydroxide,* evaporated to a small bulk, acidified with *hydrochloric acid* and shaken with *benzene,* the residue obtained on evaporating the benzene solution, when dissolved in *water,* does not assume a violet color on the addition of a drop of *T. Sol. of ferric chloride* (absence of salicylic acid)." *Br.*

XANTHOXYLI FRUCTUS. N. F.

PRICKLY ASH BERRY Xanthox. Fruct.

"Prickly Ash Berry is the dried fully grown fruit of *Xanthoxylum americanum* Miller (Northern Prickly Ash) or *Xanthoxylum Clava-Herculis* Linné (Southern Prickly Ash) (Fam. *Rutaceæ*). Prickly Ash Berry contains not more than 2 per cent. of foreign organic matter." *N. F.*

For information concerning these shrubs see next article.

Description and Physical Properties.—The berries are officially described as follows: "*Unground Prickly Ash Berry.*—Capsules with short stalks (*X. Americanum*) or without stalk (*X. Clava-Herculis*); ellipsoidal, fleshy, gray-brown, dehiscent; carpels two, convex, apex short pointed; seed one or two, oblong black, shining and wrinkled from drying. Taste pungent, warm, aromatic and on chewing leave a tingling sensation on the tongue; odor when breathing upon, faintly aromatic resembling that of citral.

"*Powdered Prickly Ash Berry.*—Dark brown; numerous fragments of pericarp tissue showing large oil cavities and vascular tissue surrounded by parenchyma cells, the latter containing irregular masses or sphaerocrystals of hesperidin; fragments of the inner layer of pericarp composed of narrow, irregular, elongated cells with thick lignified walls and simple pores; polygonal cells of the seed coat with dark brownish walls; numerous globules of volatile oil." *N. F.*

Xanthoxylum berries do not appear to contain any active substance other than a volatile oil. They probably have no therapeutic effect except that of a mild aromatic.

Dose, as given in the N. F., fifteen grains (1 Gm.).

Off. Prep.—Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

XANTHOXYLUM. N. F.

XANTHOXYLUM Xanthox. [Prickly Ash Bark]

"Xanthoxylum is the dried bark of *Xanthoxylum americanum* Miller, known in commerce as Northern Prickly Ash Bark, or *Xanthoxylum Clava-Herculis* Linné, known in commerce as Southern Prickly Ash Bark (Fam. *Rutaceæ*). Xanthoxylum contains not more than 2 per cent. of foreign organic matter." *N. F.*

X. amercianum; Toothache Tree, Angelica Tree, Suterberry, Pellitory Bark, Yellow-wood; Clavalier, Frêne épineux, *Fr.;* Zahnwehholz, Zahnwehrinde, *G.*
X. Clava-Herculis; Sea Ash, Hercules' Club, Pepper-wood.

The *Xanthoxylum* (or more properly *Zanthoxylum*) *Americanum* Miller (X. *fraxineum* Willd.) or *Northern Prickly Ash* is a shrub from five to twenty-five feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile clustered cymes near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the carpels three or four in the perfect flowers, about five in the pistillate. The capsules are stipitate, oval, punctate, of a greenish-red color, with two valves, each with one oval blackish seed. It grows in woods and in moist shady places from Quebec to Georgia, Mississippi and Nebraska. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odor, recalling that of oil of lemon.

Botanists are not agreed concerning the distinction of the genus *Fagara* from *Zanthoxylum.* The most important character separating them seems to be the absence of sepals in *Zanthoxylum.* Most of the species of the genus *Fagara* are tropical trees.

Z. Clava-Herculis L. [*Fagara Clava-Herculis* (L.) Small, *Z. carolinianum* Lam.], or *Southern Prickly Ash,* is a small tree. Its bark is armed with warty prickles, and large conical cork wings occur on the branches and the petioles. The alternate leaves have from seven to eleven ovate-lanceolate, crenate-serrulate, unequal-sided leaflets, smooth and shining on the upper surface. It grows on dry soil, westward as far as western Texas, and perhaps into Mexico, eastward to the Atlantic coast, and northward to southern Virginia, especially affecting the coast region.

The fruits (*Prickly ash berries*) of both of the official species probably contain the same principles found in the barks. The dried berries are recognized by the N. F. V under the name of *Xanthoxyli Fructus,* and are described below.

There has been much confusion in regard to the nomenclature of the prickly ashes. *Aralia spinosa* L., or angelica tree, which grows in the Southern States, is occasionally confounded with *Z. Clava-Herculis,* in consequence partly of being sometimes called, like the latter, *prickly ash.* Its bark is nearly smooth externally, is beset with slender prickles in transverse rows and has a taste different from that of *F. Clava-Herculis.* Besides the official trees, the bark of *F. flava* (Vahl) Frug. and Urban (*Z. caribæum* S. Wats.), the *satin-wood* of semi-tropical Florida and the West Indies, has appeared in commerce under the name of *yellow Hercules' club* or *yellow thorn.* This bark is thin, with an odor like that of Angustura bark, a bitter, disagreeable, acrid taste, and a canary-yellow color, which it imparts to the saliva when chewed. It would seem, also, that under the name of *prickly yellow wood, yellow wood,* or *fustic,* the products of other West Indian xanthoxylums and allied plants find their way into commerce.

Zanthoxylum veneficum Bailey, of Australia, is, according to J. H. Maiden, a violent convulsive poison, 5 grains of the extract being a fatal dose for a cat. *Zanthoxylum scandens* is said to be used by the natives of Java as a fish poison, and according to Van der Haar, contains an alkaloid. (*P. J.,* 1902, lxxi, 134; lxxiii, 814.)

The N. F. gives the following description of the bark:

"*Unground Northern Xanthoxylum.*—In transversely curved fragments or quills from 2 to 15 cm. in length; bark from 0.5 to 2 mm. in thickness; outer surface light gray to brownish gray with grayish patches of foliaceous lichens; longitudinally wrinkled and with numerous whitish lenticels; the cork occasionally abraded, showing the yellowish or orange, inner bark; inner surface yellowish white, finely longitudinally striate and usually with numerous, bright, shining crystals; fracture short, uneven. Odor slight; taste bitter, acrid, becoming pungent.

"*Structure.*—An outer corky layer consisting of from 4 to 20 rows of cells, the tangential walls being more or less thickened and lignified; a wide stratum of collenchyma inside of the cork cambium composed of from 8 to 10 rows of tangentially elongated cells, with very thick walls and containing plastids; a more or less indistinct row of endodermal cells beneath which occur small groups of primary bast-fibers; the inner bark consists of numerous parenchyma cells among which are included large oil-secretion reservoirs, and occasionally a few stone cells, separated by medullary rays which are mostly one cell in width; the parenchyma cells as well as the oil-secretion reservoirs contain numerous colorless oily globules. Scrapings from either the inner or outer surface show numerous rod-shaped crystals and flat prisms, from 0.015 to 0.250 mm. in length, which polarize light with a display of bright colors.

"*Unground Southern Xanthoxylum.*—In transversely curved or irregular, oblong, flattened pieces, or in quills from 2 to 40 cm. in length, bark from 1 to 4 mm. in thickness; outer surface light gray to brownish gray, marked by numerous large barnacle-shaped projections of cork, from 0.5 to 3.5 cm. in thickness and numerous elliptical lenticels; otherwise with grayish patches of foliaceous lichens; inner surface light yellowish brown to olive-brown, obscurely longitudinally striate and free from crystals. Odor and taste as in Northern Prickly Ash Bark.

"*Structure.*—A strong development of lignified cork in successive layers, the layers being separated by several rows of narrow tabular cells strongly thickened on the tangential walls; beneath the cork cambium occurs a thin layer of collenchyma followed by the outer tissues of the primary cortex and consisting of small groups of rather large stone cells and occasional, scattered groups of bast-fibers and parenchyma; the inner bark consists of parenchyma, a more or less indistinct sieve tissue among which are numerous, large, light yellowish oil-secretion reservoirs, medullary rays 1 or 2 cells in width and occasional groups of stone cells and bast-fibers; starch grains numerous, occurring in the parenchyma cells and medullary rays; calcium oxalate chiefly in monoclinic prisms occurring in crystal fibers and in parenchyma cells of the primary cortex.

"*Powdered Xanthoxylum.*—Light grayish brown, irregular fragments of cork cells, nearly colorless and strongly lignified, fragments of parenchyma containing eight small nearly spherical starch grains 0.002 to 0.010 mm. in diameter, oily globules or monoclinic prisms of calcium oxalate the latter 0.010 to 0.045 mm. in length; stone cells up to 0.150 mm. in length in small groups, with thick, colorless walls and frequently containing a reddish brown substance; bast fibers few and non-lignified. In the Northern Prickly Ash, the stone cells and the fragments of cork are relatively few." *N. F.*

Southern Prickly Ash has been adulterated with the bark of *Aralia spinosa* which can be readily detected by the sharp spines which are closely set and not mounted on corky cones. The bark of a tropical American species, X. *Ochroxylum* DC., has been the subject of a pharmacognostical study by Leprince. (*Repert. Pharm.*, 1912, xxiv, p. 215.)

W. L. Cliffe after careful examination demonstrated that the bark of Southern prickly ash exceeded that of the Northern prickly ash in active properties. (*A. J. P.*, 1901, 562.)

Constituents.—The Xanthoxylum barks contain berberine and probably one or more other alkaloids, which may be derivatives of berberine. There is some doubt whether the alkaloids of the two species are identical.

In 1826 Chevalier and Pellatan found in the Southern prickly ash (X. *Clava-Herculis*) a yellow alkaloidal substance which they called *xanthopicrit;* subsequently Perrins (*J. Chem. Soc.*, 1862, xv, 339) showed this to be berberine. G. H. Colton (*A. J. P.*, 1880, p. 191) separated from the Southern prickly ash, tastless, colorless, silky acicular crystals, soluble in alcohol, ether, and chloroform, less soluble in benzene, and insoluble in water.

The first to report an alkaloid in the bark of the *x. americanum* (Northern prickly ash) was Edward Staples who in 1829 isolated a colorless crystalline substance which he named *xanthoxyline.* This finding was confirmed by J. V. Lloyd in 1876. Subsequently, from the same plant Edward T. Moffet (*A. J. P.*, 1886, 417) obtained a supposed alkaloid in yellow crystals, soluble in alcohol and chloroform, insoluble in petroleum benzin, ether, and benzene. This was probably berberine.

The identity of the alkaloids from the two species was generally assumed until the analysis of Eberhardt. (*A. J. P.*, 1890, 231.) He obtained from the Southern prickly ash a colorless crystalline principle agreeing in solubilities with that of Colton. On analysis it gave figures indicating the formula $C_{20}H_{19}O_6$ or $C_{30}H_{28}O_9$. At the same time he analyzed a sample of Lloyd's crystalline principle from X. *americanum*, which had been preserved in the museum of the Philadelphia College of Pharmacy, and found for it the formula $C_{29}H_{27}O_8$. Numerous reactions also indicated that the two principles were different. Thus, Lloyd's crystals (xanthoxyline) dissolve in concentrated sulphuric acid with light red color, and on the addition of an excess of water produce a whitish precipitate which is taken up by chloroform; the crystals from the X. *Clava-Herculis* dissolve in concentrated sulphuric acid with dark red color, and on dilution separate a purplish precipitate, which is not taken up by chloroform. Lloyd's principle melts, moreover, at 129.5° C., while Eberhardt's melts at 110° C.

X. senegalense (*artar root*) was analyzed by Giacosa and Soave (*A. J. P.*, 1890, 500), who found a fixed oil, a neutral crystalline substance, melting at 120° C., and two alkaloids. The first of these they call *artarine,* and give to it the formula $C_{20}H_{17}O_4N$ (which makes it agree with *berberine*), or $C_{21}H_{23}O_4N$, in which case they consider that it may be *methylhydroberberine.* The second alkaloid, crystallizing in blood-red needles, they did not analyze. In X. *Ochroxylum,* Leprince (*B. Sc. Pharm.*, 1912, xviii, 337) found an alkaloid, *xantherine,* allied to berberine. (See also *P. J.*, 1917, xcviii, 275.)

In *Z. caribæum,* the lactone *carixanthide,* $C_{12}H_{24}O$, has been found. In *Z. carolinianum,* the lactone *carolixanthide,* $C_{20}H_{19}O_6$, has been reported. In *Z. americanum* Witte found *xanthoxyloin,* $C_{14}H_{14}O_4$. Giacosa and Soave extracted from *Z. senegalense,* a lactone, $C_{13}H_{10}O_3$. Streglitz believes this to be identical with *xanthotoxin,* found by him in the fruit of the same species and to which he ascribes the formula $C_{12}H_8O_4$.

Several species of this genus, including the official, yield volatile oils (see *Schim. Rep.,* April, 1911, p. 50).

Uses.—Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, and a tendency to diaphoresis. It is thought to resemble mezereum and guaiac in its remedial action, and is given in the same diseases. As a remedy in *chronic rheumatism,* it enjoys some reputation in this country. The bark, used as a masticatory, is a popular remedy for *toothache.* Xanthoxylum is also occasionally employed as a gastro-intestinal stimulant in atonic *dyspepsia, flatulence,* and serous *diarrhea.*

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Xanthoxyli, *N. F.;* Elixir Corydalis Compositum, *N. F.;* Elixir Hydrastis Compositum, *N. F.*

ZEA. N. F.

ZEA [Corn Silk]

"Zea consists of the fresh styles and stigmas of *Zea Mays* Linné (Fam. *Gramineæ*). Zea should be collected when the corn is in milk and used in the green condition for the manufacture of pharmaceutical preparations." *N. F.*

Corn Silk; Stigmata Maydis, Mais, *Fr. Cod.;* Filament de Mais, *Fr.;* Maispistille, *G.*

This drug is the so-called "silk" of the ear of ordinary *Indian corn* or *maize,* cultivated in the warmer temperate and subtropical countries of the world.

Description and Physical Properties.—"In slender filaments from 10 to 20 cm. in length, and about 0.4 mm. in diameter; of a light green, purplish red, yellow or light brown color; stigmas bifid, the segments very slender, frequently unequal and from 0.4 to 3 mm. in length.

"*Structure.*—Styles consisting for the most part of parenchyma and two parallel vascular bundles with narrow, spiral or annular tracheæ; the epidermal cells rectangular, many of these being extended into multicellular hairs, the latter being from 0.2 to 0.8 mm. in length, the basal portion consisting of two to five united cells, the upper portion being usually unicellular; the cells of the hairs are rich in cytoplasm and usually contain a small, spherical nucleus; the purplish red styles contain a purplish red cell sap.

"Digest a small portion of the fresh styles and stigmas in diluted alcohol and filter; a pale purplish red solution is produced, separate portions of which, on the addition of acids, become distinctly purplish or yellowish red; on the addition of alkalies, green; on the addition of ferric chloride T.S., olive-green changing to greenish brown; and on the addition of an aqueous solution of alum, bluish or purplish, the color being quite permanent." *N. F.*

Rademaker and Fischer (*A. J. P.,* 1886, p. 369) determined the presence of 2.25 per cent. of *maizenic acid* in dried corn silk. It was first described, however, by Vautier. It is freely soluble in water, alcohol and ether, but insoluble in benzin. Rademaker and Fischer found, in addition to the acid, fixed oil, resin, chlorophyll, sugar, gum, extractive, albuminoids, phlobaphene salt, cellulose and water.

Uses.—Zea is employed in *acute* and *chronic cystitis* and in the bladder irritation of *uric acid* and *phosphatic gravel.* It has also been employed in *gonorrhea,* and has been affirmed by Landreux to be a useful diuretic and even cardiac stimulant in the *dropsy of heart disease.* It probably is, however, of little value.

Concerning the activity of *maizenic acid* we have little definite knowledge, but it probably represents whatever physiological power the drug possesses; it has been given in the *dose* of one-eighth of a grain (0.008 Gm.).

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Fluidextractum Zeæ, *N. F.;* Elixir Sabal et Santali Compositum, *N. F.*

ZEDOARIA. N. F.

ZEDOARY

"Zedoary is the dried rhizome of *Curcuma Zedoaria* (Bergius) Roscoe (Fam. *Zingiberaceæ*). Zedoary contains not more than 2 per cent. of foreign organic matter." *N. F.*

Zedoaria; Zedoaire, *Fr. Cod.;* Radix Zedoariæ, Rhizoma Zedoariæ, *P. G.;* Zitterwurzel, *G.*

The plant which produces this rhizome is closely related to that which produces turmeric (see *Curcuma,* Part II) and is, like that species, a native of India. It chiefly differs from *Curcuma longa* by its handsomely variegated leaves, pungent rhizome and upper bract leaves which are white and tinged with carmine. The plant is widely cultivated in India, Ceylon and China for its medicinal rhizome which is collected, washed and cut into circular disks and dried. The commercial supplies reach this country through Bombay and Trieste.

Formerly there were two kinds of zedoary, the long and the round, distinguished by the old official titles of *radix zedoariæ longæ* and *radix zedoariæ rotundæ.* The *long zedoary* was in slices, from 2.5 to 7.5 cm. in length, and from 1 to 2.5 cm. thick, obtuse at the extremities and exhibiting the remains of the radical fibers. The *round* alone is now found in commerce.

Description and Physical Properties.—"*Unground Zedoary.*—Usually cut into transverse rounded sections, twisted and wrinkled, from 1 to 4 cm. in diameter, and from 5 to 10 mm. in thickness; externally grayish brown, hairy, rough, with few root scars; transverse surface pale reddish, to gray-brown; a distinct dark circular endodermis separates the cortex from the central cylinder; the stele contains numerous, orange-colored resin cells, and irregularly distributed lighter colored fibrovascular bundles which are fewer in the cortex; fracture short, somewhat mealy and waxy. Odor aromatic, camphor-like; taste aromatic, warm, slightly bitter.

"*Structure.*—A thick cork, a thin epidermis with numerous characteristic hairs, the latter thick-walled, 1- to 6-celled, up to 1 mm. in length and often thicker in the middle than at the base; the parenchyma of the cortex and of the central cylinder rich in starch; secretion cells isodiametric with suberized walls, contents colorless or yellowish; the endodermis of small, thin-walled quadrangular cells, the fibro-vascular bundles collateral, more numerous in the central cylinder and nearer the endodermis; few bast-fibers in the cortex and no crystal cells.

"*Powdered Zedoary.*—Numerous starch grains, ovoid, from 0.010 to 0.070 mm. in length and from 0.007 to 0.030 mm. in thickness, having the point of origin of growth in the smaller end of the grain; numerous characteristic, thick-walled hairs; rich in parenchyma; very few bast fibers; no calcium oxalate crystals or stone cells." *N. F.*

Zedoary yields a volatile oil, when distilled with water, and contains a pungent soft resin and bitter extractive.

Uses.—Zedoary has a local effect upon the digestive organs similar to, but milder, than that of ginger and is occasionally employed as a gastro-intestinal stimulant in *flatulent colic* and other debilities of the digestive organs. Its official recognition, however, is due to the fact that it was an ingredient in the original Warburg's tincture and N. F. modifications.

Dose, ten to thirty grains (0.6–2 Gm.).

Off. Prep.—Pilulæ Antiperiodicæ, *N. F.;* Pilulæ Antiperiodicæ sine Aloe, *N. F.;* Tinctura Amara, *N. F.;* Tinctura Antiperiodica, *N. F.;* Tinctura Antiperiodica sine Aloe, *N. F.;* Tinctura Amara, *N. F.*

ZINCI ACETAS. U. S., Br.

ZINC ACETATE Zinc. Acet.

"Zinc Acetate contains not less than 83.16 per cent. and not more than 87.32 per cent. of $Zn(C_2H_3O_2)_2$, corresponding to not less than 99.5 per cent. of the crystallized salt [$Zn(C_2H_3O_2)_2.2H_2O$]." *U. S.* "Zinc Acetate, $Zn(C_2H_3O_2)_2,2H_2O$, may be obtained by neutralising acetic acid with zinc carbonate." *Br.*

Acetas Zincicus; Acétate de Zinc, *Fr. Cod.;* Zincum Aceticum, *P. G.;* Zinkacetat, Essigsaures Zink, Essigsaures Zinkoxyd, *G.*

A process for this salt is no longer given in the U. S. P. In the U. S. process of 1870 zinc oxide—instead of the carbonate as in the Br. process—is acted upon directly by acetic acid. During the evaporation of the solution of the zinc acetate, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. Though not economical on the large scale, these processes have the recommendation of being easily performed for supply in an emergency and of yielding a pure product.

Description and Physical Properties.—"Soft, white, six-sided, monoclinic plates, having a pearly luster, a faintly acetous odor, and, in dilute solutions, an astringent, metallic taste. When exposed to air, the salt gradually effloresces and loses some of its acid. One Gm. of Zinc Acetate is soluble in 2.3 cc. of water and in 30 cc. of alcohol, at 25° C. One Gm. is soluble in 1.6 cc. of boiling water and in about 1 cc. of boiling alcohol. When heated, Zinc Acetate is partially fused, losing water and acetic acid. At a higher temperature it is decomposed, with the evolution of inflammable and empyreumatic vapors, and leaves a residue consisting chiefly of zinc oxide.

"An aqueous solution of the salt responds to the reactions for zinc, and for acetates. An aqueous solution of the salt is neutral or slightly acid to litmus paper. A 10 cc. portion of an aqueous solution of the salt (1 in 50), to which 1 cc. of hydrochloric acid has been added, meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Dissolve about 1 Gm. of Zinc Acetate, accurately weighed, in 100 cc. of distilled water, render the solution slightly alkaline with ammonia T.S., and warm to 80° C. Completely precipitate the zinc as zinc sulphide by the addition of ammonium sulphide T.S., and warm the liquid on a water bath until the precipitate settles. Collect the latter on a filter, wash it with distilled water containing a few drops of ammonium sulphide T.S., then dissolve it in hot, dilute nitric acid (1 in 3), evaporate the solution to dryness in a tared dish, ignite the residue, and weigh it as zinc oxide. The weight of zinc oxide obtained, multiplied by 2.254, indicates its equivalent in $Zn(C_2H_3O_2)_2$. Each Gm. of Zinc Acetate corresponds to not less than 0.369 Gm. and not more than 0.387 Gm. of ZnO.

"Zinc Acetate may also be assayed by the electrolytic method.

"Preserve in well-closed containers." *U. S.*

"Thin, translucent, colorless, crystalline plates, of a pearly lustre. Taste sharp and unpleasant. Soluble in 2.5 parts of *water.* Yields the *reactions* characteristic of zinc and of acetates. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium chlorides, or sulphates. *Arsenic limit* 5 parts per million. 0.5 gramme, tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant, but if ferric oxide be present it will be left undissolved. Zinc acetate is decomposed by the mineral acids, with the escape of acetous vapors.

Uses.—Zinc acetate is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in *ophthalmia,* and as an injection in *gonorrhea,* after the acute stage in these affections has passed. The strength of the solution usually prescribed is one or two grains to a fluidounce (0.065 or 0.13 Gm. to 30 cc.) of distilled water. Rigney (*M. R.,* 1918, xxvii, 11) recommends a saturated solution for local application in *chilblains.*

ZINCI CARBONAS. Br.

ZINC CARBONATE

" Zinc Carbonate is a hydrated zinc carbonate, and may be obtained by the interaction of zinc sulphate and sodium carbonate." *Br.*

Zinci Carbonas Præcipitatus, *U. S. IX;* Precipitated Zinc Carbonate; Zinci Carbonas Præcipitata, *U. S.* 1870; Carbonate of Zinc; Zincum Carbonicum, Carbonas Zincicus; Carbonate (sous-) de Zinc Hydraté, Hydrocarbonate de Zinc, *Fr. Cod.;* Carbonate de Zinc, *Fr.;* Zinkcarbonat, Kohlensaures Zinkoxyd, *G.*

In the U. S. formula of 1870 a double decomposition takes place between zinc sulphate and sodium carbonate, resulting in the formation of sodium sulphate in solution, and basic zinc carbonate which is precipitated. Sodium carbonate is preferable to potassium carbonate for decomposing the sulphate, since the former gives rise to sodium sulphate, which is more easily washed away than the potassium sulphate derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. When a solution of zinc sulphate is precipitated by an excess of acid potassium carbonate, a normal zinc carbonate is obtained. With normal sodium carbonate, on the other hand, taken as a precipitant, a basic salt results.

Description and Physical Properties.— " White amorphous powder. No odor or taste. Insoluble in *water;* entirely soluble in *diluted nitric acid.* Yields the *reactions* characteristic of zinc and of carbonates. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, or ammonium, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic limit* 10 parts per million. 0.2 gramme, dissolved in *diluted sulphuric acid,* and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

If adulterated with chalk it will be only partly soluble in oxalic acid solution. Precipitated zinc carbonate is often sold under the incorrect name of *flowers of zinc,* a name which properly belongs only to the oxide, as obtained by combustion. When obtained from solutions of zinc sulphate and sodium carbonate it has a variable composition, as different hydrated basic carbonates are formed, according to the temperature used, etc.; the higher the temperature and the larger the quantity of water used, the more basic the carbonate becomes.

Uses.—This was introduced as a substitute for prepared calamine, but, as one of the important virtues of the native product is its pinkish color, the substitution is not a step in advance. It is used locally for much the same purpose as zinc oxide.

ZINCI CHLORIDUM. U. S., Br.

ZINC CHLORIDE Zinc. Chlor.

" Zinc Chloride contains not less than 95 per cent. of $ZnCl_2$." *U. S.* " Zinc Chloride, $ZnCl_2$, may be obtained by the interaction of hydrochloric acid and zinc." *Br.*

Butter of Zinc; Chloruretum Zincicum; Chlorure de Zinc, *Fr. Cod.;* Zincum Chloratum, *P. G.;* Zinkchlorid, Chlorzink, *G.;* Cloruro zincico, *Sp.*

Neither the U. S. nor British Pharmacopœias gives a process for making this salt; that of the Br. Pharm. 1885 follows:

" Take of Granulated Zinc *one pound;* Hydrochloric Acid *forty-four fluid ounces;* Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce,* or *a sufficiency;* Distilled Water *one pint.* Put the Zinc into a porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Test a few drops of the resulting liquid for iron or lead by adding excess of ammonia and then sulphydrate of ammonium, when a black precipitate will be produced if iron or lead be present.

" In the latter case filter the remainder of the product into a gallon bottle, and pour in the solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears, and the whole of the iron or lead is thus precipitated. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely-stoppered bottles. If no iron or lead be present, filter and evaporate, etc., at once." *Br.* 1885.

Rhighini prepares this chloride by double decomposition between solutions of barium chloride and zinc sulphate. Barium sulphate is precipitated, and zinc chloride remains in solution, from which it is obtained in white flaky crystals by due evaporation. As zinc sulphate is obtainable in considerable quantities as a cheap by-product in the washing of pyrites and other sulphide ores containing zinc, as well as from the so-called "pickle waste" solutions from brass foundries, this is sometimes used as a commercial source for the manufacture of zinc chloride. Finely ground salt is added to the zinc sulphate solution, and the mixture chilled, when the sodium sulphate produced by the reaction crystallizes out, leaving zinc chloride in solution.

Description and Physical Properties.—"A white, or nearly white, odorless, granular powder, or in porcelain-like masses, or moulded into pencils. It is very deliquescent. One Gm. of Zinc Chloride is soluble in 0.25 cc. of water and in about 1.3 cc. of alcohol, at 25° C. It is soluble in 2 parts of glycerin. When heated to about 260° C., Zinc Chloride fuses to a clear liquid. At a higher temperature (about 730° C.), it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide. An aqueous solution of the salt (1 in 10) is acid to litmus paper. An aqueous solution of the salt responds to the reactions for zinc, and for chlorides.

"Mix an aqueous solution of Zinc Chloride (1 in 20) with an equal volume of alcohol: a single drop of hydrochloric acid is sufficient to render 10 cc. of the mixture perfectly clear (*oxychloride*). Completely precipitate the zinc from a solution of 1 Gm. of the salt in 50 cc. of distilled water, by means of ammonium sulphide T.S., filter, evaporate the filtrate, and ignite gently: the weight of the residue does not exceed 0.004 Gm. A 10 cc. portion of an aqueous solution of the salt (1 in 50), to which 1 cc. of diluted hydrochloric acid has been added, meets the requirements of the test for *heavy metals.* Add ammonium carbonate T.S., in small portions, to an aqueous solution of Zinc Chloride (1 in 20): the precipitate produced is white, and redissolves completely in an excess of the reagent. Add sufficient sodium hydroxide T.S. to 5 cc. of an aqueous solution of the salt (1 in 10) to redissolve the precipitate which first forms, and then warm the solution: the odor of ammonia is not perceptible (*ammonium salts*). One Gm. of Zinc Chloride shows no more *sulphate* than corresponds to 0.3 cc. of fiftieth-normal sulphuric acid.

"**Assay.**—Proceed as directed under the assay for chlorides, using about 0.3 Gm. of Zinc Chloride, accurately weighed in a stoppered weighing bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.006815 Gm. of $ZnCl_2$. Zinc Chloride may also be assayed by the electrolytic method.

"Preserve in small, glass-stoppered bottles." *U. S.*

"Colorless opaque rods or tablets, or in granules; very deliquescent and caustic. Almost entirely soluble in *water,* in *alcohol* (90 per cent.), and in *ether.* Yields the *reactions* characteristic of zinc and of chlorides. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, or sulphates. *Arsenic limit* 5 parts per million. 0.25 gramme, tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

When pure, it is wholly soluble in water, alcohol, and ether, but often contains some oxychloride, which is left undissolved by water. There are several of these basic insoluble compounds, the so-called *oxychlorides,* of which Sorel's mass, Zn.OH.Cl, is an example. These are used for cements and as a filling for teeth. Zinc chloride has a strong tendency to combine with organic bases, forming crystallizable compounds, as with strychnine, morphine, quinine, cinchonine, etc., in this respect resembling certain other metallic chlorides, as platinum, palladium, gold, and mercury chlorides. (*J. P. C.,* 4e sér., iii, 56.) When exposed to heat, zinc chloride first melts and then sublimes. It has been obtained in small deliquescent octahedrons of the formula $ZnCl_2 + H_2O$, by evaporating its hydrochloric acid solution to a syrup, and then adding a little concentrated hydrochloric acid. It consists of one atom of zinc and two of chlorine.

Josiah C. and Bertha L. de G. Peacock (*Proc. Pa. Ph. A.,* 1918, xli, 155) conclude "that the separation of zinc oxychloride when zinc chloride is dissolved in water is always accompanied by liberation of free hydrochloric acid which remains in the solution; at the same time a loss of zinc is experienced. Both of these objections may be overcome in solutions up to approximately twenty grains to the ounce by the use of boric acid, weight for weight of zinc chloride taken. For solutions exceeding this strength, or for any strength, ammonium chloride in quantity of not less than one-fifth of the amount of zinc chloride used, will insure complete and permanent solution. Camphor water will dissolve a few grains of zinc chloride per ounce." Broeksmit (*Ph. Wb.,* 1918, lv, 1409) in order to obtain a solution free from zinc oxychloride, one which remains clear on diluting with water, recommends reducing 21.1 grammes of zinc sulphate and 7.9 grammes of barium chloride separately to fine powders, mixing them well and adding to the mixture 100 grammes of water. The mixture is then filtered. The liquid thus obtained contains about 8 per cent. of zinc chloride. (*Pharm. Weekblad.*)

Uses.—Zinc chloride has been used internally in *scrofula, epilepsy, chorea,* and other nervous diseases, but is of little or no value. Its chief use has been as an escharotic in *cancerous affections.* As a caustic it has the advantage of not causing constitutional disorder from absorption. Canquoin prepared zinc chloride as an escharotic by thoroughly and quickly mixing it with wheat flour and water into pastes of four different strengths, containing severally an ounce of the chloride incorporated with two, three, four, and five ounces of flour, fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. According to the French Codex, *Caustique au Chlorure de Zinc* (*Canquoin's Paste*) is prepared by dissolving 8 parts of zinc chloride in 1 part of cold water and incorporating a mixture of 6 parts of flour with 2 parts of zinc oxide.

P. Carles states that the official paste is too hygroscopic; he triturates in a mortar 10 grammes of fused zinc chloride with 2 grammes of 60 per cent. alcohol, and incorporates, with constant trituration, 15 grammes of wheat flour. This mass may be formed into cylinders of suitable size, and when once dry is but little affected by atmospheric humidity.

It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness and strength of the paste, the length of the application, and the nature of the part acted on. The surrounding skin should be protected from the caustic by a thickly-spread dressing of simple cerate.

Felix's Caustic Paste (*L. L.*, vol. ii, 1887) is made according to the following formula: Starch, 37 grammes; Wheat Flour, 112 grammes; Mercuric Chloride, 1 gramme; Dry Zinc Chloride, 110 grammes; pure Iodol, 10 grammes; Croton Chloral, 10 grammes; Camphor Bromide 10 grammes; Crystallized Carbolic Acid, 10 grammes; Distilled Water, sufficient to form a stiff homogeneous paste. The hand should be wetted when applying it. The paste is allowed to remain on from six to twenty-four hours, according to the amount of eschar it is desired to form.

Instead of flour, Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous calcium sulphate in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Cock, of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action and does not run. It may be prepared as a caustic seton by thickly covering a waxed cotton wick with Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of Ancrenis, of Lyons. A thread is wound spirally around the cylinder to give it firmness.

Zinc chloride is an active antiseptic. Sternberg found that a 2 per cent. solution destroyed vegetative organisms in two hours, but Koch found that a 5 per cent. solution would not kill anthrax spores in thirty days. Miquel found that in bacteriostatic power it excelled carbolic acid. Its solutions although irritant to the skin are not injurious to iron, brass, wood, or most ordinary fabrics. It has also the advantage of being deodorant, on account of its attraction for hydrogen sulphide, and is widely employed, frequently in mixtures with other substances, as a commercial disinfectant.

It is the principal active constituent in many proprietary forms of astringent mouth wash. About 1 per cent. of zinc chloride is usually present in an aqueous solution flavored with aromatic and antiseptic oils.

In overdoses, zinc chloride acts as a corrosive poison, producing burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. The antidotes are weak alkalies, or their carbonates, and, if these are not immediately at hand, soap may be used.

ZINCI OLEOSTEARAS. Br.

ZINC OLEOSTEARATE

"Hard Soap, 200 *grammes;* Curd Soap, 100 *grammes;* Zinc Sulphate, 100 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the Soaps in one thousand five hundred millilitres of the Distilled Water by the aid of heat; add to the solution the Zinc Sulphate previously dissolved in two hundred millilitres of the Distilled Water. Collect the precipitate, wash it with Distilled Water until the washings are free from sulphates, dry it, and reduce it to a fine powder." *Br.*

It is officially described as "a white amorphous powder. Odor faint, resembling that of fat. Insoluble in *water,* in *alcohol* (90 per cent.), and in *ether.* Ash about 13 per cent. The ash, dissolved in *hydrochloric acid* and the solution neutralised, yields the *reactions* characteristic of zinc. When 0.5 gramme is heated with 0.5 millilitre of *hydrochloric acid* diluted with 0.5 millilitre of *water,* a mixture of fatty acids is liberated and floats on the surface of the aqueous liquid; this aqueous liquid, filtered, neutralised with *solution of ammonia,* treated with excess of *solution of ammonium hydrosulphide,* again filtered, evaporated to dryness, and the product gently ignited, leaves no appreciable residue (absence of fixed alkalies and of alkaline earths)." *Br.*

For a process for zinc oleostearate by F. E. Niece in which he uses oleic and stearic acids and solution of zinc acetate, see *Proc. Penna. Pharm. Assoc.,* 1902, 135.

Uses.—Zinc oleostearate is used for the same purposes as zinc stearate.

ZINCI OXIDUM. U. S., Br.

ZINC OXIDE Zinc. Oxid.

"Zinc Oxide, when freshly ignited, contains not less than 99 per cent. of ZnO." *U. S.* "Zinc Oxide, ZnO, may be obtained from metallic zinc by combustion in air." *Br.*

Flores Zinci; Oxydum Zincicum; Oxyde de Zinc, *Fr. Cod.;* Blanc de Zinc, Fleurs de Zinc, *Fr.;* Zincum Oxydatum, *P. G.;* Philosophenwolle, Zinkblumen, Zinkoxyd, *G.;* Oxido zincico, *Sp.*

Preparation.—The British Pharm., 1885, and the U. S. P., 1870, prepared the zinc oxide from the carbonate already formed. By referring to the article on precipitated zinc carbonate, it will be found that it is obtained in the process from zinc sulphate, by the decomposing influence of sodium carbonate. Other methods of obtaining the zinc carbonate are by the mutual decomposition of the sodium chloride and carbonate and the ammonium sulphate and carbonate, but the former official plan is preferred. The zinc carbonate, in whatever way obtained, is exposed to heat to drive off the carbon dioxide and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary, a temperature between 280° and 300° C. being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

Zinc oxide may also be obtained by the combustion of the metal. Zinc melts at 433° C., and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. This form was at one time called *pompholix, nihil album, lana philosophica,* and *flowers of zinc.* Zinc oxide for use as a pigment has been very largely produced from calamine by the so-called "furnace and bag" process, at Bethlehem, Pa., by the Lehigh Zinc Company. The process consists essentially in calcining a mixture of finely ground calamine and a coal in a specially constructed furnace; the resultant zinc oxide rises, and passes through a huge combustion flue to a large circular tower, 50 feet high, in which the oxide and ashes separate, the latter falling to the bottom while the oxide is forced onward by fans through a "cooling-room," heated to from 204.8° to 371.1° C. into the "bag room" where it is deposited in large muslin bags.

Description and Physical Properties.—"A very fine, odorless, amorphous, white or yellowish-white powder, free from gritty particles. It gradually absorbs carbon dioxide from the air. Zinc Oxide is insoluble in water and in alcohol. It dissolves in dilute acids, in ammonia T.S. and in ammonium carbonate T.S. When strongly heated, it assumes a yellow color which disappears on cooling. A solution of Zinc Oxide in a slight excess of diluted hydrochloric acid responds to the reactions for zinc.

"Mix 1 Gm. of Zinc Oxide in a flask with 10 cc. of boiling, distilled water and add 2 drops of phenolphthalein T.S.: not more than 1 cc. of tenth-normal hydrochloric acid is required to discharge any red color that may be produced (*alkali*). Mix 2 Gm. of Zinc Oxide with 10 cc. of distilled water, add 30 cc. of diluted sulphuric acid, and heat on a water bath with constant stirring: no effervescence occurs (*carbonate*), and the resulting solution is clear and colorless. Five cc. portions of the cooled solution yield white precipitates with potassium ferrocyanide T.S. or with sodium sulphide T.S. (*iron and many other metals*). Add 2 Gm. of Zinc Oxide to 20 cc. of distilled water, and after stirring well, add 5 cc. of glacial acetic acid, and warm upon a water bath until solution is effected: the addition of 5 drops of potassium chromate T.S. produces no turbidity or precipitate (*lead*).

"**Assay.**—Digest about 1.5 Gm. of freshly ignited Zinc Oxide, accurately weighed, with 50 cc. of normal sulphuric acid until solution is complete. Then titrate the excess of sulphuric acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.04069 Gm. of ZnO. Zinc Oxide may also be assayed by the electrolytic method." *U. S.*

"A soft, white or nearly white, amorphous powder, becoming pale yellow when heated. No odor or taste. Yields the *reactions* characteristic of zinc. Soluble in *diluted hydrochloric acid* without the separation of any black particles. Yields no characteristic *reactions* for copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, and only slight *reactions* for lead and carbonates. *Arsenic limit* 10 parts per million. 0.2 gramme, dissolved in *diluted sulphuric acid,* and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

Commercial zinc oxide such as is manufactured for use as a pigment is usually contaminated with cadmium or lead, or both. It should never be employed for medicinal purposes. LaWall (*Proc. N. J. Ph. A.,* 1917, xlvii, 74) states that in many samples of zinc oxide, lead is present to the amount of from 0.1 to 0.5 per cent. and advises the rejection of all samples labelled "U. S. P. in all respects except the heavy metal test." He suggests the following methods for examination: Dissolve 5 grammes of the sample of zinc oxide in a slight excess of diluted sulphuric acid, with gentle heat; collect and wash the precipitate with distilled water; then pour through the filter containing the precipitate a concentrated solution of ammonium acetate (about 25 per cent.) freshly made, and to this filtrate which now contains the lead in a soluble form add a slight excess of solution of potassium chromate which will precipitate insoluble lead chromate which may be collected on counterpoised filters, or on a Gooch crucible mat, washed, dried, weighed and calculated as to its percentage. A more expeditious method which gives good results with the amount of lead usually found at the present time is to simply dissolve 5 or 10 grammes of the sample of an excess of acetic acid and then perform the precipitation with potassium chromate in this solution directly, and collect, wash and weigh the precipitate as before. This latter modification will give low results, however, where part of the lead is present in the form of sulphate as is often the case, as the sulphate will remain behind when the solution is made in acetic acid.

The U. S. P. X has adopted the second test described. The market conditions have improved somewhat and U. S. P. quality zinc oxide is now available to a much greater extent than when the condition described above was reported.

Zinc oxide, prepared by combustion, called commercial zinc oxide, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discolored by hydrogen sulphide. It is stated that it has greater covering power as a color than white lead, 10 parts being equal to 13 of white lead. It is, however, dearer, so that the pure oxide has not replaced white lead. This form of oxide, even though pure, is often unsuited for medical uses, because of lack of smoothness and the presence of gritty particles. There is an English preparation known as *Griffith's zinc white,* or *lithophone,* made by precipitating zinc sulphate by barium sulphide; it is, therefore, a mixture of zinc sulphide and barium sulphate. If this be roasted in a current of superheated steam the zinc sulphide will be converted into zinc oxide. This process has been patented in Germany by Meissner. (Wagner's *Chem. Technol.,* 11th ed., p. 159.)

Uses.—Zinc oxide has been used as an antispasmodic in *chorea, epilepsy,* and *whooping-cough,* but is probably of little value as a systemic remedy. It is also sometimes employed for its astringent and sedative properties in *diarrhea.* Its most important use, however, is as an application to excoriated surfaces and in various *skin diseases.* It owes its popularity to a combination of four qualities: it is non-toxic, protective, mildly astringent and probably antiseptic. It may be applied as a dusting powder—usually in conjunction with talcum—suspended in aqueous mixtures or in the form of ointment. (See *Unguentum Zinci Oxidi.*) As a cosmetic it has the great advantage over the preparations of lead of not being poisonous.

Dose, two to five grains (0.13–0.32 Gm.), preferably in pill form.

ZINCI PHENOLSULPHONAS. N. F.

ZINC PHENOLSULPHONATE Zinc. Phenolsulph. [Zinc Sulphocarbolate]

"Zinc Phenolsulphonate contains not less than 73.7 per cent. and not more than 77.4 per cent. of anhydrous zinc phenolsulphonate, corresponding to not less than 99.5 per cent. of the crystallized salt ($(C_6H_5O.SO_3)_2Zn.H_2O$ = 555.76)." *N. F.*

Zinci Sulphocarbolas, *Br.* 1898; Zincum Sulphophenolicum; Zinc Paraphenolsulphonate.

Description and Physical Properties.—"Zinc Phenolsulphonate occurs as colorless, transparent, rhombic prisms or tabular crystals, or in granular form; odorless, and having an astringent, metallic taste. When exposed to the air the salt effloresces, and upon exposure to light and air may become slightly pink. One Gm. of Zinc Phenolsulphonate dissolves in 1.6 cc. of water, and in 1.8 cc. of alcohol at 25° C.; also in 0.4 cc. of boiling water.

"Its aqueous solution (1 in 10) is acid to litmus. When heated to 125° C., the salt loses all of its water of crystallization. At a higher temperature it chars, emitting inflammable vapors having the odor of phenol, and finally leaves an incombustible residue. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S. Ammonium carbonate T.S., when added in small portions to an aqueous solution of the salt (1 in 20), produces a white precipitate which redissolves completely upon the addition of an excess of the reagent. A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S.

"The addition of a few drops of barium chloride T.S. to 10 cc. of aqueous solution of the salt (1 in 20), previously acidulated with 3 drops of hydrochloric acid, produces not more than a slight turbidity (*sulphate*). Ten cc. of an aqueous solution of the salt (1 in 50), to which 1 cc. of diluted hydrochloric acid has been added, does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 1 Gm. of Zinc Phenolsulphonate, accurately weighed, in 100 cc. of distilled water, render the solution slightly alkaline with ammonia water and warm it to 80° C. Completely precipitate the zinc as zinc sulphide by the addition of ammonium sulphide T.S. and warm the liquid on a water-bath until the precipitate settles. Collect the precipitate on a filter, wash it with distilled water containing a few drops of ammonium sulphide T.S., then dissolve it in hot dilute nitric acid (1 in 3), evaporate the solution in a tared porcelain or platinum dish, ignite the residue and weigh it as zinc oxide. The amount of zinc oxide obtained multiplied by 5.059 indicates its equivalent in $Zn(C_6H_5SO_4)_2$. Zinc phenolsulphonate may also be assayed by the electrolytic method (see U. S. P. X).

"Preserve it in small, well-closed containers." *N. F.*

Uses.—Zinc phenolsulphonate has been employed as an antiseptic and astringent application to indolent or foul *ulcers,* and in subacute inflammations of the mucous membrane. The solutions used may be a little stronger than those of zinc sulphate employed for similar purposes. It has also been used as an intestinal antiseptic.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Liquor Iodi et Zinci Phenolsulphonatis, *N. F.*

ZINCI STEARAS. U. S.

ZINC STEARATE Zinc. Stear.

"Zinc Stearate is a compound of zinc with stearic acid and variable proportions of palmitic acid, corresponding to not less than 13 per cent. and not more than 15.5 per cent. of ZnO." *U. S.*

Stéarate de Zinc, *Fr.;* Zinkstearat, Stearinsaures Zinkoxyd, Talgsaures Zinkoxyd, *G.*

(See *Zinci Oleostearas,* Br.)

Zinc stearate may be made by mixing a solution of sodium stearate with one of zinc acetate, at a temperature of 50° C., washing, and then drying the precipitate.

Description and Physical Properties.—"A fine, white, bulky powder, free from grittiness, and having a faint characteristic odor. Zinc Stearate is insoluble in water, alcohol, and ether. When heated, the salt fuses. At a higher temperature it is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaving a residue consisting chiefly of zinc oxide. Heat 1 Gm. of Zinc Stearate with a mixture of 25 cc. of distilled water and 5 cc. of hydrochloric acid: stearic acid is liberated and floats as an oily layer on the surface of the liquid, and the aqueous layer responds to the reactions for zinc.

"The salt is neutral to moistened litmus paper. Boil 1 Gm. of Zinc Stearate with 25 cc. of distilled water and 5 cc. of hydrochloric acid, filter while hot, and wash the filter with 25 cc. of hot distilled water. Render the filtrate alkaline with ammonia T.S., warm to 80° C., and add ammonium sulphide T.S. in excess. Filter, evaporate the filtrate to dryness, and ignite the residue. Dissolve this residue in 10 cc. of hot distilled water, filter, again evaporate, ignite, and weigh. Not more than 1 per cent. of residue remains (*alkalies or alkali earths*). The insoluble residue of fatty acids obtained in the preceding test, when well washed and dried over sulphuric acid, melts at a temperature not below 56° C.

"**Assay.**—Boil about 1 Gm. of Zinc Stearate, accurately weighed, with 50 cc. of tenth-normal sulphuric acid for ten minutes, cool, and filter. Wash the filter and flask thoroughly with distilled water and titrate the excess of sulphuric acid with tenth-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.004069 Gm. of ZnO." *U. S.*

Uses.—Zinc stearate is employed in *eczema, acne* and other cutaneous diseases, in the form of powder, or made into an ointment. It has been largely used in the nursery as a substitute for talcum powder, but according to a special committee of the American Medical Association (*J. A. M. A.,* 1925, lxxxiv, p. 750) possesses no superiority over talcum and a number of fatal cases of pulmonary inflammation have been reported by Heiman and Aschner (*Am. J. Dis. of Children,* 1922, xxiii, p. 503) from inhalation of zinc stearate powder.

Off. Prep.—Unguentum Zinci Stearatis, *N. F.*

ZINCI SULPHAS. U. S., Br.

ZINC SULPHATE Zinc. Sulph.

"Zinc Sulphate contains not less than 55.86 per cent. and not more than 58.63 per cent. of $ZnSO_4$, corresponding to not less than 99.5 per cent. of the crystallized salt [$ZnSO_4.7H_2O$]." *U. S.* "Zinc Sulphate, $ZnSO_4,7H_2O$, may be obtained by the interaction of diluted sulphuric acid and zinc." *Br.*

Sulfas Zincicus, Vitriolum Album; White Vitriol; Sulfate de Zinc officinal, *Fr. Cod.;* Zincum Sulfuricum, *P. G.;* Zinksulfat, Schwefelsaures Zinkoxyd, Weisser Vitriol, Galitzenstein, *G.;* Solfato di zinco, *It.;* Sulfato zincico, *Sp.*

The Pharmacopœias no longer give detailed processes for preparing this salt.

Zinc sulphate is used industrially for the preservation of wood and of hides and for rendering fabrics fire proof. It is also used as a mordant in textile printing.

Preparation on the Large Scale.—Impure zinc sulphate, as it occurs in commerce, is called *white vitriol.* It is manufactured by roasting *blende* (native zinc sulphide) in a reverberatory furnace. This mineral, besides zinc sulphide, contains small quantities of iron, copper, and lead sulphides, and by roasting is converted, in consequence of the oxidation of its constituents, into zinc sulphate, mixed with iron, copper, and lead sulphate. The roasted matter is then lixiviated, and the solution obtained, after having been allowed to settle, is concentrated by evaporation, so that, on cooling, it may concrete into a white crystalline mass. In this state it always contains ferrous sulphate, and sometimes a small proportion of copper sulphate. It may be purified from these metals by dissolving it in water and boiling the solution with zinc oxide, which converts the iron and copper sulphates into zinc sulphate and the respective hydroxides of iron and copper. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron. F. Stolba recommends a process which has been used successfully for the purification of zinc sulphate by the use of zinc carbonate and zinc permanganate.

The official crystalline zinc sulphate contains seven molecules of water of crystallization; the *white vitriol* of commerce contains but three molecules of water.

The impure commercial variety of zinc sulphate is in the form of irregular white masses having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by ferric compounds. It is less soluble than the official salt, on account of its containing less water of crystallization.

Description and Physical Properties.—"Colorless, transparent, rhombic crystals, or a granular, crystalline powder, without odor, and having an astringent, metallic taste. It is efflorescent in dry air. One Gm. of Zinc Sulphate is soluble in 0.6 cc. of water and in 2.5 cc. of glycerin, at 25° C. It is insoluble in alcohol. When rapidly heated, Zinc Sulphate melts. When strongly ignited, it is partly decomposed, losing both water and sulphuric acid. Its aqueous solution (1 in 10) is acid to litmus paper. An aqueous solution of the salt responds to the reactions for zinc, and for sulphates.

"A 10 cc. portion of an aqueous solution of Zinc Sulphate (1 in 50), acidulated with 1 cc. of diluted hydrochloric acid, meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.* An aqueous solution of Zinc Sulphate (1 in 20) is not colored pink by methyl orange T.S. (*free acid*). One Gm. of Zinc Sulphate shows no more *chloride* than corresponds to 0.3 cc. of fiftieth-normal hydrochloric acid. Dissolve 1 Gm. of Zinc Sulphate in 50 cc. of distilled water, precipitate the zinc completely by means of ammonium sulphide T.S., filter, evaporate the filtrate to dryness, and ignite: the weight of the residue does not exceed 0.5 per cent. (*alkalies or alkali earths*).

"**Assay.**—Proceed as directed under *Zinci Acetas,* using 1 Gm. of Zinc Sulphate. The weight of zinc oxide obtained, multiplied by 1.984, indicates its equivalent in $ZnSO_4$. Each Gm. of Zinc Sulphate corresponds to not less than 0.2815 Gm. and not more than 0.2955 Gm. of ZnO. Zinc Sulphate may also be assayed by the electrolytic method.

"Preserve in well-closed containers." *U. S.*

"Colorless, transparent, prismatic crystals. Taste metallic, styptic. Soluble in less than 1 part of *water.* Yields the *reactions* characteristic of zinc and of sulphates. Yields no characteristic *reactions* for lead, copper, cadmium, aluminium, calcium, magnesium, sodium, potassium, ammonium, or acetates, and not more than the slightest *reactions* for iron or chlorides. *Arsenic limit* 5 parts per million. When 0.5 gramme is dissolved in *water,* excess of *solution of ammonia* added, and the mixture allowed to stand, any precipitate that is obtained being filtered off and dissolved in *diluted nitric acid,* then this acid solution, diluted with *water* to about 15 millilitres and heated to boiling, does not acquire more than a faint pink coloration on the addition of 1 millilitre of *N/10 solution of silver nitrate* and 10 millilitres of an aqueous solution (1 in 10) of *ammonium persulphate* (limit of manganese)." *Br.*

Zinc sulphate is incompatible with alkalies and alkaline carbonates, sulphides, lime water, the soluble lead salts, and astringent infusions.

Uses.—Internally, zinc sulphate is, at present, employed only for its emetic action. Because of the promptness and certainty of its effect and its comparative freedom from danger it is one of the most valuable vomitants we possess in various *poisonings.* Schwarz and Alsberg (*J. P. Ex. T.,* 1923, xxi, 1) from experiments on the lower animals conclude that the emetic dose of zinc sulphate depends on the amount of gastric contents rather than on the relation to body weight. They estimate that a dose of thirty grains (2 Gm.) should be sufficient to vomit a man even if the contents of the stomach were 300 cc. There is a wide discrepancy between the fatal doses by mouth and by injection, due to poor absorption; based on their observations on rats, cats and dogs the lethal dose for a man would be about one ounce (30 Gm.).

Externally, it is used as an active astringent, mild caustic, or disinfectant. Its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in *fluor albus* and *gonorrhea,* and as a collyrium in *ophthalmia,* also as a stimulant application to *ulcers* both of the mucous membrane and of the skin. Simpson, of Edinburgh, employed dried zinc sulphate in the form of powder, paste, or ointment, as a powerful, rapid, manageable, and safe caustic in indurated inflammatory ulcers of the cervix uteri, in *lupus,* in *ulcerous forms of skin diseases,* and in removing *urethral caruncles, condylomata, warty excrescences,* etc. The dried salt should be finely levigated. The caustic paste is made by incorporating an ounce of the powder with a drachm of glycerin; and the caustic ointment, by thoroughly mixing the same quantity of the powder with two drachms of lard.

Zinc sulphate, in an overdose, acts as an irritant *poison.* Besides vomiting and incessant retching, it produces anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt, the patient being generally relieved by its prompt expulsion in vomiting. Death is said to have been caused, however, by an ounce and a half. The treatment consists in the administration of an alkaline carbonate, such as sodium or potassium carbonate, followed by the free use of demulcents as white of egg or mucilage of acacia. Opium is of use to allay excessive vomiting. Other symptoms should be treated as they arise.

Dose, from one-fourth to one-half grain (0.016–0.032 Gm.); as an emetic, from ten to thirty grains (0.65–2.0 Gm.). When used as a collyrium, an injection, or a gargle, or as a wash for indolent ulcers, from one to three grains (0.065–0.2 Gm.) or more may be dissolved in a fluidounce (30 cc.) of water. For medicinal purposes the crystallized salt only should be used.

Off. Prep.—Lotio Alba Veterinaria, *N. F.;* Mistura Adstringens, *N. F.;* Pulvis Antisepticus, *N. F.*

ZINCI VALERIANAS. Br.

ZINC VALERIANATE

"Zinc Valerate, $Zn(C_5H_9O_2)_2,2H_2O$, may be obtained by saturating iso-valerianic acid with zinc carbonate, or by the interaction of zinc sulphate and sodium iso-valerianate." *Br.*

Zinci Valeras, *U. S. IX;* Zinc Valerate, *Br.;* Zincum Valerianicum, *Fr. Cod.;* Valerianas Zincicus; Valérianate de Zinc, Valérate de Zinc, *Fr.;* Zincvalerianat, Baldriansaures Zinkoxyd, *G.;* Valerianato zincico, *Sp.*

This salt has been dropped by the U. S. but is recognized by the Br. No method for preparing this salt is now official; for formulas, see *U. S. Dispensatory,* 19th edition, p. 1359.

Description and Physical Properties.—It is officially described as "white, pearly, tabular crystals. Disagreeable odor; taste metallic. Very slightly soluble in cold *water,* or in *ether;* soluble in hot *water,* and in *alcohol* (90 per cent.). Yields, when heated to redness, after moistening with a small quantity of *nitric acid,* not less than 26 or more than 27 per cent. of zinc oxide. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, acetates, or carbonates, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic limit* 5 parts per million. When heated in a retort with *diluted sulphuric acid* it yields a distillate which, when added to *a solution of copper acetate,* does not immediately become turbid or opalescent, but forms after a short time oily drops, which gradually pass into a bluish-white crystalline deposit (absence of butyrates). 0.2 gramme of the zinc oxide obtained on incineration, dissolved in *diluted sulphuric acid,* and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

"It has the odor of valeric acid, and a sweetish, astringent, and metallic taste. On exposure to the air, it slowly loses valeric acid and becomes partially insoluble in water. One Gm. of Zinc Valerate dissolves in 70 mils of water at 25° C., usually leaving an insoluble residue of basic salt; soluble in 22 mils of alcohol at 25° C. Its aqueous solution (1 in 100) is acid to litmus. When gently heated, the salt melts. At a higher temperature it is decomposed, giving off inflammable vapors, and finally leaving a residue consisting chiefly of zinc oxide." *U. S. IX.*

Assay.—The U. S. IX gave the following process: "Dissolve about 1 Gm. of Zinc Valerate, accurately weighed, in 100 mils of distilled water, with the aid of a few drops of hydrochloric acid, if necessary, and estimate the zinc as zinc oxide by the method given in the assay under *Zinci Acetas.* The salt yields an amount of zinc oxide corresponding to not less than 99 per cent. of $Zn(C_5H_9O_2)_2 + 2H_2O$.

"Each gramme of Zinc Valerate corresponds to not less than 0.265 Gm. of ZnO. Zinc Valerate may also be assayed by the Electrolytic method." *U. S. IX.*

The salt, as obtained by the British, 1885, and U. S. P., 1870, formulas, contained one molecule of water; but when formed by saturating zinc carbonate, made into a paste with water, with valeric acid, it contains six molecules of water, and when dried at 50° C., perfectly resembles the official salt. (Wittstein.) Other authorities (Flückiger, *Pharm. Chem.,* and Roscoe and Schorlemmer's *Chem.,* vol. iii, Part I) gave the formula of the stable crystallized salt as $Zn(C_5H_9O_2)_2 + 2H_2O$.

Uses.—This salt has been used in *neuralgia, epilepsy,* and other nervous diseases, but is probably without therapeutic value. It has also been suggested for *diabetes insipidus.*

Dose, one to two grains (0.065–0.13 Gm.), repeated several times a day, and given in the form of pill.

ZINCUM.

ZINC Zinc.

Speltrum; Zinc pur, *Fr. Cod.;* Speltre, Zinc, *Fr.;* Zink, *G.;* Zinco, *It.;* Zinc, *Sp.*

Metallic zinc is no longer official. It occurs native in two principal states, as a sulphide, called *blende,* and as a carbonate or silicate, to which the name of *calamine* is applied indiscriminately, although the name belongs properly only to the latter. In this country there are two additional ores that are worked for zinc. Both occur at Franklin and Mine Hill, New Jersey, and are characteristic of those localities. They are the native oxide, called *red oxide* or *zincite,* and a mixture of zinc oxide with manganese and iron oxide, known as *franklinite.* Zinc has been detected in the vegetable kingdom in a peculiar violet, *Viola calamina,* growing on the calamine hills of Rhenish Prussia. It is largely produced in Belgium, Germany, and this country, the chief American localities being the southwestern section of Missouri, together with the neighboring counties of Kansas, the New Jersey localities before mentioned, Lehigh County (Pennsylvania), Virginia, Wisconsin and Montana. The metal is extracted generally from blende or calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to condense the volatilized metal. The metal is then melted and run into moulds, and forms *spelter,* or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends, its upper extremity reaching a little more than half-way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below. In the arts zinc is purified sufficiently for commercial purposes without volatilization.

Zinc was described by the U. S. IX as "a bluish-white metal, showing a crystalline fracture. It occurs in the form of thin sheets, or in irregular, granulated pieces, or moulded into thin pencils, or in powder, and having a specific gravity ranging from 6.9 when it is cast to 7.2 after it is rolled. It is dissolved by diluted sulphuric or hydrochloric acid with the evolution of hydrogen, usually leaving some insoluble residue. When heated above 100° C. and not above 150° C., the metal becomes malleable and ductile; above 200° C., it becomes sufficiently brittle to be powdered in an iron mortar; at from 412° to 415° C. it melts, and at 940° C. it boils and may be readily distilled. Add 1 Gm. of Zinc to 25 mils of diluted sulphuric acid; the liberated hydrogen does not have a disagreeable odor, nor does it color a strip of paper moistened with lead acetate T.S. (*sulphur*), or with silver nitrate T.S. (*arsenic, antimony, and phosphorus*). The filtered solution is colorless, and yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S." *U. S. IX.*

Zincum Granulatum, Br. 1885. *Granulated Zinc.*—"Take of Zinc of commerce *one pound.* Heat it in an earthen crucible, and immediately the metal is fused remove the crucible from the fire and pour the fluid in a thin stream into a vessel containing about two gallons of cold water. Drain off the water and dry the granulated zinc." *Br.,* 1885.

Assay.—"Dissolve about 1 Gm. of Zinc, accurately weighed, in a slight excess of hydrochloric acid and add sufficient distilled water to make 100 mils. Dilute 10 mils of the clear solution with distilled water to make 100 mils, render it slightly alkaline with ammonia water and subsequently treat it as directed in the assay for *Zinci Acetas* for the determination of zinc oxide. The metal yields an amount of zinc oxide corresponding to not less than 99 per cent. of Zn.

"Each gramme of Zinc corresponds to not less than 1.232 Gm. of ZnO. Zinc may also be assayed by the Electrolytic method." *U. S. IX.*

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper or carbon, for galvanic combinations. Its solution in diluted sulphuric acid furnishes the readiest method for obtaining hydrogen for laboratory experimental purposes. With copper it forms *brass,* and, in the form of *sheet zinc,* it is employed to cover the roofs of houses, to line sinks, put under stoves, and for other purposes. It is also applied to the covering of iron, to protect it from oxidation, in the same manner as tin, forming what is commercially known as *galvanized iron.* A fine powder, known as *zinc dust,* obtained by the condensation of zinc vapor in the distillation of zinc from its ores, is much used in chemical laboratories as a convenient reducing agent in many reactions. Zinc should never be used for culinary vessels, as it is soluble in the weakest acids. The zinc caps on some types of glass fruit jars have been the cause of zinc poisoning when such jars have been employed for putting up pickles and relishes in which vinegar is a constituent. Zinc and its oxide are dissolved to a certain extent by water containing common salt, a double zinc and sodium chloride being produced in solution.

Although Sacher (*In. Dis.,* Dorpat, 1893) has shown that the intravenous injection of blood-soluble zinc salts acts as a depressant to the central nervous system and also to the heart, the metal itself is decidedly less toxic than many of the heavy metals. Workers in zinc factories who are exposed to the fumes of zinc—for it is to be remembered that the metal volatilizes at high temperatures—suffer with a system complex, known as "brass ague" or "zinc fever," which is characterized by cough, muscle cramp, nausea and diarrhea, often accompanied with shivering; the symptoms usually pass off within twenty-four hours. Lehmann (*Arch. f. Hygiene,* lxxii, p. 358) was unable to cause any chronic intoxication in dogs, even with large doses of zinc carbonate continued for months. It is highly improbable that any amount of zinc likely to be absorbed with food-stuffs would exercise a deleterious influence on the health.

Because of the observation of Sacher that zinc salts have a depressant action upon the central nervous system, they have been suggested as remedies for various nervous diseases, especially *epilepsy.* It is to be noted, however, that the official salts being precipitants of protein could not be absorbed into the blood stream. The clinical evidence as to the value of these salts in nervous diseases is as unsatisfactory as the pharmacologic.

ZINGIBER. U. S., Br.

GINGER Zingib.

"Ginger is the dried rhizome of *Zingiber officinale* Roscoe (Fam. *Zingiberaceæ*), known in commerce as Jamaica Ginger, Cochin Ginger, and African Ginger. The outer cortical layers are often either partially or completely removed. Ginger yields not less than 2 per cent. of non-volatile ether-soluble extractive and not less than 12 per cent. of cold water-extractive." *U. S.*

"Ginger is the scraped and dried rhizome of Zingiber officinale, *Roscoe.*" *Br.*

White Ginger; Gingembre blanc, *Fr. Cod.;* Rhizoma Zingiberis, *P. G.;* Ingwer, *G.;* Zenzero, *It.;* Jengibre (Rizoma de), *Sp.*

There are about seventy species of the genus *Zingiber,* the commercial ginger being obtained from *Zingiber officinale.* This species is a native of tropical Asia, but now extensively cultivated in tropical countries of both the Eastern and Western Hemispheres. It has been introduced into southern Florida where it thrives in rich soil and partial shade.

The ginger plant, *Zingiber officinale,* has a biennial or perennial, creeping rhizome, and an annual stem, which rises two or three feet in height, is solid, cylindrical, erect, and enclosed in an imbricated membranous sheath. The leaves are sessile, lanceolate, acute, smooth, up to eight inches long by about three-quarters of an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and, like it, is clothed with oval acuminate sheaths; but it is without foliage leaves, and terminates in an ellipsoidal, obtuse, bracteal, imbricated spike. The flowers are of a greenish-yellow color with a purple lip spotted with yellow and appear two or three at a time between the bracteal scales. The fruit is an oblong capsule. The plants mature in from nine to ten months. The rhizome of the ginger is lifted from the soil by a single thrust of the fork at the time when the stems of the plant turn white, before the rhizome has begun to get tough and fibrous. It is prepared in different ways for the market, which is an important factor in determining the appearance of the several varieties. When simply deprived of roots, and washed, it constitutes the green ginger which is used for condimental purposes. When, in addition, it is scalded in boiling water and rapidly dried, it is known as *black* ginger. There are other varieties, however, which after washing are either peeled and bleached sometimes with chlorine or sulphurous acid or coated with lime or having their cork removed from the flattened sides. But all of the medicinal gingers are dried before marketing.

In Jamaica the so-called *unbleached Jamaica,* or *white ginger,* is produced by carefully peeling the washed fresh rhizomes so that the cork and outer part of the cortex are removed. These are washed again and dried in the sun. The peeled pieces are macerated sometimes in water and sometimes in lime juice, and not rarely the color of the ginger is improved by finally coating it with chalk. (See Kilmer, *A. J. P.*, 1898, p. 65; Harris, *P. J.*, 1909, xxix, p. 379.) An inferior white ginger is produced in the East Indies. The thoroughness of desiccation is a matter of commercial importance. The moisture in ginger should not exceed 10 per cent., but in the poorer specimens may constitute one-fourth of the whole weight. In China the fresh ginger is rasped into a powder and as such dried. Formerly *East Indian ginger* was imported into the United States from Calcutta, while the *Jamaica* or *West Indian ginger* came usually through London. At present the cultivation of ginger is spread almost over the whole sub-tropical world, and the drug is produced in Jamaica, St. Lucia, Dominica and Africa, India, Cochin-China, Japan, etc.

The chief varieties of ginger grown in India are the Cochin and the Calicut, of which the Cochin is reputed to be the better grade. This occurs in two forms, viz., the whitewashed and bleached, cut or scraped and the unbleached. These gingers are sent chiefly from the ports of Cochin and Calicut of Madras to Bombay whence they are exported to England and America.

In Martinique a ginger is said to be obtained by the cultivation of *Zingiber Zerumbet* Rosc. The ginger of Siam is said to be produced by *Alpinia Galanga* Willd. and is the same drug, therefore, as the *Greater* or *Java Galanga Root.* The large, ordinary, *preserved ginger* of China is, according to C. Ford (*Kew Bulletin,* 1891) also the product of *A. Galanga.* It is made by boiling young, tender, carefully selected and decorticated rhizomes in syrup. Preserved ginger from the West Indies is made from the official plant. According to Hartwich and Swanlund, the rhizome of the *Zingiber Mioga* Roscoe, which is cultivated in China and Japan, has a taste less pungent than that of the official ginger, and distinctly recalling bergamot. Its volatile oil differs from Jamaica ginger in physical properties. In commerce the varieties of ginger are known by the place of their production. African and Cochin ginger on an average yield more resin than the other varieties.

The recent rhizome, known in commerce as "green ginger" is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash color with circular rugæ, internally yellowish-white and fleshy. It sometimes begins to grow when kept in a damp atmosphere. The *black ginger* is of the same general shape, but has a dark ash-colored wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black color, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish, the cells being filled with starch. The powder is of a light yellowish-brown color. The unbleached *Jamaica ginger* is pale yellowish-buff on the outside. The pieces are rounder and thinner, and afford when pulverized a beautiful yellowish-white powder.

The uncoated ginger of the East Indies resembles the Jamaica, but is darker, being gray rather than whitish. As the Jamaica commands a much higher price than even the uncoated East India production, the latter is occasionally altered to simulate the former. This is sometimes done by coating the exterior with calcium sulphate or carbonate, sometimes by bleaching with the fumes of burning sulphur or in other ways, by which not only the exterior but also the internal parts are rendered whiter than in the unprepared root. Powdered ginger which has been exhausted in the preparation of essence, technically known as "*spent ginger,*" is used to a large extent in the adulteration of powdered ginger. Its detection without assay of some sort is almost impossible, unless so much is present as to sensibly alter the taste of the powder. The factors needed for the detection of spent ginger are the ash and the cold water extract. The latter should not be less than 12 per cent.

Commercial gingers are known as "scraped," "decorticated," and "coated." The "scraped" gingers are those from which the cortex has been removed in whole or in part by peeling, as seen in the Jamaica, and in some Cochin and Japanese varieties. In the "coated" gingers a portion of the outer natural layers are retained as in the African, Calcutta and Calicut varieties. "Bleached" and "unbleached" gingers are also distinguished, the former being lighter in color due to careful washing or special treatment. The U. S. P. X recognizes only the Jamaica, African and Cochin gingers. Of these the Jamaica is the most aromatic and the African the most pungent.

Description and Physical Properties.—"*Unground Jamaica Ginger.*—Rhizome horizontal, laterally compressed, irregularly branched, from 4 to 16 cm. in length and from 4 to 20 mm. in thickness; the cork wholly removed; externally light brown, longitudinally striate, ends of the branches with depressed stem-scars; fracture short, fibrous, starchy and resinous; internally yellowish to light brown; odor agreeably aromatic; taste aromatic and pungent.

"*Unground Cochin Ginger.*—Cork almost or wholly removed on the flattened sides light brown to grayish-yellow, fracture shorter, less fibrous and more starchy than other varieties; internally yellowish-white; oil and resin cells vary from yellowish to brownish-red; odor aromatic, taste pungent.

"*Unground African Ginger.*—Cork partly removed on the flattened sides, leaving light brownish areas; portions with cork, longitudinally or reticulately wrinkled and grayish-brown; internally light yellow to brown; taste aromatic and strongly pungent; otherwise resembling Jamaica Ginger.

"*Structure.*—Chiefly thin-walled, starch-bearing parenchyma cells, numerous scattered secretion cells and small vascular bundles; the latter very numerous, adjacent to the inner face of the narrow endodermis, the latter separating the thin cortex from the central cylinder; secretion cells, similar in size and shape to the parenchyma cells and with yellowish or orange-colored oil or oleoresin or reddish-brown resin; vascular bundles collateral, with few tracheæ, small phloem cells and usually accompanied by fibers lying on the inner face or completely surrounding the vascular tissues; cork of several or many rows of cells in African Ginger and Cochin Ginger.

"*Powdered Ginger.*—Light yellow (Jamaica Ginger), light brown (Cochin Ginger), light brown or brown (African Ginger); starch grains numerous, from 0.005 to 0.040 mm. in diameter, occasionally up to 0.060 mm. in the long axis, nearly spherical, ovoid, ellipsoidal or pear-shaped, frequently with a characteristic beak, slightly lamellated, the hilum excentric and near the smaller end; fibers long, with rounded, pointed or notched ends, thin-walled, non-lignified or only slightly lignified, with oblique pores and, where they join the parenchyma, distinctly undulate; long fiber-like cells with suberized walls and yellowish to dark brownish-red resin-like contents occasionally present; tracheæ spiral, reticulate or scalariform and frequently non-lignified; yellowish or brownish cork cells, thin-walled, occasional in Jamaica Ginger and fairly numerous in Cochin Ginger and African Ginger.

"**Assay.**—Place 4 Gm. of ground Ginger in a 200 cc. flask, fill to the mark with distilled water, and agitate at half-hour intervals during eight hours. Then allow the mixture to stand for sixteen hours and filter. Evaporate 50 cc. of the filtrate, representing 1 Gm. of the drug, on a water bath, dry to constant weight at 100° C., and weigh. It yields not less than 12 per cent. of cold water-extractive. For non-volatile ether-soluble extractive, proceed as directed on page 1552." *U. S.*

"In flattish, irregularly branched pieces, usually from seven to ten centimetres long; each branch marked at its summit by a depressed scar. Fracture short with projecting fibres. Agreeable, aromatic odor; taste pungent. When 5 grammes of powdered Ginger are shaken with 100 millilitres of *alcohol* (90 per cent.) occasionally during twenty-four hours and filtered, 20 millilitres of the filtrate yield on evaporation not less than 0.050 gramme of residue dried at 100° C.; and when 5 grammes are similarly treated with 100 millilitres of *water*, 20 millilitres of the filtrate yield not less than 0.085 gramme of residue dried at 100° C. Ash not more than 6 per cent.; and after deduction of that portion of the ash which is soluble in *water* not more than 1.5 per cent." *Br.*

Those pieces of ginger which are very fibrous, light and friable, or worm eaten, should be rejected. The commercial powder of ginger is very frequently adulterated, rice starch, powdered ginger which has been exhausted in making preparations, and even brick dust and chalk, being used, and the loss of pungency made good by the addition of capsicum or mustard.

The odor of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost, by exposure. The morphology and pharmacognosy of ginger have been studied by Meyer (*Wissenschaftliche Drogenkunde,* vol. ii, p. 64) and Tschirch and Oesterle (*Anatomischer Atlas.,* Lief. vi, p. 109). Kraemer and Sindall have published an article on the "Microscopical and Chemical Examination of the Different Varieties of Commercial Ginger" (*A. J. P.,* 1908, p. 303). Spaeth reports on the adulteration and detection of adulterants of ginger and asserts that the more common adulterants are flour, curcuma, linseed and rapeseed cake, cayenne pepper hulls, and extracted ginger. (*Zeitschr. f. Unters. d. Nahr. u. Genussm.,* x, p. 23.)

The use of capsicum in preparations of ginger is not infrequent. When present, it may be detected by the method described under tincture of ginger.

Garnet and Grier isolated a pungent constituent from ginger which was named *gingerol* by Thresh. This was later investigated by Nomura who identified it as 4-hydroxy-5-methoxy phenylethyl-methyl ketone, and named it *zingerone.* Its composition is $C_{11}H_{14}O_3$ and it melts at 40° to 41° C. It is a crystalline solid forming characteristic combinations with sodium bisulphite, and benzoyl and acetyl derivatives. He also reports the presence of *shogaol* from *shoga,* the Japanese name for ginger. This is an unsaturated ketone and has the formula $C_{17}H_{24}O_3$. (*J. Chem. Soc.,* iii, 1917, 769 and *J. Soc. Chem. Ind.* through *Drug. Circ.,* lxiii 1919, 552.)

Constituents.—The peculiar flavor of the root appears to depend on the volatile oil, its pungency is due to a yellowish liquid called *gingerol.* This is a mixture of homologous phenols of the formula $C_{16}H_{26}O_3.(CH_2O)_n$. *Zingerone,* $C_{11}H_{14}O_3$, is crystalline and has a sweet odor and an extremely pungent taste; it is chemically related to vanillin, and is formed when gingerol is treated with baryta water. The pungency of gingerol, in contrast to that of capsicum, is destroyed by heating with alkaline hydroxides.

The volatile oil is yellow with a sp. gr. of from 0.875 to 0.890 and an optical rotation of about $-25°$ to $-45°$ (the Japanese ginger is said to yield an oil which is dextro-rotatory). It consists largely of a mixture of terpenes, camphene, phellandrene and a new sesquiterpene, which the discoverers, von Soden and Rojahn (*Ph. Ztg.,* 1900, p. 414) call zingiberene. There is also some citral, cineol and borneol in the oil.

There is present in the root a considerable proportion of starch.

Uses.—Ginger is a grateful stimulant and carminative, and is often given in *dyspepsia* and *flatulent colic.* It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. It is especially valuable in *alcoholic gastritis.* In the serous type of *diarrhea,* when due to a relaxed condition of the bowel, it is a remedy of much service but should not be employed in the presence of inflammatory conditions. The hot infusion is popularly employed under the name of "Ginger Tea" for its diaphoretic effect in *colds,* especially when accompanied with suppression of the menses. Externally it is rubefacient. Under the name of *"Essence of Ginger"* cheap alcoholic preparations of ginger were formerly sold and used as intoxicants. A number of cases of blindness produced by such use have been recorded, the amblyopia having been due to the large use of methyl alcohol in the making of these "essences." The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces (30–60 cc.).

Dose, ten to twenty grains (0.65–1.3 Gm.).

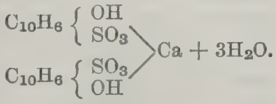
PART II

UNOFFICIAL DRUGS

In the present section it is proposed to consider remedies which are not recognized in the United States or British Pharmacopœias, but which, on account of their use in domestic or professional medicine, their toxic properties, their history, or the probability that they may prove in the future remedies of power, or valuable products, require notice in an encyclopedic work like the United States Dispensatory. The limit of the present volume forbids an exhaustive description of all these substances, but the attempt is made to give at least the essential information and the key to the literature about almost everything used in medicine.

Abrastol. *Asaprol. Calcium betanaphtholsulphonate. Calcinaphthol.*—*Calcium a-monosulphonate of β-naphthol,*



$$\left.\begin{array}{l} C_{10}H_6\left\{\begin{array}{l}OH\\SO_3\end{array}\right. \\ C_{10}H_6\left\{\begin{array}{l}SO_3\\OH\end{array}\right.\end{array}\right\rangle Ca + 3H_2O.$$

This is a pinkish powder, soluble in water and alcohol, and resembling the salicylates in its taste. It is neutral in reaction, readily soluble in alcohol and water, and not altered by heat. On exposure to light and air it tends to darken and become less soluble. It is incompatible with quinine salts, antipyrine, ferric salts, and potassium iodide, soluble carbonates and oxalates, and when rubbed with some of the synthetic drugs (exalgin, urethane, etc.), it forms a sticky mass. Asaprol was originally brought forward by A. Stackler as a germicide, antipyretic, and antirheumatic in *rheumatism, typhoid fever,* etc. (*B. G. T.*, 1892.) Dujardin-Beaumetz (*B. G. T.*, Jan., 1894) found the fatal dose, by mouth, for rabbits was a little less than 1 Gm. per kilo. In acute *rheumatism,* Dujardin-Beaumetz believed that the remedy is equal to salicylates, and that it has the advantage of not producing tinnitus aurium or eruptions upon the skin. Buck (*Ther. Woch.*, 1897) confirms the value of asaprol in *rheumatism.* Moncorvo (*B. G. T.*, March and April, 1895) recommends it in *chorea* and in *malarial diseases.* He also affirms that, used locally, it is an excellent antiseptic, hemostatic, and cicatrizant. He uses it in aqueous solution, 1 to 4 per cent., or as an ointment with vaseline. He even asserts that a 1 per cent. solution applied to the periglotteal region will rapidly cure *whooping cough.* It has been used to a limited extent as a food preservative, particularly for beverages, and is prohibited by statute in a number of states. It is detected by the yellow coloration produced by mercuric nitrate T.S. when added to the residue obtained by shaking out the acidulated solution, of the substance suspected of containing it, with ether, and evaporating the ether on a watch glass. The *dose* of abrastol is from ten to thirty grains (0.6–1.9 Gm.) three times a day.

Abroma. *Abroma angustum* L. f. (Fam. *Sterculiaceæ.*)—Under the name of *Olutkombul,* the glutinous sap of this plant has long been used in India in *dysmenorrhea.* According to Sircar (*Indian Medical Gazette,* 1900) and other English practitioners, it is an efficient remedy when given in doses of two drachms (7.7 Gm.) at the time of the first premonitory pains and continuing to the end. The fresh root is sometimes used. *Dose,* half a drachm (2 Gm.).

Abrus. *Abri Semina. Jequirity. Prayer Beads. Abrus Seeds. Abrus precatorius* L. (Fam. *Leguminosæ.*)—The seeds of this plant, which grows in India and also in Brazil, are employed in India as a standard weight by druggists and jewelers, and also for criminal poisoning. The seeds are ovoid, from 5 to 8 mm. in length, smooth, shiny and bright scarlet, having a black marking at the lower, or hilum, portion. They are said to be inert when taken whole into the stomach. They contain *abric acid,* $C_{21}H_{24}N_3O$, and according to the researches of Sidney Martin (*P. J.*, Sept., 1887; *Proc. Roy. Soc.*, 1889, vol. xlvi), two proteid poisons, a paraglobulin and an albumose (together called *abrin*), which are almost identical in their physiological properties with principles found in snake venom, although less powerful. According to Flexner, the toxic action of these substances also closely resembles that of true toxins, the most characteristic result being focal necroses in various organs. Flexner suggests that these in turn are due to a lesion in the blood-vessel walls caused by the abrin. (*J. Ex. M.*, 1897, vol. ii.) The ordinary lethal dose of abrin for animals is said to be 0.00001 Gm. per kilo of weight. Both Ehrlich and Calmette succeeded in immunizing rabbits against abrin, and obtained an antitoxic serum. The root of Abrus, known as *Indian liquorice,* possesses toxic properties like the seeds and should not be used in place of licorice. According to David Hooper, it contains *glycyrrhizin.* (*P. J.*, 1894.)

Abrin is used in the treatment of certain chronic diseases of the eye, especially in *corneal opacities,* and *trachomatous pannus.* It excites a purulent inflammation of the conjunctiva, which appears to lead to an increase in the local circulation, provoking thereby an absorption of inflammatory exudates. The remedy is capable of great harm in unsuitable cases, and extreme caution must be employed in its use. The infusion of jequirity, which was formerly employed for this purpose, has been almost abandoned because it was liable to cause an uncontrollable inflammation which in some instances has entirely destroyed vision. According to Ehrlich, the solution of abrin should not be stronger than one part in 500,000; any increase of strength must be made with great care. P. Römer (Graefe's *Archiv. f. Ophthal.*, vol. lii, 1901) has introduced two preparations: *jequiritol*, an abrin solution, sterilized, of four different strengths; *jequiritol serum*, which, as commercially supplied, has such immunizing power that 0.1 cc. suffices to protect a white mouse from the effects of a hundredfold lethal dose of jequiritol when the latter and jequiritol serum are injected conjointly. (For details and methods of use, see *Th. M.*, May, 1902; *M. R.*, 1902; Kattwinkel, *Jequiritol*, Bonn, 1902; Seefelder, *Klinische monatsblätter*, 1905, p. 273; Schoen, *Hospitalstidende*, No. 37, p. 921.)

Absinthium. *Wormwood.*—Absinthium is no longer recognized by either the U. S. P. or N. F. It was defined as: "The dried leaves and flowering tops of *Artemisia Absinthium* Linné (Fam. *Compositæ*), without the presence of more than 5 per cent. of foreign matter." *N. F. IV.*

Wormwood, also known as *Madderwort*, *Wermuth*, *Mugwort*, *Mingwort* and *Warmot*, is a shrubby, more or less herbaceous, finely canescent plant, growing to a height of 2 to 4 feet. The leaves are 1 to 3 pinnately divided, the lobes being lanceolate or obovate, the basal leaves being petiolate while the floral ones are linear and entire; the flowers are all fertile, yellowish, and occur in hemispherical panicled heads. The plant is a native of Europe and is to some extent cultivated in the United States. It is now naturalized and rather common in eastern Canada to Pennsylvania, growing along roadsides and waste places. It should be gathered in July or August, during flowering, for at this time the plant yields the greatest quantity of volatile oil. The yield of oil varies from year to year on account of varying climatic conditions.

The N. F. description was as follows: "Stems and leaves gray-green, finely silky-hairy and glandular throughout; largest leaves reaching 10 or 12 cm. in length, and of nearly equal breadth, on long petioles, two to three times pinnately lobed or divided, the ultimate segments oblong or obovate, obtuse, entire or slightly toothed; upper leaves becoming shorter petioled, small and narrower, the uppermost being only about 2 cm. in length and resembling the ultimate segments of the larger ones; heads racemose-paniculate, drooping on short peduncles, greenish-yellow, from 3 to 4 mm. in breadth, round-ovoid, the outer bracts linear-oblanceolate, obtuse, the inner broader and scarious-margined; receptacle hairy; outer flowers sometimes pistillate. Odor characteristic, aromatic; taste very bitter. The powdered drug is brownish to yellowish-green and, when examined under the microscope, exhibits numerous, characteristic, T-shaped, non-lignified hairs, consisting of a short, one- to four-celled stalk bearing a single apical cell attached near the center and up to 0.8 mm. in length and 0.035 mm. in width. Many of the hairs are more or less collapsed, twisted or broken; glandular hairs, some with one- or two-celled stalk, the glandular portions consisting of from four to eight secreting cells surrounded by a membrane; few simple hairs from the flowers, some of which are very long and up to 0.085 mm. in width; epidermal fragments with elliptical stomata, the latter up to 0.035 mm. in length; fragments of mesophyll and palisade cells containing chloroplastids; tracheæ mostly spiral, up to 0.035 mm. in width; few sclerenchymatous fibers, with thick, usually lignified walls and simple pores, up to 0.02 mm. in width; pollen grains few, somewhat spherical or triangular in outline, up to 0.03 mm. in diameter; calcium oxalate crystals in rosette aggregates about 0.01 mm. in diameter. Absinthium yields not more than 10 per cent. of ash." *N. F. IV.*

The volatile oil (*oleum absinthii*) is usually dark green, sometimes yellow or brownish or even blue, having a strong odor of the plant, an acrid peculiar taste, and the sp. gr. 0.925 to 0.950. It is sometimes adulterated with alcohol, oil of turpentine, etc., which lessen its specific gravity. It is composed of: *thujone* (*absinthol*), which has the specific gravity 0.926, composition $C_{10}H_{16}O$, boiling point 200° C. to 205° C., and when heated with phosphorus pentasulphide or zinc chloride yields cymene ($C_{10}H_{14}$); thujyl alcohol ($C_{10}H_{18}O$), both free and as the esters of acetic, isovaleric, and palmitic acids; phellandrene and possibly pinene; cadinene; and a *blue oil* fraction which is probably azulene. (Gildemeister and Hoffmann, *Aetherische Oele*, 1899.) The *absinthic acid* found by Braconnot is said to be succinic acid. Senger (*A. Pharm.*, ccxxx, p. 94) obtained a yellowish glucoside with an intensely bitter taste which he called *Absinthin.* This he found had a melting point of 55° C. and assigned to it the formula $C_{15}H_{20}O_4$, but Kromayer gives the formula as $C_{40}H_{56}O_8 + H_2O$. Absinthin is soluble in water, alcohol, and ether. *Dose*, one and one-half to three grains (0.1–0.2 Gm.). Adrian and Trillat isolated a new crystalline body ($C_{53}H_{51}O_{20}$) from wormwood by treating an alcoholic extract with amyl alcohol, the absinthin having been previously removed. They also isolated another crystalline principle, *anabsinthin*, $C_{18}H_{24}O_4$ (*P. J.*, 1899, 1, 75). The old *salt of wormwood* (*sal absinthii*) was impure potassium carbonate, made from the ashes of the plant.

Wormwood, which was formerly in vogue as a stomachic tonic, antiperiodic, and anthelmintic, is at present very seldom used. The volatile oil is an active narcotic poison. In dogs and rabbits from thirty to fifty drops (1.5–2.5 cc.) of it will cause trembling, stupor, hebetude, and even insensibility; one to two fluidrachms (3.75–7.5 cc.) of it causes violent epileptiform convulsions, with involuntary evacuations, unconsciousness, and stertorous breathing, which may or may not end in death. (Marcé, *B. G. T.*, Mai, 1864; Amory, *B. M. S. J.*, March, 1868, p. 83.) In man the oil acts similarly; a half ounce (15 cc.) of it caused, in a male adult, insensibility, convulsions, foaming at the mouth, and a tendency to vomit; though the patient recovered under the use of emetics, with stimulants and demulcents. (*L. L.*, Dec. 6, 1862.) According to J. L. Corning, the volatile oil is a powerful local anesthetic, locally useful in *rheumatic pains*. *Dose*, of wormwood in substance, from twenty to forty grains (1.3–2.6 Gm.); of the infusion (one ounce in a pint of boiling water), from one to two fluidounces

(30–60 cc.); of the oil, one to two minims (0.06–0.12 cc.).

Absinthe is a liqueur containing oils of wormwood, angelica, anise, and marjoram. According to Baudrimont, the *absinthe ordinaire* contains 47.66 per cent. of alcohol, the *demi-fine* 50 per cent., the *fine* 68 per cent., and the *absinthe Suisse* 80.66 per cent. The preparation, if manipulated properly, possesses naturally a bright green color, brought to an olive-green by slight addition of caramel coloring; but artificial coloring was formerly often resorted to, and indigo, turmeric, cupric acetate, and aniline green have been used to produce the proper shade. *Absinthism* differs from ordinary alcoholism in its manifestations; its characteristic symptoms are restlessness at night, with disturbing dreams, nausea and vomiting in the morning, with great trembling of the hands and tongue, vertigo, and a tendency to epileptiform convulsions.

Several species of Artemisia have enjoyed some reputation as medicines. The leaves of *A. Abrotanum* L., or *southernwood*, are reported by Craveri to contain a crystallizable alkaloid, *abrotine* $C_{21}H_{22}ON_2$; they were formerly employed as a tonic and anthelmintic. *A. pontica* L. has been substituted for common wormwood, but is weaker. *A. vulgaris* L., or *mugwort*, has been used in Germany in *epilepsy, chorea,* and *amenorrhea. A. ludoviciana* Nutt., a native of the southwestern regions of the United States, has been commended as a stimulant to the hair. (*A. J. P.*, 1872, p. 106.) In China, *moxa* is prepared from *A. chinensis* L. and *A. indica* Willd.

Acalypha. *Br. Add.* 1900.—The fresh and the dried herb, *Acalypha indica* L. This euphorbiaceous plant is said to have expectorant and emetic properties similar to those of ipecac, and also to be employed by the native Indian practitioners in the form of the fresh leaves as a poultice for *ulcers*, and as a suppository for *constipation* in children. The *Succus Acalyphæ*, Br. Add., 1900, was prepared by adding one volume of 90 per cent. alcohol to three volumes of the juice expressed from fresh leaves, with subsequent filtration; *dose*, from one to four fluidrachms (3.75–15 cc.). The *liquid extract* (*Extractum Acalyphæ Liquidum*, Br. Add., 1900), made with a menstruum of 90 per cent. alcohol, is given in doses of from five to thirty minims (0.3–1.8 cc.).

Acetal. *Acetol. Diethylacetal. Diethylaldehyde.* $C_6H_{14}O_2$ or $CH_3CH(OC_2H_5)_2$.—*Ethidene* (*Ethylidene*) *diethylic ether*, a limpid volatile liquid boiling at 103°–104° C., sp. gr. 0.831 at 22° C., and produced by the imperfect oxidation of alcohol. Sparingly soluble in water, readily soluble in alcohol. Used as a hypnotic in *doses* of two or three fluidrachms (8–12 cc.), preferably in emulsion.

Acetonitrile. *Methyl Cyanide.* CH_3CN. (C_2H_3N).—This is a colorless liquid, with a characteristic odor, miscible with both water and alcohol, and prepared from acetamide with glacial acetic acid by heat. Although it is probable that it is partly broken up in the system, methyl cyanide is not highly toxic. According to Lang (*A. E. P. P.*, 1894, xxxiv, p. 24), the fatal dose for rabbits is about one gramme. About one-fifth of the cyanogen which is introduced in the radical may be recovered from the urine in the form of an alkaline sulpho-cyanide. Its chief importance lies in the fact that it has been suggested by Hunt (*A. I. P. T.*, 1904, xii, p. 44) as a means for the biological standardization of the thyroid gland.

Acetophenone. *Hypnone. Phenyl-methyl-ketone. Phenylmethylacetone.* C_8H_8O or C_6H_5CO. CH_3.—A colorless liquid, boiling at 200° C., sp. gr. 1.035, having a very tenacious, persistent odor, suggesting that of bitter almonds and jasmine, not inflammable, made by distilling a mixture of calcium acetate and benzoate. It is insoluble in water or glycerine but soluble in alcohol, ether, etc., and in expressed oil of almonds.

It was originally proposed as a somnifacient but has been shown to be both uncertain as a hypnotic and toxic in its action. *Dose*, from three to ten minims (0.2–0.6 cc.). For further information see *U. S. D.*, 20th ed., p. 1225.

Acetopyrine. *Acopyrin. Pyrosal. Phenazopyrine. Antipyrinæ acetyl-salicylas.*—This occurs as a white, crystalline powder, having an acetous odor; melting point 63°–65° C.; sparingly soluble in cold but freely in warm water; freely soluble in alcohol. It was originally introduced into medicine by Winterberg and Braun (*W. K. W.*, 1900, No. 39) as combining the activities of antipyrine and acetyl-salicylic acid, into which substances, according to W. Meitner (*St. P. M. W.*, xx, 1900), it is broken up in the stomach; the acetyl-salicylic acid undergoing further decomposition in the intestines. Acetopyrine has been used as an analgesic in *migraine, neuritis,* etc., and also as an antipyretic. It has also been employed as an antirheumatic, especially in subacute and chronic cases. Goldmann (*All. W. M. Z.*, April, 1901) claims that it is valuable in *bronchitis;* and Bolognesi (*B. G. T.*, March, 1901) recommends it in *gonorrhea.* It may be given in *doses* of five to ten grains (0.32–0.65 Gm.).

Aceto-Toluid.—Two isomeric compounds, the *ortho-* and *para- Tolyl-acetamid*, $C_6H_4(CH_3)NH.C_2H_3O$, have been used in medicine for their antipyretic effects (see Barbarini, *T. Mod.*, 1892, p. 532). They each occur as colorless crystals, sparingly soluble in water, somewhat more soluble in alcohol. The acet-ortho-toluid is recommended in doses of 8 grains (0.5 Gm.); the acet-para-toluid in doses of 15 grains (1 Gm.).

Acetylene. C_2H_2.—Acetylene was first prepared by Berthelot, who obtained it by passing the electric spark between carbon points in an atmosphere of hydrogen. It is now prepared on a large scale by the decomposition of carbides, like calcium carbide, with water according to the reaction:

$$CaC_2 + 2H_2O = C_2H_2 + Ca(OH)_2.$$

The product so obtained is almost always contaminated with phosphine, and this should always be removed by washing the acetylene with bromine water. It is produced by a number of other methods involving the reduction of higher hydrocarbons and is produced to a limited extent when the flame of a Bunsen burner or gas stove strikes back and burns at the base, giving rise to its characteristic odor, by which the abnormal condition of the flame is frequently detected.

Acetylene is a colorless gas of ethereal odor, slightly soluble in water, more readily in alcohol and ether, and most abundantly in acetone. It burns ordinarily with a very smoky flame, but from a burner with a fine slit gives a clear white flame. It forms an explosive mixture with air, also a series of explosive compounds with copper, silver, and other metals. These compounds are in reality the carbides of the respective metals, the formula of the copper compound being Cu_2C_2.

According to Mosso and Ottolengui (*Rendiconti Della R. Academia dei Lincei.*, 1896) acetylene gas causes death through respiratory failure when more than 20 per cent. is present in the air, but Moissan (*C. R. A. S.*, cxxi) found that from 40 to 79 per cent. could be breathed without toxic manifestations while Oliver (*B. M. J.*, 1898, i) found it practically non-toxic if sufficient oxygen to maintain life was inhaled with it.

Calcium carbide, CaC_2, from which acetylene is made, is prepared by melting a mixture of powdered lime and coke dust in an electrical furnace. It is a grayish-brown, dense substance having a crystalline metallic fracture and the specific gravity of 2.26. It evolves a peculiar odor when exposed to the atmosphere, due to the action of moisture which causes partial decomposition with the production of acetylene. When exposed to the air, it decomposes and becomes coated with a layer of calcium hydroxide, which to a great extent protects the interior of the lumps from further deterioration. Calcium carbide is not inflammable and one pound, if pure, yields 5.9 cubic feet of acetylene gas at 18° C.

Acetylphenylhydrazin. $C_6H_5.(NH)_2C_2H_3O$.—This substance, first introduced into medicine in an impure form, under the name of *pyrodin*, has since been used in an alleged pure condition under the name of *hydracetin*. It is chemically closely allied to acetanilid, which possesses only one imido-group, (NH); it is, as indicated by its name, hydrazin in which hydrogen atoms are replaced by phenyl and acetyl. It forms colorless, inodorous crystals, melting at 128.5° C., soluble in fifty parts of water and readily soluble in alcohol. Guttmann (*Pr. M. W.*, 1889) demonstrated that this substance is a powerful antipyretic, in *doses* of from one and a half to two and a half grains (0.09–0.16 Gm.) but believes it to be a very dangerous remedy on account of its destructive action on the red-blood cells. Externally he considered it to be safe and allied to pyrogallic acid in its influence upon *skin diseases;* but Basch (*L. L.*, 1890) has seen very violent poisoning from the use of a 10 per cent. ointment, without benefit to the *psoriasis*. For fuller information see *U. S. D.*, 20th ed., p. 1226.

Achillea. *U. S.* 1870.—The flowering tops of *Achillea Millefolium* L. *Milfoil*, or *yarrow* is a perennial herb, very common both in Europe and America. It is from a foot to eighteen inches in height, and is specifically distinguished by its doubly pinnate, downy, minutely divided leaves, with linear, dentate, mucronate divisions, from which it derived the name of milfoil, by its furrowed stem and involucre, and by its dense corymbs of whitish flowers, which appear throughout the summer, from June to September. *Achillea nobilis*, L., and *A. moschata* Jacq., or *Iva* of Europe, are sometimes used as substitutes for *A. Millefolium*.

Both the flowers and leaves of *A. Millefolium* have an agreeable, though feeble, aromatic odor, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant contains volatile oil, tannin, and a peculiar principle, *achillein*, which was discovered by Zanon. (*Ann. Ch. Ph.*, lviii, 21.) As analyzed by von Planta (*Ann. Ch. Ph.*, clv, 1870) its formula is $C_{20}H_{38}N_2O_{15}$. It occurs in a brownish-red mass of a strongly bitter taste, soluble in water, more feebly in alcohol, and not at all in ether. *Achilleic acid*, also discovered by Zanon, is affirmed by Hlasiwetz to be identical with aconitic acid. The oil, which may be obtained separately by distillation with water, has a beautiful azure-blue color, and the peculiar flavor of milfoil. Schimmel & Co. (*B. Chem. G.*, 1894, p. 50) found its most important constituent to be cineol. The high boiling blue portion is probably identical with the *azulein* of chamomile oil. *Ivaïn*, $C_{24}H_{42}O_5$, has also been isolated; it occurs as a dark-yellow resinous mass, insoluble in water, readily soluble in alcohol, and producing an intensely bitter solution. There are a number of other species of achillea which have been distilled for the volatile oil, including *A. coronopifolia* Willd., *A. moschata* Jacq., *A. nobilis*, and *A. ageratum* L. The oils from these plants, while showing certain resemblances, vary greatly in physical properties. The specific gravity of the volatile oil has been variously reported as from 0.869 to 0.927.

Milfoil is a mild aromatic sudorific tonic and divided doses up to from thirty to seventy-five astringent. Pappi states that *achillein* given in grains (2–5 Gm.) causes marked irregularity of the pulse. The infusion is sometimes used in acute *suppression of the menses*. The *dose* of achillea is thirty to sixty grains (1.9–3.9 Gm.); the volatile oil has been used in doses of ten to fifteen minims (0.6–1.0 cc.).

Acocanthera.—The Wa Nyika, the Wa Gyriama, and the Wa Kamba tribes of Eastern Africa, and the natives of Obok on the Gulf of Aden, prepare vegetable arrow poisons probably from different species of plants, although the names *wabayo* and *ouabaïo* seem to have been used as synonyms by missionaries and others sending the extract to Europe.

The botanical sources of these arrow poisons are uncertain. It is certain that several species of the apocynaceous genus *Acocanthera* are used for arrow poisons by the natives of Africa. Of the four principal species, *A. Schimperi* B. and H. is found abundantly in the highlands of Abyssinia and throughout a great portion of Eastern Africa; *A. deflersii* Schwf., which resembles the last-named species closely, but, according to Schweinfurth, differs in that its flowers are larger, sweet-smelling and pure white, has been found in the neighborbood of Yemen; *A. ouabaïo* Arnaud is a native of Somaliland, and *A. venenata* Don. of South Africa. For details, see *A. de S.*, cvii, p. 1162; abs. in *J. P. C.*, 1889, p. 245. From *Acocanthera abyssinica* K. Shum. is prepared the *Shashi-poison* of German Eastern Africa.

In 1882 Arnaud obtained from an unidentified species of the genus *Acocanthera* (which he named provisionally *A. Ouabaïo*), a crystalline glucoside, and in 1893 Lewin separated from the *Acocanthera Deflersii* an amorphous glucoside.

Owing to the imperfect identification of the plants from which the principles have been obtained, there has been much confusion in the names which have been applied to the principles which various investigators have separated from these arrow poisons. According to Lewin (*B. K. W.*, 1906, p. 1583), there are two glucosides found in the various species of *Acocanthera*, one of which is crystalline, and the other amorphous. The amorphous substance, or, as it is generally known, *amorphous ouabain,* corresponds to the *abyssinin* of Briege (*A. I. P. T.*, 1903), and the *carissin* prepared by Bancroft from the *Carissa ovata* R. Br. (Fam. *Apocynaceæ*), an Australian plant. The *acocantherin* of Frazer he regards as identical with the crystalline ouabain of Arnaud, and probably is isomeric with the amorphous variety. It is generally conceded that the crystalline ouabain is chemically identical with the glucoside discovered by Thoms in the *Strophanthus gratus* (see *Strophanthus* Part I). Its action seems to be precisely the same as that of strophanthus. Ouabain was apparently first employed clinically by Stadelmann (*B. K. W.*, 1906, vol. xliii, p. 1586), and has since been used by others with more or less success in the treatment of various forms of *cardiac weakness.* Stadelmann used an amorphous glucoside prepared by Merck from the wood of the *Acocanthera Schimperi,* in *doses* of from one three-hundredth to one two-hundredth of a grain (0.0002–0.0003 Gm.) three times a day.

Crystalline oubain is used in the standardization of digitalis (see *Reagents*).

Acoine. 
$$\mathrm{HCl.C}\begin{matrix}\diagup\mathrm{NHC_6H_4O(CH_3)}\\ =\mathrm{NC_6H_4O(C_2H_5)}.\\ \diagdown\mathrm{NHC_6H_4O(CH_3)}\end{matrix}$$

Di-para-anisyl-mono-phenetyl-guanidine-hydrochloride. Guanicaine.—A white, crystalline powder, melting point 176° C., and soluble in water (six parts to one hundred). It is incompatible with iodine or alkaline iodides. Acoine was introduced as a local anesthetic by Trolldenier. (*Th. M.*, xiii; also *Zeit. T. M.*, 1901.) It has been specially used by ophthalmologists in a 1 per cent. aqueous solution, stronger solutions being very irritant or even corrosive. It is not absorbed through a normal conjunctiva, but when the epithelial covering is destroyed, or when the drug is injected into the sub-conjunctival tissues, it is said to act more powerfully than cocaine, and to be specially efficacious in the relief of deep-seated ocular pains. It is also actively antiseptic, the 1 per cent. solution remaining free from bacteria. Acoine has also been used with asserted excellent results in dentistry and in operations upon the nose. For dental purposes a 2 per cent. solution is preferred.

Acriflavine. *N. N. R.* 1924, *Acriflavine.*—Under the names of Proflavine and Trypaflavine have been introduced two derivatives of *diamino-acridine.* The *acridine* dyes are derivatives of a base found in coal tar,  $C_6H_4\langle{}^{CH}_{N}\rangle C_6H_4$. One of these derivatives—(diamino-methyl acridine chloride) $C_{14}H_{15}N_3Cl_2.H_2O$—was found by Ehrlich to possess valuable properties in trypanosome infections. He called it *trypaflavine.* English investigators later called it *acriflavine.* A closely related substance having similar properties is *proflavine.* Acriflavine is the hydrochloride of 3:6 diamino—10 methyl-acridine chloride $= C_{14}N_{14}N_3Cl.H_2O$. Proflavine is 3:6 diamino—acridine sulphate $= C_{13}H_{11}N_3H_2SO_4.H_2SO_4$. *Neutral Acriflavine* closely resembles acriflavine but is asserted to be less irritating.

These occur as reddish-brown powders, soluble in both water and alcohol, forming dark red solutions which fluoresce when diluted. Abelmann finds that a 1 per cent. solution of flavine is extremely sensitive to sunlight and in a short time turns brown and develops a fungus growth; it, however, keeps perfectly well in the dark. He states that the addition of an organic acid or of hydrogen dioxide produces a similar change to sunlight.

These dye-stuffs appear to be powerfully germicidal. According to Browning and Gulbransen (*Brit. Jour. of Exp. Path.*, 1921, ii, 95) acriflavine exercises a germicidal effect against the staphylococcus in as low a dilution as one in 200,000, although somewhat less powerful against the *B. coli.* There is considerable difference of opinion as to the real value of this compound. Its popularity in England is due largely to the work of Browning and his co-workers (*B. M. J.*, Jan. 29 and July 21, 1917) who assert that it rivals mercury bichloride in its disinfectant powers and against certain organisms, especially the staphylococci, is decidedly more germicidal. Further they assert that its disinfectant powers are enhanced by the presence of serum and that in appropriate concentrations it has no effect on phagocytosis. On the other hand Fleming (*L. L.*, September 1, 1917) finds that it is more injurious in its effects to leukocytes than to bacteria and that a 1 to 500 solution mixed with an equal quantity of pus failed to sterilize the latter within twenty-four hours. Carlslow and Templeton (*L. L.*, April 27, 1918) find that its action in wounds is antiseptic but not germicidal, but that in some way, despite the continuation of living bacteria in the wound, it lessens inflammatory reaction. Bashford, Hartley and Morrison (*B. M. J.*, 1918) state that although there is a marked lessening of suppuration and apparent preservation of the surrounding tissue under the influence of flavine, that it is decidedly inferior to the Carrel-Dakin treatment because it leads to slow epithelial growth and delays all the processes of repair. Flavine has been used as a disinfectant in the treatment of *gonorrhea* and as a surgical *wound* dressing. While many of the reports are favorable there is by no means unanimity as to their precise value (see *J. A. M. A.*, 1919, lxxiii, 1542). It may be used in strengths of 1 to 1,000. Davis (*Journ. Urology*, 1921, v, 215) recommends it by mouth in doses of 0.05 to 0.1 Gm. (three-fourths to one and one-half grains) as a urinary antiseptic in *cystitis,* and Buss has used (*D. M. W.*, 1923, xlix, 476) it intravenously in somewhat smaller doses in *epidemic encephalitis.*

Acrolein. *Acrylic Aldehyde. Allyl aldehyde.* $CH_2 = CH.CHO$.—Acrolein, a decomposition product of glycerin or glycerides, is a fluid which emits an intensely pungent odor, is soluble in two or three parts of water, and boils at 52.5° C. It is asserted by E. Koch and G. Fuchs (*Cb. B.*, 1899, xxvi) to be a valuable bactericide, but its exceedingly disagreeable odor and tendency to undergo decomposition have prevented its coming into use. It is the cause of the irritating vapors given off when glycerin or fats are heated in air to the point of decomposition.

Actæa. *Actœa spicata,* L. *Baneberry. Herb Christopher. Radix Christophorianœ. Racine de Saint Christophe,* Fr. *Christophswurz, Wolfswurz,* G.—This is a perennial herbaceous plant (Fam. *Ranunculaceœ*) growing in the woods of mountainous regions from Japan to Central Europe as well as in Siberia. Its dark-brown, bitterish, somewhat acrid root resembles that of *Helleborus niger,* for which it is said to be occasionally substituted. It is an active emeto-purgative, capable of producing, when in overdose, dangerous effects. There are two American species which probably have medicinal properties similar to those of *A. spicata*—namely, *A. alba* (L.) Mill., or *white cohosh*, and *A. rubra* (Ait.) Willd., or *red cohosh*, distinguished by the color of their berries. *Actæa racemosa* was the former name of the official *Cimicifuga racemosa.* (*Proc. A. Ph. A.*, 1858.)

Actinium.—This was discovered in 1899 in uranium pitch blend by De Bierne, a factory director in the radium plant of the Curies, and is asserted to be identical with the *anemium* of Giesel (De Bierne, *C. R. A. S.*, 1899, cxxix and 1904, cxxxix, p. 538). It is a radioactive element whose spectrum and atomic weight have not yet been definitely determined. It differs from radium in not being spontaneously luminous. Actinium gives out easily absorbable and penetrating deviable rays and a radioactive emanation which loses its activity in a few seconds. It has been used by Czerny and Caan (*M. M. W.*, 1911, p. 1801) in the treatment of various forms of *cancer.* They inject intramuscularly from one-sixth to two grains of actinium suspended in normal salt solution (0.01–0.12 Gm.).

It occurs commercially as a brownish-red powder, insoluble in water, but soluble in strong nitric or hydrochloric acids.

Actinomeris. *Verbesina helianthoides* Michx. (*Actinomeris helianthoides* Nutt.) (Fam. *Compositæ.*)—At one time known as *Gravel Weed, Diabetes Weed,* now known as *Sunflower Crownbeard.* It is a perennial herb growing in the thickets and on dry prairies from Ohio and Missouri to Texas and Georgia. The root was formerly used in Georgia in *dropsy* and *chronic cystitis. Dose* of infusion (one ounce to a pint), one fluidounce (30 cc.).

Adamon.—Adamon is the dibromo-dihydro cinnamic acid ester of borneol. It is used as a sedative in *neurasthenia, hysteria* and other conditions of nervous erethism. According to Oppenheim (*D. M. W.*, 1913, p. 1103), it is especially valuable as an anaphrodisiac in *nymphomania. Dose,* eight to twelve grains (0.5–0.7 Gm.).

Adansonia. *Adansonia digitata*, L. *Baobab.*—A tree of enormous magnitude, belonging to *Bombacaceæ.* It is a native of Africa, extending from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little odor or taste. By the Africans the leaves are used as a diaphoretic, and the subacid pulp of the fruit in *dysentery.* Under the name of *cream-of-tartar tree* various trees have been described. Their fruits contain, or have been supposed to contain, potassium bitartrate. The most important of these is the *Adansonia Gregorii* F. Muell., of North Australia. Another cream-of-tartar fruit is yielded by a tree of South Africa, which, according to E. M. Holmes, is probably the *A. madagascariensis* Baillon. E. J. Millard (*P. J.*, April, 1890), however, could find in this fruit no cream-of-tartar at all.

Heckel and Schlagdenhauffen (*Nouv. Rem.*, xxi, 487) have found in the fruit of the *Adansonia digitata* as much as 2 per cent. of free tartaric acid and 12 per cent. of potassium bitartrate. Duchassaing, of Guadeloupe, West Indies, and Pierre, of France commended the bark of *A. digitata* highly as an antiperiodic. (*A. G. M.*, 3e sér., xxiii, 535.)

Adenanthera. *Adenanthera pavonina* L. (Fam. *Leguminosæ.*) *Zangavara.*—Rochebrune (*Toxicologie Africaine*) obtained from this tree a crystalline principle which resembles in its activity physostigmine, but does not affect the muscles.

Adenia. *Adenia venenata* Troost.—A climbing passion-flower of Africa, said by Schweinfurth to be used as a vesicant. (*P. J.*, March, 1874.) The *Adenia hongkii* is employed by the natives of the Soudan as an ordeal poison. Perrott and LePrince (*P. J.*, 1910, lxxxiv, p. 82) have separated an active principle which is neither glucosidal nor alkaloidal, and which has a strophanthin-like effect.

Adhatoda. *Br. Add.* 1900. (Fam. *Acanthaceæ.*) —The fresh and dried leaves of *Adhatoda vasica* Nees. (*Justicia Adhatoda*, L.) The leaves are four to six inches long and about an inch and a half broad, lanceolate, entire short petiolate, taper-pointed, smooth on both sides. The dried leaves are of a dull brownish-green color which becomes much lighter when the leaves are powdered. They have a strong characteristic tea-like odor and a bitter taste. *Br. Add.*, 1900.

The leaves are stated to contain an alkaloid, *vasicine*, and an organic acid, *adhatodic acid* (see *Pharmacog. Indica*, vol. iii). Vasicine, isolated by Hooper, is soluble in water, sparingly in benzin and carbon disulphide, readily soluble in ether and chloroform. The claim is made for it that it exerts a powerful toxic influence upon lower forms of vegetable and animal life, and is not poisonous to the higher animals. The leaves are considerably used in India as an expectorant and antispasmodic, especially in the treatment of *asthma.* The Br. Add. recognized the *liquid extract* (*Extractum Adhatodæ Liquidum*, Br. Add., 1900), made with alcohol and given in *doses* of from twenty to sixty minims (1.3–3.75 cc.); the freshly *expressed juice* (*Succus Adhatodæ*, Br. Add., 1900), *dose*, from one to four fluidrachms (3.75–15.0 cc.); the *tincture* (*Tinctura Adhatodæ*, Br. Add., 1900), *dose*, from one-half to one fluidrachm (1.8–3.75 cc.).

Adiantum. *Maidenhair.*—Tradition has attributed to various species of this genus of ferns valuable properties in chronic pulmonic *catarrhs. A. pedatum*, L., of America, *A. Capillus-Veneris*, L., of Europe, *A. lunulatum* Burm., of India, are the most important species. The European species is sometimes employed on the Continent as an emmenagogue under the name of *polytrichi, polytrichon*, or *kalliphyllon*, and is given in the form of infusion, sweetened with sugar or honey, and a syrup prepared from it is said to be popular in France under the name of *sirop de capillaire,* and official in the French Codex.

Æsculus. *Horse-chestnut.*—The *Æsculus Hippocastanum*, L. (Fam. *Hippocastanaceæ*) seems to have been originally a native of Asia, but introduced about the middle of the sixteenth century into Europe, whence it has spread to this country. The seed or "nut" abounds in starch, but its bitter, disagreeable taste has prevented its general use as a food, although as long ago as 1856 starch was made from it in France, and recently a pleasant and nutritious article of diet is said to have been improved by removing its bitter principle by means of alcohol. For analysis of the oil it contains, see Stillesen, *Proc. A. Ph. A.*, 1909, lvii, p. 201. In the leaves Rochleder found *quercitrin*, and a bitter principle, *esculin* (*æsculin*); and in the capsules of the fruit a peculiar acid, *capsulæsic acid* (*J. P. C.*, May, 1859; Aug., 1860). (For Rochleder's method of extracting esculin, see *U. S. D.*, 18th ed.; for a second process, see *A. J. P.*, xliv, 400.) Esculin is in shining, white, prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol and in alkaline solutions. Its solution, which is fluorescent, is precipitated by lead subacetate, and its formula, according to Schiff, is $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$. When treated with dilute sulphuric acid, it is converted into grape sugar and a substance called *esculetin*, $C_9H_6O_4$, which is now known to be a dioxycoumarin.

Tannin is found in all parts of the tree, including the leaves as well as the bark and fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and ether; becomes red by the absorption of oxygen; colors ferric salts green, but violet on the addition of a little alkali; fluorescent when it is in alkaline solution; in concentrated solution is precipitated, at least partially, by sulphuric, hydrochloric, and metaphosphoric acids, but not by acetic acid, and forms also, with potassium and sodium sulphites and ammonium sulphide, precipitates which are readily dissolved by dilute acetic acid. (*J. P. C.*, Jan., 1868, 72.) Titherly and Coppin have found *allantoin* ($C_4H_6O_3N_4$) in growing shoots of the Horse-chestnut; *leucine* has been reported in the buds and *lecithin* in the seeds.

The powdered kernel of the nut is a sternutatory. The extract of the wood has been used in dyeing silk black. The fixed oil, extracted from the kernels by ether, has been employed in France as a topical remedy in *rheumatism;* and the bark as an antiperiodic in doses of half an ounce (16 Gm.) in the twenty-four hours, given in the form of decoction. The flowers are stated to contain quercitrin. In the United States a decoction of the leaves is popularly employed for *whooping cough*, and to the seeds themselves, when "carried in the pocket of the patient," is attributed the marvellous property of curing *hemorrhoids*, *rheumatism*, etc. Esculin has also been administered in *malarial disorders*, in fifteen-grain (1 Gm.) *doses* repeated once during the intermissions. (*Ann. Thér.*, 1859, 1860.) The glucoside esculin has the property, like other fluorescent substances, of absorbing ultra violet rays which are then gradually given off. Because of these properties, it is used on the one hand, as a protective against the effects of sunlight and on the other as a means of continuing the effect of heliotherapy. Thus Freund has found it useful not only against *sunburn*, but as a prophylactic against *snow blindness* (*Zeit. f. Neuere Physikal. Med.*, 1908, ii), and Graham (*L. L.*, 1905, ii, p. 1769) recommends it in the Finsen light treatment of *lupus vulgaris* and similar conditions. For this purpose he injected five minims (0.3 cc.) of a 2 or 3 per cent. solution immediately beneath the skin in the region to be treated by the light. Under the name of *zeozon* and *ultra-zeozon* there are upon the market pastes whose exact compositions are not stated but which are claimed to contain oxy-derivatives of esculin.

The fruit of the *Æsculus pavia* L., or *Red Buckeye* of the southern United States, is said to be an active convulsant. E. C. Batchelor (*A. J. P.*, xlv, 144) found in the cotyledons of the seeds about 2½ per cent. of a peculiar glucoside.

Æthusa. *Fool's Parsley. Æthusa Cynapium*, L. (Fam. *Umbelliferæ.*)—A fetid annual herb naturalized from Europe and growing in waste places or cultivated grounds in the northern United States and Canada.

The leaves of this plant are reported by Ewing and Clevenger to have been employed as an adulterant of *Conium maculatum* leaves (*Conii Folia*). They may be distinguished by their leaflets which in the case of *Æthusa* are rhomboid oval, deeply lobed, the segments sometimes further lobed, narrow to linear, blunt or abruptly pointed, whereas those of *Conium* are lanceolate-oblong, deeply incised with dentate, quite sharply pointed segments. (*J. A. Ph. A.*, 1919, viii, 385.) In 1859, Walz stated that the fruit of the *Æthusa Cynapium* contains a volatile base similar to coniine. This statement has been confirmed by Power and Tutin (*J. Am. C. S.*, 1905, xxvii) who recovered, besides various inert matters, about one forty-thousandth of 1 per cent. of the volatile alkaloid. This plant has been variously attributed with poisonous properties, but Harley (*P. J.*, 1880, xi, p. 43) denies any noxious quality, and, in the experiments of Power and Tutin, the extract from five hundred grammes of the dry herb caused, in a small dog, vomiting and salivation, but the animal entirely recovered.

Afridol. *Sodium hydroxymercuric toluylate. Mercuretol* $C_6H_3(CH_3)(COONa)HgOH$ 2:3:1.—This is an odorless, tasteless white powder, difficultly soluble in neutral or acid media, but soluble in ammoniacal solution containing ammonium chloride. It is said to be of value for rendering parts of the body antiseptic for surgical operations. It has also been recommended in the treatment of parasitic skin diseases, *acne*, *sycosis*, etc., the afridol soap being proposed for this purpose.

Agathin. $C_6H_5.N(CH_3).N:CH.C_6H_4.OH$. *Salicyl-a-methyl-phenyl-hydrazine. Salizone.*—This is obtained by the reaction of salicylic aldehyde upon *a*-methyl-phenyl-hydrazin. It is a yellowish crystalline substance, without odor or taste, is insoluble in water, soluble in alcohol and ether and melts at 74° C. It was proposed as a remedy by Israel Roos, and is said by E. Rosenbaum to act like salicylic acid. Although excellent results (see *D. M. Ztg.*, 1892, Nos. 50, 93) have been claimed for it in *neuralgia* and *rheumatism*, without unpleasant effects other than headache, in trials by H. C. Wood it did not seem serviceable. *Dose*, from five to ten grains (0.3–0.65 Gm.).

Agave. *Agave americana*, L. *American Agave. American Aloe. Maguey.* (Fam. *Amaryllidaceæ.*)—An evergreen succulent plant, indigenous to Florida, Mexico, and other parts of tropical America, and largely cultivated, chiefly for hedges, in the south of Europe, especially in Spain. Although the *Agave americana* is the best known form, botanists have described fifty species of the genus, which are indigenous to South America and the southern portions of North America, and many of which contribute to the economic products produced in that country from the agave plant. The number of these products is very great. *Sisal grass* or *sisal hemp* and *Tampico hemp*, also known as *Pita hemp* or *Pita fiber*, are the most important of the various fibers obtained from the agave leaves, though a number of other forms are locally known in Mexico. From a number of species of *Agave*, are produced in Mexico, large quantities of fermented liquors, known as *pulque*, and distilled liquors known as *mescal* or *tequila.* All of the pulque agaves have thick leaves. When they are about to bloom the central bud is cut out, leaving a large cavity into which the sap (*aguamiel* or *honey water*) exudes rapidly. At first clear green, yellowish or whitish, this sap soon by fermentation becomes milky and acquires a cider-like taste or, if the process is allowed to go on, is rapidly converted into vinegar. *Pulque* is said to contain about 7 per cent. of alcohol, and is very largely used as a beverage by the Mexicans, but its odor and taste are disagreeable to unaccustomed palates. The juice has in it an optically inactive reducing sugar, *agavose*, $C_{12}H_{22}O_{11}$. The leaves and roots and stocks of the agave contain saponin and are used in Mexico in the place of soap.

The fresh juice is said to be laxative, diuretic, and emmenagogue, and in doses of two fluidounces (60 c.c.) useful in *scurvy.* Under the name of *Matamel*, there has been placed upon the market a preparation, stated to be the concentrated fresh sap of the Agave, and intended for use in *nephritis* and other diseases of the genito-urinary organs. The leaves are said to be used as counter-irritants, and Lenoble has found in them an acrid volatile oil. (*J. P. C.*, xv.) *Agave Gum* has been compared to gum arabic, but differs in containing a much larger proportion of lime, and in being only partially soluble in water, the soluble portions resembling arabin, but the larger insoluble portions having all the characteristics of bassorin.

Agave virginica, L., which grows in our Southern States and is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used, in the form of tincture, in *colic.*

Agelæa. *Agelæa Lamarckii* Planch.—Under the name of *Cephan-Mahi, Soandrou, Vahé-mainti*, this African plant is used as an antiblenorrhagic. According to Rochebrune (*Toxicologie Africaine*), it contains a poisonous glucoside, *agelætoxine.*

Agrimonia. *Agrimonia Eupatoria*, L. *Common Agrimony. Herba Agrimoniæ. Aigremoine, Eupatoire des Grecs*, Fr. *Odermæning, Leberklette*, G. (Fam. *Rosaceæ.*)—This species of agrimony is a perennial herb, found in both Europe and North America. (Britton, however, maintains that the European species differs from any of ours.) A volatile oil may be obtained from the plant by distillation. Agrimony was at one time used as a folk-remedy in a wide variety of diseases but probably possesses no virtues except some astringent property. *Dose*, one drachm (3.9 Gm.) or more (see 16th ed., *U. S. D.*).

Ailanthus. *Ailanthus glandulosa* Desf. *Tree of Heaven. Chinese Sumach. Tree of the gods. Ailanto. Götterbaum*, G.—This well-known shade-tree, belonging to the Fam. *Simarubaceæ* in its general aspect and the character of its foliage, appears like a gigantic sumach, and was at one time considered to be a Rhus. In France it is cultivated for the sake of its leaves, upon which the Chinese silkworm is fed, and is known by the name of *Japan varnish* (*vernis de Japon*), from its having been mistaken for the true Japan varnish tree, which is a species of sumach. (*P. J.*, vii, 370.) The powdered bark is of a greenish-yellow color, possesses a strong, narcotic, nauseating odor, in the fresh condition, and has a strongly bitter taste. When chewed, it is said to produce a general uneasiness, a sense of increasing weakness, vertigo, cold sweats, with shivering and a sensation of nausea. F. H. Davis detected traces of a crystallizable organic acid, but no alkaloid or glucoside. (*A. J. P.*, 1885, 600.) By the action of alcohol, there is obtained from the bark an *oleo-resin* which has the consistence of tar, a very dark greenish-brown color, and in a high degree the odor and taste of the bark. Hetet found the bark to produce in dogs copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The powdered bark has been used successfully against the *tapeworm.* In China the bark is very popular as a remedy in *dysentery* and other *bowel complaints.* (*A. J. P.*, 1874, 276; *P. J.*, vii, 372.) *Dose*, from seven to thirty grains (0.5–2.0 Gm.).

In India the bark of the *Ailanthus excelsa* Roxb. is used as a bitter tonic. It occurs in rough, dirty-green pieces. Narayan Daji found in it a bitter uncrystallizable principle and a bitter nitrogenous acid, *ailanthic acid*, to which he attributes medicinal virtues. (*P. J.*, Aug., 1870, Oct., 1876, June, 1877.) This acid is not used medicinally in this country.

Air. *Liquid Air.*—This substance is produced commercially for the manufacture of oxygen and nitrogen. In its manufacture air is subjected to a pressure of 200 atmospheres, then cooled by a salt and ice mixture, and suddenly allowed to expand to 20 atmospheres. This compression and expansion is repeated until the temperature reaches –189° C., when most of the air liquefies. It is difficult to transport, owing to its tendency to vaporize, and is therefore usually used near the point of manufacture. It is usually a milky liquid, from the presence of solid carbon dioxide, but may be freed from CO_2 and becomes transparent and of a slightly bluish color. Substances such as rubber, meat, eggs, mercury, etc., when plunged into it are frozen solid in a few moments, becoming very brittle. When applied to the skin it freezes the parts and may be utilized as a local anesthetic for minor surgical operations. Taylor and McKenna (*L. L.*, 1909, ii, p. 1774) have used liquid air with good results in the treatment of *lupus erythematosus* and also for the destruction of *nævi.* The method of applying it is to wrap a piece of absorbent cotton around the end of a stick about ten inches long. This is immersed for a moment in liquid air and then pressed firmly against the part to be treated.

Ajowan. *Ajava. Ajwan.*—The ripe fruit of *Carum copticum* Benth. et Hook. (*Carum Ajowan* Benth. et Hook., *Ptychotis Ajowan* DC.), an annual of the Fam. *Umbelliferæ.* It is cultivated in India, Egypt, Persia and Afghanistan. The fruits resemble those of parsley, but are distinguished by their odor. They yield 3 to 4 per cent. of volatile oil which contains from 45 to 55 per cent. of thymol. This oil is official in the B. P. (see *Oleum Ajowan*). The fruits also contain from 25 to 32 per cent. of a fixed oil and from 15 to 17 per cent. of protein, making them a very good cattle food. They are used in the form of an extract and water, viz.: *Extractum Ptychotis Liquidum* P.I. and *Aqua Ptychotis* P.I. The water, known as *Omum water*, is used in India in the treatment of *cholera.* The *dose* of the *Fluidextract of ajowan* is ten to thirty minims (0.6–2.0 cc.).

Ajuga.—Of this genus *A. chamæpitys* L., or *Ground Pine; A. reptans*, L., *Mountain Bugle*, or *Common Bugle;* and *A. pyramidalis*, L., all of them European species, the last naturalized in America, have been used in medicine, and are probably mild astringents and tonics. The ground pine is said to contain a volatile oil, and has been used to some extent in *amenorrhea* and in various forms of *rheumatism*, in *doses* of from one to two drachms (3.9–7.7 Gm.). *Ajuga Iva,* L., of Sardinia, is said to be a depressomotor, an active bactericide, and an antiperiodic. (*A. I. B.*, xxxiv.)

Akazga. *Boundou. Quai. Ikaga. Icaya.*—An ordeal poison, largely used in a district on the west coast of Africa, extending far into the interior, north and south of the equator. The precise botanical character of the plant is unknown, but it is thought to belong to one of the *Loganiaceæ.* Thomas R. Fraser found in the plant an alkaloid, *akazgine.* The alcoholic extract or the alkaloid acts on the system similarly to nux vomica. (For further description, see *U. S. D.*, 19th ed., p. 1373 and also *A. J. P.*, March, 1867.)

Alangine.—This alkaloid, according to Scheriff, occurs in the bark of the stem and root of *Alangium Lamarckii* Thwaites (Fam. *Cornaceæ*), a shrub indigenous to the tropical forest of India and Burma. It is very bitter, soluble in alcohol, chloroform, and acetic ether, but insoluble in water. In small doses it acts as a febrifuge; in *doses* of fifty grains (3.2 Gm.) it is emetic.

Alanin (Alpha). $CH_3CH(NH_2)COOH$. *Propionic Glycocoll. Alpha-aminopropionic acid.*—Prepared from aldehyde ammonia by hydrocyanic and hydrochloric acid and forms white crystals that are soluble in alcohol and water. It is used as the basis for the preparation of alanin compounds.

Alanin Mercury (*Hydrargyri Amidopropionas. Mercury Amidopropionate*) has been used either internally or subcutaneously, in *doses* of from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.).

Alantol. (*Pinguin.*) $C_{10}H_{16}$.—Prepared by distillation from the root of *Inula Helenium* L. (*Elecampane*). It is a yellowish to a brownish-yellow liquid with a taste and odor similar to peppermint. It is insoluble in water and soluble in the immiscible solvents. It has been used in place of turpentine in *pulmonary tuberculosis. Dose,* one-sixth minim (0.01 cc.) 10 times daily.

Alchemilla. *Alchemilla vulgaris,* L. *Lady's Mantle.* (Fam. *Rosaceæ.*)—This astringent, bitter, perennial, European herb was formerly employed in *diarrhea.* By the ancients it was highly esteemed; extraordinary powers were ascribed to it by the alchemists. (*P. J.*, 1885, 791.)

Alcornoque.—For an account of this bark, which has long since fallen into entire neglect, see 16th ed., *U. S. D.*, p. 1545.

Aldehydes.—Aldehyde is a generic term that applies to a class of bodies holding an intermediate position between the alcohols and the acids derived from the former by oxidation. The word itself was coined from the Latin *alcohol dehydrogenatum,* meaning alcohol deprived of hydrogen. They are generally prepared by the oxidation, by chromic acid, of the respective alcohols.

Anisic Aldehyde. Anisaldehyde.—Prepared from anethol by oxidation. Formula $C_6H_4(O.CH_3).CHO$.—A colorless liquid with an aromatic odor. Soluble in alcohol and ether. Insoluble in water. Boiling point 248° C. Sp. gr. 1.126 at 15° C. It is used in admixture with other odorous substances in perfumery, the addition of other odors being necessary to bring out the agreeable hawthorn odor of the aldehyde.

Butylic Aldehyde. (*Iso-butyryl aldehyde.*) $(CH_3)_2CH.CHO$.—A transparent, colorless, highly refractive liquid. Boiling point 63°–64° C. Sp. gr. 0.797. Insoluble in water. Miscible with water and alcohol and possessing a pungent odor. Used in organic synthesis.

Ethyl Aldehyde. CH_3CHO. *Acetic Aldehyde. Ethylic Aldehyde. Aldehyde. Acetaldehyde. Aldéhyde acetique* (*vinique*), Fr.—This substance is commonly given the name "Aldehyde," which, being a generic name, is misleading and indefinite. The following formula for its preparation is given: One part of ethyl alcohol, of sp. gr. 0.842, and 1 part of potassium dichromate are introduced into a large tubulated retort, and 1⅓ parts of sulphuric acid dropped in through the tubulure. Sufficient heat is evolved to start the distillation, but heat must be applied towards the end. The distillate is slightly contaminated with acetic acid. If the aldehyde be desired pure, the distillate is to be mixed with twice its volume of ether, the vessel surrounded with cold water, and dry ammoniacal gas passed in to saturation. Aldehyde-ammonia crystallizes out. This is to be decomposed in a retort by a mixture of 3 parts of sulphuric acid and 4 parts of water, and the distillate rectified and dried by contact with calcium chloride. Aldehyde is a colorless, mobile, inflammable liquid, having a decidedly pungent, ethereal, and suffocating odor. Its sp. gr. is 0.790, and boiling point 22° C. It mixes in all proportions with water, alcohol, and ether, and is rapidly converted into acetic acid on exposure to the air, through absorption of oxygen. It possesses very marked antiputrescent properties, meat being preserved for months by its 2 per cent. aqueous solution. The intoxication caused by it in animals is characterized by a very great loss of sensibility. It appears to paralyze the vagi, although its cardiac action is comparatively feeble. Upon the respiration it exerts a most powerful influence, in small doses quickening it, in large doses depressing it. The temperature is much diminished. Applied locally aldehyde is very irritating. (*M. T. G.*, Sept., 1875.)

A condensation product of Ethyl aldehyde is known as "*Aldol,*" $CH_3CH(OH)CH_2CHO$, and is exploited as a hypnotic and sedative. It boils below 105° C. and is decomposed at 135° C. Like formaldehyde it will, on spontaneous evaporation, leave a solid polymeric residue, *Paradol.*

Heptoic Aldehyde. Oenanthol. Heptanal. $C_6H_{13}CHO$.—A highly refractive liquid, colorless and possessing an agreeable aromatic odor. It is prepared from castor oil by heating and fractional distillation, and is soluble in alcohol and ether and slightly in water. It is used in perfumery and as the basis of the preparation of other odorous aldehyde compounds.

Iodaldehyde may be made by mixing together iodine, iodic acid, and a solution of aldehyde and separating by adding water (see paper by P. Chautard, *P. J.*, 1886, 224).

Paracuminic Aldehyde. Cuminol. Cumyl Hydride. $(C_6H_4)(CH_3)_2.CH.CHO$.—A yellowish oily fluid with a persistent strong odor and an acid burning taste. It is one of the constituents of Roman chamomile. It is soluble in alcohol and ether and has a sp. gr. of .9382 at 0° C.

Propylic Aldehyde. Propionic Aldehyde. $CH_3CH_2.CHO$.—A colorless liquid with a suffocating odor, soluble in water, and boiling at 48° C. Sp. gr. 0.807. It is claimed to be a powerful antiseptic and an effective preservative. It is employed in organic synthesis.

Valeric Aldehyde. Isovaleric Aldehyde. $(CH_3)_2$-

$CH.CH_2.COCO$.—A colorless liquid with a pungent, apple-like odor. It is miscible in all proportions with alcohol and ether, boils at 92° C., and has a specific gravity of 0.804 at 15° C. It is used commercially as an artificial flavoring agent and in perfumery. It was also proposed at one time as a hypnotic and sedative, but was later on abandoned.

Alisma. *Alisma Plantago-aquatica,* L. *Water Plantain. Plantain d'eau. Pain de grenouilles,* Fr. *Froschlöffel, Wasserwegerich,* G. (Fam. *Alismaceæ.*)—A perennial herbaceous plant, common to Asia, Europe, and the United States. The root has, when fresh, an odor like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It contains a pungent volatile oil and an acrid resin, to which all its virtues must be ascribed. The Calmucks in Russia are said to use it for food. The leaves are rubefacient, and will sometimes even blister. They have been recommended in *gravel* and *cystitis. Dose,* a drachm (3.9 Gm.).

Alival. *Iod-dihydroxy-propane,* $CH_2.CH.OH.-CH_2OHI$.—This organic iodine compound occurs as odorless, white crystals, soluble in either water or alcohol, melting between 48° and 49° C. It is used for the effect of the iodine in the treatment of *syphilis* and other conditions, either by inunction or hypodermic injection.

Alkanet. *Alkanna Root, Alkanet Root, Orcanette,* Fr. *Spanish Bugloss. Alkannawurzel,* G.—This is the root of *Alkanna tinctoria* Tausch. or *dyers' alkanet,* an herbaceous perennial plant, of the Fam. *Boraginaceæ,* indigenous to Asia Minor and southeastern Europe. It is not to be confused with the allied bugloss formerly official (see *Anchusa*). (See E. M. Holmes, *P. J.*, 1897, p. 61. *Proc. A. Ph. A.*, 1896, 565.) Alkanet, as found in commerce, is in pieces 10 to 25 cm. long, and from 5 to 15 mm. thick, slightly twisted, one- to few-headed, consisting of a dark-red, easily separable bark, and an internal centrally placed ligneous portion which is reddish externally, whitish near the center, and composed of numerous distinct, slender, cohering fibers. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odor, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its coloring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a deep red color, but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of potassium or sodium carbonate, from which the coloring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue color, and soluble in alcohol and ether. Its weak acid character resembles that of alizarin, to which it is chemically related, as when distilled with zinc dust it yields methyl-anthracene. It has also received the names of *anchusin* and *alkannin.* The *anchusin* has been extracted and studied by C. J. S. Thompson. (*A. J. P.*, 1886, 409.) He finds it to vary in amount between 5.25 and 6.02 per cent. It is red, resin-like, insoluble in water, soluble in oils, alcohol, chloroform, and ether, and gives a rich deep blue color in alkali hydroxides, the color changing again to crimson on addition of an acid. According to A. Gawalowski, the red coloring matter of alkanet root consists of two distinct bodies, the one turning blue, the other green by the action of alkalies. The first of these, *alkannic acid,* is extracted by ether and alcohol. The second, *anchusic acid,* is obtained by extraction with benzene. Both form characteristic colored salts. (*Ph. Ztg.*, 1902, 817.) Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. The best way to use it with this object in view is to suspend the alkanet, after tying it in a piece of suitable fabric, in the melted fat. A fine color is obtained by previously washing the alkanet with water and then thoroughly drying it before suspending it in the fat or oil. It is said also to be used in the preparation of spurious *port wine.* The *Oleum Hypericum,* formerly much used under that title or the name *Red Oil,* consisted of fixed oil colored with alkanet.

Syrian Alkanet is the dried root of *Macrotomia cephalotes* DC., a perennial herb belonging to the same family and indigenous to the same regions as true Alkanet. It differs from true Alkanet in being many-headed, of much larger size, of black-violet color and metallic luster, more twisted and in having laterally placed wood. A similar coloring extract is present in Syrian Alkanet as is found in true Alkanet and in much larger amounts. (For details see Ewing and Clevinger, *J. A. Ph. A.*, 1918, 591–594.)

Allamanda.—*Allamanda cathartica,* L., is a shrub of the Fam. *Apocynaceæ,* growing in Porto Rico, the extract of whose bark is said to be an excellent hydragogue cathartic, in *doses* of from one to two grains (0.065–0.13 Gm.).

Alliaria. *Alliaria officinalis* Andrz. [*Sisymbrium Alliaria,* Scop. *Erysimum Alliaria,* L. *Alliaria Alliaria* (L.) Brit.] *Hedge Garlic.*—A perennial European herb, a native also of Northern Asia, and naturalized from Canada to Virginia, having an alliaceous odor when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its odor to the breath. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (*Ann. Ch. Ph.*, liii, 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and are used as external applications in *gangrenous affections,* and to promote *suppuration.*

Allocain.—In 1909 Professor Nagai of Japan prepared from the alkaloid ephedrine (see *Ephedra*) a synthetic substance which he called *Mydriatine,* which is chemically and physiologically related to epinephrine. By introducing into the molecule of this compound benzoyl and ethyl groups, he has prepared two synthetic substances which are actively local anesthetics; allocain S. contains one ethyl group and forms a soluble hydrochloride, while allocain A., containing two ethyl groups, forms an insoluble chloride.

The mono-ethyl-mydriatine hydrochloride, or allocain S., has been physiologically studied by Kubota (*J. P. Ex. T.*, 1919, xii, p. 361). It occurs as a white odorless crystalline powder freely soluble in either alcohol or water. Because allocain is very feebly basic, the salt has an acid reaction and is easily decomposed even by comparatively weak alkalies. It has a bitter, astringent taste. When applied to the tongue it produces a tingling sensation followed by numbness. He finds it possesses local anesthetic properties midway between those of procain and cocain, but that it is less toxic than either of these drugs. It has also some antiseptic powers.

Allonal.—Under this name has been introduced a sedative which is asserted to be a chemical combination of amidopyrine with *allyl-isopropyl-barbituric acid.* It occurs as a yellowish powder, slightly soluble in water, and represents 37.5 per cent. of allyl isopropyl barbituric acid and 52.5 per cent. of amidopyrine.

Allonal has been used by Burns (*N. Y. M. J.*, April 19, 1922) as an analgesic and hypnotic with marked success. He especially praises it for those cases in which there is *insomnia* caused by *pain.*

It is marketed in the form of tablets each of which represents 0.17 Gm. (2⅔ grains). One to three tablets may be given at a dose.

Allophanic Acid. *Acidum Allophanicum.* $NH_2.CO.NH.CO.OH$.—This is a *urea-carbonic acid,* but occurs only in the form of salts and esters, as at the moment of liberation the acid splits into urea and carbonic acid gas. Its best known derivative is its amide, called *biuret.* Apparently it exercises no influence on the system of itself, but according to Overlach (*B. K. W.*, 1908, p. 1403) is valuable because it has the power of forming compounds with a number of substances of unpleasant taste and penetrating odor, and rendering them much less disagreeable. For instance, santalol unites with allophanic acid to form a tasteless, dry, crystalline powder (having the composition $NH_2.CO.NH.COOC_{15}H_{23}$). The same is true of castor oil and of creosote.

Almatein.—This proprietary article is a condensation product of formaldehyde with hematoxylin and is given the formula $CH_2O_2.(C_{16}H_{12}O_5)_2.CH_2$. It is a bright red, light powder, odorless and tasteless, insoluble in water, but soluble in dilute alkalies, alcohol or glycerin. Astalfoni (*Press. Med.*, 1908) finds that it has a powerful antiseptic action and is non-poisonous. It passes through the system unchanged, and is split up by the alkaline intestinal juices, with the slow liberation of formaldehyde, and is employed as an intestinal disinfectant. It has been used also as a dusting powder on *wounds* (Werndorff, *M. M. W.*, 1909), also dissolved in glycerin as an injection in cold *abscesses.* One drawback to its use is its staining power. The *dose* for internal administration is from five to fifteen grains (0.3–0.9 Gm.).

Alnus. *Alder.*—Of this genus of small trees or bushes, *A. glutinosa* (L.) Medic., or *European Alder, Black Alder; A. rugosa* (Du Roi) K. Koch (*A. serrulata* Willd.), or *American Alder; A. incana* (L.) Willd., or *Speckled Alder,* are tonic and astringent, and have been used in intermittent fever, the bark being the part employed. *A. glutinosa* has been used for dyeing and also for tanning. According to Eitner, the bark contains from 16 to 20 per cent. of tannic acid which, according to F. Dreykorn and E. Reichardt, is resolved by sulphuric acid into *alnine red* and sugar. (*A. J. P.*, xlii, 403.)

Alpha-naphthol. $C_{10}H_7OH$.—This isomer of beta-naphthol is obtained in colorless prisms or powder of a disagreeable taste. It is sparingly soluble in water, but more soluble in alcohol and ether. It melts at 94° C., and boils at 278°–280° C. In antiseptic action it is about equivalent to its isomer, beta-naphthol. It is used internally as an antiferment in five-grain (0.3 Gm.) doses; in *typhoid fever* thirty to sixty grains (2–4 Gm.) a day. Externally it has been used in a 10 to 20 per cent. oily solution in *erysipelas, scarlet fever* and *smallpox,* as well as in various *skin diseases.* According to Maximovitch, alpha-naphthol has the same action upon pathogenic germs as has beta-naphthol, having the superiority over the latter compound, however, of being less poisonous to the higher animals in proportion to its germicidal power. It may be used in the same strength of solution and in the same dose as beta-naphthol.

The substance recommended as a germicide, under the name of *microcidin* is said to be a sodium-naphthol.

Alpha-naphthol has been proposed as a test for sugar in urine. Posner and Epenstein have studied the action of the test, and considered it to be free from many of the objections raised against other tests for sugar. The test depends upon the fact that a solution of sugar, in the presence of pure concentrated sulphuric acid and a solution of alpha-naphthol, gives a violet-colored reaction, due, according to Udransky, to the separation of furfurol. This reaction occurs not only with sugars, but with all carbohydrates and with certain albuminoids; hence *the urine must be free from albumin.* The test is said to be extremely sensitive, showing one-hundredth of one per cent. of sugar. The urine must always be previously diluted. *Winkler's test* for hydrochloric acid in the stomach is performed as follows: 5 Gm. of alpha-naphthol are dissolved in 100 cc. of alcohol, to which is added from 0.5 to 1.0 Gm. of grape sugar. A mixture of the filtered gastric juice is then evaporated with a few drops of the reagent in a porcelain dish on a water bath; if free hydrochloric acid be present, a bluish-violet marginal zone will appear and rapidly become inky black.

Alphol.—*Salicylic Ester of Alpha-naphthol, Alpha-naphthol salicylate,* $C_6H_4\left\{\begin{matrix}OH\\COOC_{10}H_7\end{matrix}\right.$, is obtained by reaction between salicylic acid and alpha-naphthol. It is a white, crystalline powder, melting at 83° C. Soluble in alcohol, ether, and fixed oils; insoluble in water, decomposed in the alkaline secretions of the intestinal tract into alpha-naphthol and salicylic acid. It is incompatible with alkalies and with ferric compounds. Used as an antiseptic and antirheumatic. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Alphozone. *Succinic Dioxide.* $(COOH.CH_2CH_2CO)_2O_2$.—This powerful oxidizing agent occurs as a fluffy, white, crystalline powder, the crystals being small, irregular plates. It is fairly soluble in water and alcohol, sparingly so in ether and insoluble in chloroform and benzene. It is devoid of odor and deteriorates slightly on exposure to air. It is employed for the germicidal and antiseptic properties of its nascent oxygen, being used both externally and internally. Unlike hydrogen peroxide it does not effervesce on contact with pus. It is employed in strengths of about 1 to 1000.

Aluminum.—(For description of chemical properties of aluminum, see *Alumen* Part I.) Under the name of *escalin,* a mixture of two parts of the finely powdered metallic aluminum with one part of glycerin has been employed by Klemperer (*Ther. Geg.*, May, 1907) as a substitute for the insoluble salts of bismuth, especially in the treatment of *gastric ulcers.* Sussman (*Ther. Geg.*, May, 1908) has also found this preparation useful in the treatment of *anal fissures.* It is marketed in the form of tablets, which when thrown into water disintegrate and yield on stirring a uniform suspension of the metal. Four of these tablets may be given at a dose, preferably on an empty stomach and repeated daily for three or four days.

Aluminum Acetate as well as the *subacetate* is largely employed in medicine. The deliquescent acetate may be made by the direct combination of hydrated alumina with acetic acid or by reaction between aluminum sulphate and lead acetate,

$$Al_2(SO_4)_3 + 3Pb(C_2H_3O_2)_2 = 3PbSO_4 + Al_2(C_2H_3O_2)_6.$$

The *neutral aluminum acetate* is a valuable astringent and antiseptic in *sore throat* and similar inflammatory conditions. It may be employed in the form of a gargle containing from 1 to 3 per cent. The relatively insoluble *basic acetate* is used as a dusting powder in *sweating feet,* in which it exercises both a desiccating and deodorizing influence, and in chronic *leg ulcers, weeping eczema,* and the like. A solution containing 7.5 to 8 per cent. of *basic aluminum acetate* is official in the N. F. under the title *Liquor Alumini Subacetatis,* which is practically identical with the *Liquor Aluminii Acetici* P. G. This must not be confused with the *Liquor Alumini Acetatis* N. F. or *Burow's Solution,* which is the solution of the neutral acetate also used for much the same purposes (see Part III). Stansburg (*Am. J. Surg.,* 1912, xxvi, p. 82) has found the N. F. solution of aluminum subacetate a valuable local application in *furunculosis, erysipelas* and *ivy poisoning.* He dilutes the solution with from seven to ten parts of water and saturates gauze with this solution and applies it over the diseased area.

Aluminum acetate is used for water-proofing fabrics such as clothing, tents, awnings, etc. A commercial solution of about 10 per cent. strength is diluted with about 40 parts of water. The fabric is completely immersed and after thorough saturation is removed and dried without washing. Metal buttons, fasteners, etc., should be removed before applying the treatment. Aluminum acetate is also used in embalming fluids, in textile dyeing and in the manufacture of lake colors.

Preparations asserted to contain the basic aluminum acetate have been introduced into therapeutics under the names of *lenicet* and *eston.* It seems probable, however, that the latter is a mixture of several aluminum salts (see Friedlander, *Ap. Ztg.,* 1907, p. 819). From eston is prepared two other compounds, one known as *formeston,* in which two of the acetyl radicals are replaced by formic acid, and the other *subeston,* which is a double basic acetate. These appear to be not only astringent, but also germicides of considerable power; Blasius (*Hyg. R.,* 1908, xviii, p. 941) finds that the saturated solution of eston, representing about 2 per cent. of the substance is fatal to most non-sporulating bacteria after thirty minutes' exposure.

Aluminum Acetico-tartrate. *Alsol.*—Under the name of alsol has been employed a 50 per cent. aqueous solution of the acetico-tartrate of aluminum. According to Aufrecht, this solution is a more powerful germicide than phenol. It has been found clinically valuable by Hanau and Pinner (*Med. Klin.,* 1909) wherever an antiseptic astringent is necessary, especially in the treatment of catarrhal conditions of the female genitalia. They applied it by means of gauze soaked in a 5 to 10 per cent. alsol solution. As a gargle or spray in *pharyngitis* and the like, it may be used in from 1 to 3 per cent. solution. A creamy solution of aluminum acetico-tartrate has been highly recommended by Lewitt (*Ther. Geg.,* 1910, p. 95) in the treatment of *pruritus, intertrigo, acne vulgaris,* and other skin diseases. A solution similar to alsol is recognized in the N. F. as *Liquor Alumini Acetico-tartratis* (see Part III).

Aluminum and Iron Sulphate. *Ferroso-Aluminic Sulphate. Sulphate of Aluminum and Iron.* $AlFe(SO_4)_2 + 12H_2O$.—This salt, which is prepared by the action of sulphuric acid on a mixture of recently precipitated aluminum oxide and ferrous carbonate, was formerly used as an internal astringent in chronic *dysentery* and *diarrhea* and externally in *relaxation of the uvula* and as a wash for foul and flabby *ulcers. Dose,* from five to ten grains (0.32–0.65 Gm.), dissolved in some aromatic water.

Aluminum and Potassium Salicylate. *Alkasal. Alkasol.*—It is prepared by the combination of aluminum salicylate and potassium acetate with the use of heat.

Alkasal-Athenstædt is the name of an aluminum potassium acetate. Both of these compounds are used for purposes similar to aluminum acetate.

Aluminum and Sodium Acetate. *Acetonal.* $Al_2(OH)_2.(C_2H_3O_2)_5Na$.—It is used as a 10 per cent. solution, and its equivalent can be prepared by dissolving 82 parts of sodium acetate in 4050 parts of liquor alumini acetatis *N. F.*

Aluminum Boroformate, $Al_2O_3B(OH)_3.H_2CO_2 + 5H_2O$, occurs in lustrous crystals, and may be prepared by introducing freshly precipitated alumina into a mixture of two parts of formic acid, one part of boric acid, and seven parts of water. The solution is evaporated and crystallized. Used as an antiseptic and astringent. (*Ph. Rund.,* 1894, 256.)

Aluminum Boro-tannate. *Cutol, Lutol.*—A brownish powder, insoluble in water, used as an astringent and disinfectant in diseases of the skin. It may be applied as an ointment or as a dusting powder.

Aluminum Boro-tartrate. *Boral.*—This is a crystalline substance, with a sweetish astringent taste, soluble in water. It is used, generally in powder form, as a local astringent in diseases of the nose and throat.

Aluminum Bromide. $Al_2Br_6.12H_2O$.—White or yellowish-white deliquescent crystals, soluble in water and alcohol. Used in organic synthesis.

Aluminum Carbide. Al_4C_3.—Greenish-gray pulverized masses. Sp. gr. 2.36. Used for generating methane extemporaneously.

Aluminum Carbonate. $Al_2(CO_3)_2$.—This occurs in chalky white, easily pulverized, tasteless lumps. It is used as a mild antiseptic astringent in *ocular affections, diarrhea,* etc. It is incompatible with acids, phosphates and lead acetate.

Aluminum Caseinate.—A yellowish-white, tasteless powder containing 5 per cent. of aluminum; insoluble in water, sparingly dissolved when macerated in saliva, and yielding aluminum to dilute acids. It was introduced by Rud. Meyer (*Ap. Ztg.,* Sept. 23, 1899, 566) as a remedy in *intestinal catarrh,* given in doses of four to five grains (0.26–0.32 Gm.). It is prepared as follows: Milk, freed from albumin, by repeated heating to 62° C. and straining, and then sterilized, is precipitated with solution of aluminum subacetate (*Liquor Alumini Subacetatis*); the precipitate is washed completely with water, and after removing the water with alcohol, deprived of fat by means of ether. The product is dried at a moderate temperature, and, while drying, powdered.

Aluminum Chlorate. $Al(ClO_3) + 6H_2O$.—Under the name of *prophylacticum mallebrein* there has been introduced a solution which is stated to contain 25 per cent. of aluminum chlorate. It is claimed to have the property of detoxicating bacterial toxins and hence to be useful in certain infectious diseases, notably *diphtheria* and laryngeal *tuberculosis.* It is applied either as a spray or gargle in strengths of from 0.5 to 1 per cent. See Jarosch (*D. M. W.*, 1912, p. 1979).

Aluminum Iodide. AlI_3.—Brown crystalline masses, soluble in water. Used in organic synthesis.

Aluminum Hydroxide. *Alumini Hydroxidum U. S. IX, Alumini Hydras* (*U. S.*, 1890), *Aluminum Hydrate, Hydrated Alumina; Argilla Pura,* s. *Hydrata; Hydrate de l'Alumine,* Fr.; *Thonerdehydrat,* G.—This salt, which was dismissed at the last revision of the *U. S.*, was defined in the *U. S. IX*, as: "A compound consisting principally of aluminum hydroxide $[Al(OH)_3 = 78.12]$." *U. S. IX.* The official process for its preparation was as follows:

"Alum, *one hundred grammes;* Monohydrated Sodium Carbonate, *forty-five grammes;* Water, *a sufficient quantity.*

"Dissolve each salt separately in *one thousand mils* of Water, filter the solutions and heat them to boiling. Then having poured the hot solution of Monohydrated Sodium Carbonate into a capacious vessel, gradually pour in the hot solution of Alum with constant stirring, and add *two thousand mils* of boiling Water. Allow the precipitate to subside, decant the clear liquid, and pour upon the precipitate *two thousand mils* of hot Water. Again decant, transfer the precipitate to a strainer, and wash it with hot Water, until the washings produce not more than a faint cloudiness with barium chloride T.S. Allow the precipitate to drain, dry it at a temperature not exceeding 40° C., and reduce it to a uniformly fine powder." *U. S. IX.* The alum solution is directed to be added to the sodium carbonate solution, because if the latter is not in excess during the whole period of precipitation a basic sulphate will be produced and contaminate the finished solution.

It was described as "a white, bulky, amorphous powder, odorless and tasteless; permanent in dry air. It is insoluble in water and alcohol; it is dissolved by hydrochloric or sulphuric acid and by the fixed alkali hydroxides. Solutions of Aluminum Hydroxide in hydrochloric or sulphuric acid yield with potassium hydroxide T.S. a white gelatinous precipitate, dissolved by an excess of the reagent but again precipitated by the addition of an excess of ammonium chloride. When heated to redness it loses about 34 per cent. of its weight. Boil 1 Gm. of Aluminum Hydroxide with 20 mils of distilled water, and filter the liquid; the filtrate does not show an alkaline reaction, and, on evaporation, does not leave a residue weighing more than 0.005 Gm. (*alkali salts*). Heat 1 Gm. of Aluminum Hydroxide with 10 mils of hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 50 mils of distilled water. Ten mils of this solution does not respond to the Test for heavy metals. Heat 1 Gm. of Aluminum Hydroxide with 5 mils of sulphuric acid and 5 mils of distilled water, on a water bath, for fifteen minutes. Then dilute it to 25 mils with distilled water and filter. Five mils of this filtrate meets the requirements of the Test for arsenic." *U. S.*

Aluminum hydroxide is feebly astringent and probably slightly antiseptic. It is used chiefly as a protective and astringent application either in the form of an ointment or suspension, or as a dusting powder in the treatment of various inflammatory *skin diseases.*

Aluminum Lactate.—Perutz (*M. M. W.*, 1913, p. 1261) has used solutions of aluminum lactate in strengths of from 0.1 to 2 per cent. for its astringent effect in *chronic gonorrhea, eczema, mercurial ptyalism,* etc. He was unable to demonstrate any direct antiseptic effect, but found that in suppurative conditions it exercises a beneficial influence. Under the trade name of *Fixin* a proprietary form of this salt has been suggested as a gastro-intestinal disinfectant. Another preparation of aluminum lactate is known as *algal* and is intended as a local astringent. The advantages claimed for this preparation by Kionka (*B. K. W.*, Feb. 25, 1922, 408) are that it has less irritating effect than other preparations of aluminum.

Aluminum Oleate. $Al_2(C_{18}H_{33}O_2)_6$.—A white to a yellowish tenacious mass, soluble in alcohol and ether, and is used as an antiseptic in skin diseases. It is used as a water-proofing compound, and as a dryer in the paint industry. Wiechowski (*M. M. W.*, 1921) has recommended it as a dusting powder and also as a substitute for lead plaster.

Aluminum Phenolsulphonate. *Sozal. Aluminum sulphocarbolate.* $Al_2(C_6H_4HSO_4)_6$.—This forms a reddish-white powder of slight phenol odor and astringent taste. It is soluble in water and alcohol. Merck recommends it as a substitute for iodoform, especially commendable in *cystitis* and suppurating *ulcers.* (*Ph. Ztg.*, 1892.)

Aluminum Salicylate. *Salumin.* $Al(C_6H_4OH\text{-}COO)_3$.—A reddish-white powder, insoluble in water and alcohol, but soluble in dilute alkalies. It is employed in nasal and throat affections by insufflation. *Ammoniated aluminum salicylate,* a yellowish, water-soluble powder, is also used in the same manner, and in solution is employed in *catarrh* and *ozena,* as a spray.

Aluminum-sodium Sulphate. *Sodium Aluminum Sulphate. Soda Alum, S. A. S.,* $Al_2Na_2(SO_4)_4 24H_2O$.—Colorless transparent crystals soluble in water. Used in the textile and paper industry for making dry colors, in water purification and as an ingredient in so-called "alum" baking powders.

Aluminum Subformate. *Aluminum formate.* $Al(HCOO)_2OH$.—Under the name of *alformin,* a solution containing about 16 per cent. of aluminum subformate has been used as an astringent and disinfectant. In *pharyngitis,* five to ten drops of this solution may be added to a glass of water and used as a gargle.

Aluminum Subgallate. *Gallal.* $Al_4(C_7H_2O_5)_3 + 4H_2O$.—Basic aluminum gallate is an amorphous, brownish powder prepared from solutions of alum and sodium gallate. It is insoluble in water, but soluble in diluted acids. It is employed, chiefly in *ozena,* as an antiseptic astringent.

Aluminum Tannotartrate.—Yellowish-white lamellæ or powder, strongly astringent taste, soluble in two parts water. It has been employed as an insufflation or gargle in rhinolaryngological and other catarrhal affections. It is incompatible with iron compounds, phosphates and alkalies.

Alumnol. *Aluminum Beta-naphthol-disulphonate.* $Al_2(C_{10}H_5(OH)(SO_3)_2)_3$. *Alumini Naphthol-sulphonas, N. N. R.* 1924.—A whitish, nonhygroscopic powder darkening slightly on exposure to air, easily soluble in cold water and very soluble in glycerin, slightly soluble in alcohol. Its aqueous solution has a slight bluish fluorescence, feeble acid reaction, and is colored blue by iron chloride. The solution of 40 per cent. is made with hot water and remains clear on cooling. Though it coagulates albumin, it is said to be dissolved in an excess of albumin, and, therefore, to be able to reach deep recesses of wounds.

It has been strongly recommended as an astringent and antiseptic in nasal, urethral, and other catarrhal inflammations. The strength of the solution employed varies from 1 per cent. in *gonorrhea* to 10 per cent. in *abscesses.* (See *B. K. W.*, 1892; *Th. M.*, 1892, 644.) Two to ten parts of alumnol mixed with ten parts of starch has been used by insufflation in cases of *laryngitis.* Alumnol, however, would appear to be very feeble and slowly acting as a germicide, a 1 per cent. solution requiring twenty-four hours to destroy bacilli of anthrax. As a surgical dressing from 1 to 2 per cent. solution may be used. In *infected wounds* the caustic 20 per cent. solution is employed. In diseases of the skin alumnol is used with talc or starch as a powder, or with lanolin as an ointment, the strength varying from 2 to 20 per cent. Its solutions are incompatible with caustic alkalies and alkaline carbonates, with albumen, gelatin solutions, soluble nitrates, silver salts, and other reducible salts. Rubbed with phenol it produces a plastic mass.

Alundum.—A technical name for an artificial form of *aluminum oxide,* Al_2O_3 Made by fusing bauxite in an electric furnace. Used in making porous chemical filters and other apparatus, and as a refractory and an abrasive.

Alypin. *Benzopropyl. Amydricaine. N. N. R.* 1924. $CH_3.CH.C(C_6H_5COO).CH_2N(CH_3)_2.CH_2N(CH_3)_2$. Alypin is 2-benzoxy-2-dimethyl-amino-methyl-l-dimethyl-amino-butane-hydrochloride. It bears a close relation to *Stovaine,* which see. It occurs as a crystalline hygroscopic powder, freely soluble in both water and alcohol, with a melting point of 169° C. Its solution will stand boiling for a period of five minutes. The *nitrate* of this same base has been also introduced, especially for the purpose of using in combination with silver salts.

Alypin has been employed as a substitute for cocaine in the production of surgical anesthesia either by local application or injecting into the subarachnoid space. It differs from cocaine in that it produces relaxation of the blood vessels, when applied locally, instead of constriction. According to Le Brocq (*B. M. J.*, March 27, 1909), alypin is about equally anesthetic to cocaine but is more highly toxic. Sollmann finds (*J. A. M. A.*, 1918, lxx, p. 216) that alypin, when injected into the nerve trunk, is about half as efficient as cocaine and, when applied over mucous membranes about one-fourth as efficient. Several cases of alypin poisoning have been reported of which at least two have ended fatally. The symptoms have been cyanosis, convulsions, stupor and arrest of respiration (see Lichtenstein, *Ther. Geg.*, 1914, xvi). Braun (*D. M. W.*, 1905) reports that it produces pronounced irritation at the point of injection, and this view has been confirmed by other investigators, especially as regards its ophthalmic use. As a local anesthetic it would, therefore, appear to have no advantages over the other preparations of its class. It has also been employed in doses of one-sixth to one-third of a grain (0.01–0.02 Gm.) for the relief of *vomiting.* As a local anesthetic it may be used in strengths of from 2 to 5 per cent. and its solutions in these strengths are stable but become moldy when further diluted. An alkali hydroxide or carbonate gives a precipitate with an aqueous solution of alypin; mixed with calomel and dampened with alcohol alypin gives a black color.

Amapa Milk.—The milky sap of the bitter bark of *Plumeria fallax* Muell. (Fam. *Apocynaceæ*), a Brazilian tree, has been recommended as a vermifuge and antimalarial, having been used and known by the natives of Brazil and South America from time immemorial. It is also used externally in the treatment of *cancerous sores. Dose,* for children, one minim for each year of age.

Amber. *Succinum. Ambre, Succin,* Fr. *Bernstein,* G.—Amber is a fossil resin, occurring generally in small detached masses in alluvial deposits, in different parts of the world. According to Goefert, there are about fifty species of extinct coniferous trees of which amber represents the resinous exudation. It is found chiefly in East Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface. Large deposits occur in some lakes on the eastern coast of Courland, and an extensive bed of yellow amber was discovered in 1854, on sinking a well in the coal mines near Prague. The largest mass of amber yet found weighed thirteen pounds. Amber also occurs in considerable quantities near Catania, in Sicily. It is usually associated with lignite, and sometimes encloses insects and parts of plant tissues. In the United States, it was found at Cape Sable, Maryland, by Troost. In this locality it is associated with lignite and iron pyrites. It has also been discovered in the greensand formation of Martha's Vineyard, at Harrisonville, N. J., and elsewhere. The amber consumed in this country is brought from the ports of the Baltic. A deposit of it is said to have been discovered near Rockwood in Australia.

It is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its color is generally brownish-yellow, either light or deep, but is occasionally reddish-brown or bluish from staining with ferric phosphate. It has no taste, and is inodorous when cold, but exhales a peculiar, aromatic odor when heated. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1.07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 286.7° C., swells, and at last inflames, leaving, after combustion, a small amount of ash. Subjected to distillation it yields first a yellow acid liquor, which is a solution of impure *Succinic Acid,* then a thin yellowish oil together with a yellow, waxy substance which is deposited in the neck of the retort. This waxy substance yields the *chrysen* of Laurent and the *idrialin* of Dumas, both of which are hydrocarbons. (Pelletier and Walter, *J. P. C.*, v, 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape. By continuing the heat, the oil gradually deepens in color, until towards the end of the distillation, it becomes black and of the consistence of pitch.

Tschirch (*Harze und Harzbehälter*) finds the main constituents to be a *Succinoabietic ester of borneol*, which is extracted by prolonged treatment with alcohol, and amounts to 30 per cent. of the amber, and the *succinic ester of succinoresinol*, which is insoluble in alcohol and makes up 70 per cent. of the amber. This latter compound contains a small amount of sulphur (about 0.47 per cent.).

Amber was held in high estimation by the ancients as a medicine, but at present is never so used. The credulous sometimes employ an amber necklace to keep away infantile ills. The *oil of amber* is an empyreumatic product which is prepared by destructive distillation of amber. The heat requisite for the complete decomposition of amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire; sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-colored liquid, of a peculiar, strong, empyreumatic odor. In this state it is occasionally employed as a liniment, but for internal use it should be rectified.

By successive distillations oil of amber becomes thinner and more limpid, till at length, it is obtained colorless. Under the name of *Oleum Succini Rectificatum* the U. S. P. of 1870 recognized the oil of amber purified by redistillation with water. For practical purposes, however, the oil is sufficiently pure when once redistilled. As first distilled it has an amber color, sp. gr. 0.903 at 15.6° C., and a boiling point from 170.5°–186.1° C. (Ebert.) When quite pure it is said to be colorless, as fluid as alcohol, of the sp. gr. 0.758 at 23.8° C., and to boil at 85.5° C. It has a strong, peculiar, unpleasant odor, and a hot acrid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in five parts of 90 per cent. alcohol and in all proportions in absolute alcohol, ether, chloroform, carbon disulphide, and the fixed oils. (Ebert.) It appears to be a hydrocarbon of the terpene class. It was officially described as "a colorless or pale yellow, thin liquid, becoming darker and thicker by age and exposure to air, having an empyreumatic, balsamic odor, a warm, acrid taste, and a neutral or faintly acid reaction. Sp. gr. about 0.920. It is readily soluble in alcohol. When mixed with fuming nitric acid, it acquires a red color, and, after some time, is almost wholly converted into a brown, resinous mass of a peculiar musk-like odor." *U. S.*, 1870.

Rectified oil of amber was employed in *amenorrhea, hysteria,* and *whooping cough.* The *dose* is from five to fifteen minims (0.3–0.9 cc.), diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient.

Ambergris. *Ambra Grisea (cinerea). Ambre, Ambre gris,* Fr. *Amber, Graue Ambra,* G.—This substance, which is found floating on the sea, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus* L., or *sperm whale.* It is in roundish or amorphous pieces, usually small, but sometimes weighing as much as 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. Ambergris is of various colors, usually gray, with brownish, yellow, and white streaks, often dark brown or blackish on the external surface. It is opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odor, is almost tasteless, softens with the warmth of the hand, melts under 100° C., is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein.* When pure this has little or no odor. Beauregard and Gouchet believe that ambergris is a calculus composed of crystals of *ambrene* mixed with black pigment and star-coral débris.

When fresh ambergris is disagreeable in odor. If kept for a year or two in air tight containers it loses its excrementitious odor and acquires the characteristic perfume for which it is valued, although its use in perfumery is more for the purpose of fixing delicate floral odors than for any odor which it contributes to the mixture itself. This change Beauregard believes is due to a microbe (*Spirillum recti physeteris*). (*C. R. A. S.*, cxxv, 254.)

Ambergris was formerly regarded as a cordial and antispasmodic, somewhat analogous to musk, useful in *typhoid fevers,* and various nervous diseases. It is no longer used as a medicament but is employed in perfumery. It is comparatively rare and very expensive, the black variety commanding a price of from $10 to $15 an ounce, while the white or gray variety costs in the neighborhood of twice that figure. *Dose,* five grains to a drachm (0.32–3.9 Gm.)

Ambrine.—The trade name for a French proprietary preparation which has been on the market for many years, but has come into prominence because of its large use during the European war in the treatment of *burns.* Similar preparations are on the market sold under the trade names *ambryl, cerambine, mulene, parresine, thermozine, hyperthermine,* etc. It is essentially solid paraffin with the addition of ingredients which increase its adhesiveness and plasticity. According to Leech, a similar preparation may be made by dissolving 5 drops of asphalt (*asphalt varnish* or *B. asphaltum*) in 1.5 cc. of olive oil with the aid of heat, and incorporating the solution with 97.5 Gm. of melted paraffin (melting point 47.2° C.). (*J. A. M. A.*, lxviii, p. 1498.) A number of other formulas have been proposed, among them paraffin, 96 per cent., and yellow wax, 4 per cent. The essential factor seems to be a melting point between 38° and 53° C., a sterile product, sufficient strength to the film so that it may readily be lifted from the burn and a pliability which will prevent breaking if bent. In applying it to the burn the melted mixture is sprayed or painted over the area, to form a thin layer, absorbent cotton is then applied and afterwards more of the melted mixture. (Sollmann, *J. A. M. A.*, 1917, lxviii, p. 1037 and 1799.)

Ambrosia. *Ambrosia trifida* L. *Ragweed, Roman Wormwood, Hog-weed, Bitter-weed, Ambrosie,* Fr. *Traubenkraut,* G. (Fam. *Compositæ.*)—This and another indigenous annual, *A. artemisiæfolia* L., are deemed by the eclectics astringent and stimulant, and are given in low forms of *fever.*

L. W. Schwab has found in *A. artemisiæfolia* a bitter glucoside (*A. J. P.*, 1890), and Schimmel & Co. have obtained from it about 0.15 per cent. of a green volatile oil (sp. gr. 0.876). (*Schim. Rep.*, 1904, p. 96) The pollen of this plant is one of the causes of hay fever. Sutton (*J. A. M. A.*, 1919, lxxiii, p. 1433) claims that in susceptible persons the ragweed pollen may give rise not only to hay fever but also to dermatitis which may or may not be accompanied with symptoms of nasal irritation. He reports several such cases of dermatitis. It is estimated that there are about 90,000,000 pollen grains in a gramme of ragweed pollen.

Amenyl.—Amenyl is the hydrochloride of *methylhydrastimide.* It occurs as yellowish needles, melting at 227° C., soluble in hot water and alcohol. Amenyl has been used by Falk (*Th. M.*, 1909, p. 581) in the treatment of *amenorrhea.* The *dose* is one grain (0.065 Gm.).

Amidophenols. *Derivatives of p-amidophenol,* $C_6H_4(OH)NH_2$.—In an elaborate series of experiments (*Cb. I. M.*, 1897) Treupel and Hinsberg find that derivatives from amidophenol are active as antipyretics in proportion as they are decomposed in the system, and that the decomposition is to be measured by the amount of indophenol in the urine. Among these substances is *dulcin,* called also *para-phenetolcarbamide* and *sucrol,*

$$CO\begin{cases}NH.C_6H_4.OC_2H_5\\NH_2\end{cases}$$

which occurs in white, glittering, needle-like crystals, melting at from 173°–174° C., soluble in 800 parts of cold and 55 of boiling water, and 25 of alcohol, having a taste which is said to be two hundred times sweeter than sugar. (Dulcitol, the carbohydric alcohol related to gelatose, is sometimes assigned the name of "dulcin," and should not be confused with the amidophenol "dulcin" which possesses distinctly different characteristics.) It has been recommended as a substitute for sugar, in *diabetes,* and, on account of its solubility, to improve the flavor of castor, cod liver, or other oils. According to Treupel and Hinsberg, fifteen grains (1 Gm.) of it will reduce the temperature in fever about one degree Centigrade in the course of about three hours, and no unaltered dulcin is to be found in the urine, but indophenol.

Besides dulcin, Treupel and Hinsberg examined physiologically the following amidophenol derivatives: *Lactylamidophenolethylcarbonate, benzoylacetamidophenol, ethyldiacetamidophenol, oxyphenacetinsalicylate.*

The use of dulcin, saccharin and other artificial sweetening agents as substitutes for cane sugar is prohibited by most food laws.

Ammi. *Ammi visnaga* Lam.—The fruit of this umbelliferous plant, indigenous in the countries around the Mediterranean, contains a crystalline principle, *kellin* (*C. R. A. S.*, August, 1879), which is said (*Union Méd.*, April, 1886) to act upon the heart and spinal cord. Mild antipyretic and antilithic properties have been attributed to the fruit.

Ammonium Arsenate. *Ammonii Arsenas.* $(NH_4)_2HAsO_4$.—This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or ammonium carbonate, and allowing it to evaporate spontaneously. The crystals, which belong to the trimetric system, effloresce on exposure to the air, and lose half their ammonia. Its solution is alkaline. It has been used with advantage by Biett in several inveterate *diseases of the skin.* It is administered in solution, one grain of the salt in a fluidounce of distilled water; twenty to twenty-five minims (1.2–1.6 cc.) of this solution may be given in divided portions in the course of the day.

The *ammonium arsenite,* NH_4HAsO_2, a water-soluble, white powder, has also been used after the manner of and for the same purposes as the arsenate.

Ammonium Bicarbonate. *Acid Carbonate of Ammonium.* $H(NH_4)CO_3$.—This salt was brought into notice by Wm. Procter, because of its antacid properties. It is formed by exposure of the ordinary carbonate to the air, and is found in considerable quantities on the sides of casks in which that salt is imported, and less largely even in the bottles in which it is kept in commerce. For further information concerning this salt, see *U. S. D.*, 19th ed.

It is a commercial article occurring as white crystals, sp. gr. 1.59, soluble in water, fairly stable. Used in the manufacture of ammonium salts.

Ammonium Binoxalate. *Acid Ammonium Oxalate.* $NH_4H_2CO_4 + H_2O$.—Colorless trimetric crystals soluble in water and used solely for removing ink stains from fabrics, and ecchymotic spots from the face.

Ammonium Bisulphite. NH_4HSO_3.—White crystals soluble in water and used internally in fermentative *dyspepsia* in ten to thiry grain (0.66–2.0 Gm.) doses and externally as a wash in *sore mouth* and *skin affections.* The *bisulphate,* NH_4HSO_4, colorless water-soluble crystals, has been given in fifteen to sixty grain (0.9–3.9 Gm.) doses in *gastric affections.*

Ammonium Borate. *Ammonium Metaborate.* $(NH_4HB_4O_7) + 3H_2O$.—Only the acid salt is known. By dissolving one part of boric acid in excess, in three parts of heated water of ammonia, sp. gr. 0.960, and allowing the solution to cool slowly, this salt is obtained in crystals. These are rhombic octahedrons, with truncated summits, and often truncated edges, and are semitransparent. The taste of the salt is alkaline, and it has an alkaline reaction. On exposure, it effloresces, losing ammonia, and becoming in time the tetraborate. It is soluble in about twelve parts of water. It is believed by Becker to be the *ludus* of Paracelsus, which had a great reputation in the treatment of *urinary calculi. Dose,* ten to twenty grains (0.65–1.3 Gm.) every hour, in water sweetened with licorice. (*Journ. de Thérap. Méd.-Chir.*, Sept. 1, 1866.)

Ammonium Carbamate. *Ammonium Carbaminate.* $NH_4HCO_3NH_4CO_2$.—A white crystalline powder, exceedingly volatile. It is the anhydride of ammonium carbonate and is used in the manufacture of the latter substance.

Ammonium Camphorate. *Ammonium Bicamphorate.* $NH_4HC_{10}H_{14}O_4 + 3H_2O$.—A white, crystalline powder soluble in water and possessing a sedative action on the nervous system. *Dose,* one to three grains (0.06–0.18 Gm.).

Ammonium Cuprate. Made by precipitation of copper hydroxide from solution of cupric sulphate by molecular proportions of sodium hydroxide solution and the subsequent dissolving of this precipitate in strong ammonia water. Also known as *ammoniated copper oxide* and *cuoxam* used as a cellulose solvent and in waterproofing fabrics.

Ammonium Iodide.—*Ammonii Iodidum,* U. S. IX. *Iodohydrate d'ammoniaque,* Fr. Cod.

This salt has been dismissed from the U. S. P. For process of making it see *U. S. D.,* 20th ed., p. 135. It was officially described as: "minute, colorless, cubical crystals, or as a white, granular powder, odorless and having a sharp saline taste. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to air and light, owing to the loss of ammonia and the liberation of iodine. One Gm. of Ammonium Iodide dissolves in 0.6 mil of water, 3.7 mils of alcohol and in 1.5 mils of glycerin at 25° C.; also in 0.5 mil of boiling water. When strongly heated, Ammonium Iodide evolves vapor of iodine, and volatilizes without fusing, leaving not more than 0.1 per cent. of residue. An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus. When heated with potassium hydroxide T.S. ammonia is liberated. Add a few drops of ferric chloride T.S. to 5 mils of an aqueous solution of the salt (1 in 20); iodine is liberated which imparts a violet color to chloroform when shaken with the solution. Ten mils of an aqueous solution of Ammonium Iodide (1 in 20), when acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*). Ten mils of an aqueous solution of the salt (1 in 150) does not at once assume a blue color upon the addition of 3 drops of potassium ferrocyanide T.S. (*iron*). Shake 5 mils of an aqueous solution of the salt (1 in 150) with 1 mil of chloroform; no violet color is imparted to the latter (*free iodine*). An aqueous solution of Ammonium Iodide does not respond to the Test for heavy metals (see Part III, Test No. 3).

"*Assay.*—Proceed as directed under the Assay for iodides, using about 0.5 Gm. of Ammonium Iodide, previously dried to constant weight at 100° C. and accurately weighed in a stoppered weighing-bottle. It shows, in the dried salt, not less than 99 per cent. of NH_4I. Each mil of tenth-normal silver nitrate V.S. corresponds to 0.014496 Gm. of NH_4I. Each gramme of Ammonium Iodide, previously dried, corresponds to not less than 68.3 mils nor more than 70.1 mils of tenth-normal silver nitrate V.S." *U. S. IX.*

Its most serious disadvantage was its instability and the loss of ammonium and liberation of iodine unless most carefully preserved.

Ammonium iodide is employed, both externally and internally, as a resolvent, and does not differ perceptibly from the other iodides (see *Iodum*). It is used in *secondary syphilis, chronic rheumatism,* and in *scrofulous disorders* attended with glandular enlargements. It has been especially recommended in *chronic bronchitis* with fibrinous exudate and in *asthma,* with the thought of combining the resolvent action of the iodide to the expectorant effect of ammonium. Pennock used it in cases of *lepra* and *psoriasis,* in the form of ointment, applied by friction in the quantity of half an ounce, morning and evening. The proportions employed ranged from 4 per cent., in recent cases, to 12 per cent. in the chronic conditions. As the iodide is decomposed by the air, the ointment should be kept in well-stoppered bottles.

Dose, three to ten grains (0.20–0.65 Gm.).

Ammonium Nitrate. *Ammonii Nitras. U. S.* 1890. *Nitrate of Ammonia.* NH_4NO_3.—Ammonium nitrate may be prepared by treating commercial ammonium carbonate with nitric acid so long as effervescence takes place, or to saturation, filtering, and evaporating the solution. It is usually obtained as a by-product in the manufacture of other chemicals.

"Colorless crystals, generally in the form of long, thin, rhombic prisms, or in fused masses, without odor, having a sharp, bitter taste, and somewhat deliquescent. Soluble, at 15° C. in 0.5 part of water, and in 20 parts of alcohol; very soluble in boiling water, and in 3 parts of boiling alcohol. When gradually heated, it melts at 165°–166° C.; at a temperature between 230° and 250° C. it is decomposed into nitrogen monoxide gas and water, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and when gently heated with potassium or sodium hydrate test-solution, it evolves the odor of ammonia. On heating the salt with sulphuric acid, it emits nitrous vapors." *U. S.,* 1890.

For further information concerning this salt, see *U. S. D.,* 19th ed., p. 1380.

It is used in the manufacture of nitrogen monoxide and of pyrotechnics and explosives.

For the mode of preparing nitrogen monoxide from ammonium nitrate, see *Nitrogenii Monoxidium.*

Ammonium Persulphate, $(NH_4)_2S_2O_8$, is prepared by electrolyzing an acid solution of ammonium sulphate, and is a most efficient oxidizing agent in acid, neutral, or alkaline solutions. It occurs in small, colorless crystals, soluble in water. Its solution evolves oxygen when heated, and is used as an antiseptic and as a cheap and effective mouth wash. Ammonium persulphate is used in photography and in electroplating, and also as a reagent. In medicine it is chiefly valuable as forming the basis of *Klett's test* (*Chem. Ztg.,* 1900, p. 690) for indican in urine. To 10 cc. (160 minims) of urine add 5 cc. (80 minims) of 25 per cent. hydrochloric acid together with a crystal of ammonium persulphate, to which add chloroform and agitate, when a blue color develops in the latter.

Ammonium Phosphomolybdate. $2(NH_4)_3PO_4.24MoO_3.12H_2O$.—A yellow crystalline powder soluble in water and alkaline solutions, used as a reagent for alkaloids.

Ammonium Phosphotungstate. *Ammonium phosphowolframate* $2(NH_4)_3PO_4.24WO_3. + H_2O$.—A white powder soluble in water and alkaline solutions, used as a reagent for alkaloids.

Ammonium Sulphate. *Ammonii Sulphas. U. S.* 1880. $(NH_4)_2SO_4$; 131.21 *Sal Ammonium Secretum Glauberi. Sulfate d'Ammoniaque, Sel secret de Glauber,* Fr. *Schwefelsaures Ammoniak,* G.—Gas liquor is distilled with lime and the gas received in sulphuric acid, which yields a purified product. Most of the ammoniacal liquor is worked up into ammonium sulphate at present. In the United States the production of ammonium sulphate has increased enormously in recent years, owing to the introduction of by-product coke ovens. "Colorless, transparent, rhombic prisms, permanent in the air, odorless, having a sharp, saline taste and a neutral reaction. Soluble in 1.3 parts of water at 15° C. and in 1 part of boiling water; insoluble in absolute alcohol, but slightly soluble in alcohol of sp. gr. 0.817; when heated to about 140° C., the salt fuses, is gradually decomposed, and on ignition is wholly dissipated. The aqueous solution of the salt, when heated with potassa, evolves vapor of ammonia. With test-solution of chloride of barium it yields a white precipitate insoluble in hydrochloric acid. A 1 per cent. solution of the salt should not be blackened by test-solution of sulphide of ammonium (lead and iron), nor, when acidulated with nitric acid, should it be rendered more than opalescent by test-solution of nitrate of silver (limit of chloride)." *U. S.*, 1880. It is not used as a medicine, but enters into the composition of ammonium alum and the iron and ammonium sulphate, and is the principal source of ammonia gas used in chemical manufacturing, refrigeration, etc.

Ammonium Tartrate.—The neutral ammonium tartrate has been used by Clausen for the clearing up of *corneal opacities.* The eye is irrigated with a warm neutralized solution containing 5 per cent. of ammonium tartrate for twenty to thirty minutes two or three times a day.

Ammonium Uranate. *Ammonii Uranas.* $NH_4U_2O_7 + (H_2O)_n$.—This is a reddish-yellow, amorphous powder, insoluble in the usual solvents. It has been used by Weil (*S. M.*, 1907, p. 573) with asserted favorable results in the treatment of *syphilis.* The remedy was administered in doses of five-sixth grain (0.5 Gm.), suspended in a liquid petrolatum, by intra-muscular injection. The strength of the suspension was 5 per cent. and the injections were made once a week. The treatment required on an average of two months. It is used in the arts for painting on porcelain.

Ammonium Urate. *Ammonii Uras.* $C_5H_3(NH_4)N_4O_3$.—This is an acid salt, and may be formed by digesting uric acid in solution of ammonia, or by adding sal ammoniac to the solution of other urates. Ammonium urate is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano. It has been used with asserted good effects externally in chronic *eczema,* in the form of an ointment (twenty grains to the ounce). (See 16th edition, *U. S. D.*)

Amygdophenin. *Phenetidin Amygdalate.* $C_6H_4.OC_2H_5NH.CO.CH.OH.C_6H_5$. *Phenyl-glycol-phenetidin.*—This is a derivative of *p*-amidophenol, analogous to phenacetin. It is a light, crystalline, grayish-white powder, soluble with difficulty in water. It is obtained by the action of mandelic acid upon *p*-phenetidin in the presence of dehydrating agents. R. Stüve asserts that it is practically free from antipyretic properties; that it is an analgesic which is often useful in *neuralgias* and the pains of *spinal scleroses;* and that it is very useful in *rheumatism,* it having had more effect in some comparative trials than the salicylates. It is best administered in capsules, fifteen grains (1 Gm.), from three to six times a day.

Amyl Alcohol. *Alcohol Amylicum,* $C_5H_{11}OH$. *Isobutylic Alcohol, Isobutylcarbinol. Fousel Oil. Fusel Oil. Hydrate of Amyl. Grain Oil. Potato Spirit Oil. Alcool Amylique, Huile de Grain,* Fr. *Fuselöl,* G.—This alcohol is always present in the products of alcoholic fermentation—particularly when starchy materials are the starting point—and, according to the experiments of L. Perdrix (*J. Chem. S.*, 1892, 90), the bacillus *B. amylozymicus* produces a fermentation in starch resulting in a large production of amyl alcohol. It is an ingredient in the ardent spirit obtained from various grains, but is most abundant in that procured from fermented potatoes. In grain spirit it is present in the proportion of about one part in five hundred by measure. When grain or potato whisky is distilled for the purpose of obtaining alcohol, the pure spirit will continue to come over for a certain time, after which, if the distillation be continued, a milky liquid will be obtained, which, upon standing, will be covered with a stratum of amyl alcohol. Subjected to distillation, the milky liquid will at first boil at a comparatively low temperature, and yield water and a little of the alcohol; but after a time the boiling point will rise to 132° C. when the amyl alcohol will come over pure, and by changing the receiver may be so collected.

Amyl alcohol is an oily, colorless liquid, of a strong, characteristic odor, and an acrid, burning taste. As usually prepared it has a pale yellow color. Its sp. gr. is about 0.810; that of its vapor 3.15. It boils at about 130° C. and congeals at −25° C. in the form of crystalline leaves. It is sparingly soluble in water, but mixes in all proportions with alcohol, ether, and essential oils. It dissolves iodine, sulphur, and phosphorus, and is a good solvent for fats, resins, camphor, and alkaloids. When dropped upon paper it does not leave a permanent greasy stain. It does not take fire like alcohol by the contact of flame, but requires to be heated to a temperature of about 54.5° C. before it begins to burn. Pasteur first observed that the ordinary amyl alcohol of fermentation was a mixture of two distinct alcohols, one present in smaller amount, optically active, levogyrate, and the other, the main portion, optically inactive. Their boiling points are very close, but they may be separated by the difference in solubility of the barium amyl-sulphates, and yield different sets of derivatives. (*C. R. A. S.*, xli, 296.) Heated with phosphoric acid, it loses a molecule of water, and forms a hydrocarbon, C_5H_{10}, homologous with ethylene, called *amylene* or *valerene,* which has been proposed as an anesthetic. According to Long and Linebarger, American fusel oil consists chiefly of active and inactive amyl alcohol, with some isobutyl alcohol, isopropyl and ethyl alcohols, and traces of normal propyl and normal butyl alcohols. (*Chem. News,* lxi, 185–187.) Amyl alcohol should not affect the color of litmus paper, previously moistened with water, should leave no fixed residue upon evaporation, should require to dissolve it about 40 parts of distilled water at 15° C., and should become not more than slightly turbid upon mixture with petroleum benzin (absence of more than a little alcohol, or water). (See *Amylene* below.) When subjected to oxidizing agents, it loses two atoms of hydrogen and gains one of oxygen, and becomes $C_5H_{10}O_2$, or *valeric acid,* the acid found in valerian. Hence the test given in the Br. Pharmacopœia of 1885: "Exposed to the air in contact with platinum-black, it is slowly oxidized, yielding valerianic (valeric) acid." The free amyl, $(C_5H_{11})_2$, has been isolated by E. Frankland. It is a colorless transparent liquid, of the sp. gr. 0.7704. Its hydride, $C_5H_{11}H$, possesses anesthetic powers.

A mixture of amyl alcohol, green soap, phenol (1 per cent.) and water, under the trade name of *Amyl Karbol,* has a wide use in Europe as a disinfecting solution.

Crude fusel oil is found in commerce as a by-product of the distillation and rectification of ethyl alcohol made from grain. Kent, of New York, found in it, as impurities, water, alcohol,

UNIVERSITY OF ILLINOIS LIBRARY CHEMISTRY

acetic and valeric acids, oxide of iron, and an amyl compound analogous to *œnanthic ether*. Fusel oil has been used largely by the manufacturers of alkaloids as a solvent and in the preparation of *amyl acetate* (*pear oil, banana oil*), which is used in the manufacture of pyroxylin varnishes and smokeless powder and as a basis for the manufacture of isoprene, lately used in the manufacture of synthetic caoutchouc. This manufacture of amyl acetate for solvent purposes now consumes the great bulk of the fusel oil obtained from the rectifiers.

Fusel oil was formerly recognized by both the United States and the British Pharmacopœias as a source of artificial valeric acid.

Amyl alcohol is an active narcotic, and under the name of *Faints* (*feints*) a strong solution of the substance which is obtained as a by-product in the manufacture of whiskey, is used in England and Northern Europe for the purpose of increasing the activity and prolonging the effects of ordinary liquors. In small doses it is said to be efficacious in controlling the nervous weakness and irritability of confirmed drunkards, while larger doses produce headache, giddiness, double vision, staggering, unconsciousness, fall of temperature, abolition of reflexes, muscular rigidity, followed by complete relaxation, pronounced cyanosis, and a peculiar odor from the breath suggesting that of a Jargonelle pear.

Horand has employed amyl alcohol for its disinfecting and desiccating action in inoperable *cancerous ulcers*. (*R. T.*, 1910.) He asserts that by the local application of from three to ten drops daily there is not only a disappearance of the odors, but often a shrinking in the size of the tumor, and considerable improvement in the general condition.

T. B. Futcher (*Am. Med.*, August, 1901, p. 210) has shown that both in animals and also in man, when taken in toxic doses, fusel oil affects profoundly the blood, causing methemoglobinuria, also glycosuria, attended with the presence of combined glycuronic acid, and in some cases violent nephritis. The size of the fatal dose probably varies very much. It is affirmed that death occurred from the taking of a single fluidounce (30 cc.), but in another case recovery resulted after six fluidounces (180 cc.) had been swallowed.

Amyl Butyrate. *Iso-amylbutyric ester*, $C_4H_7O_2$-C_5H_{11}.—A colorless liquid with pleasant characteristic odor, sp. gr. 0.859, boiling point 154° C. Soluble in alcohol and ether, almost insoluble in water. Used in flavoring and in organic synthesis.

Amyl Formate. *Iso-amyl formate*, $CH_2OC_5H_{11}$.—Colorless, fragrant liquid, sp. gr. 0.902, boiling point 130° C. Soluble in alcohol and ether. Almost insoluble in water. Used in artificial flavoring compounds.

Amyl Salicylate. *Salicylic Amylester. Amylenol.*

$$C_6H_4\left\langle\begin{matrix}OH\\CO_2C_5H_{11}\end{matrix}\right.$$

A colorless or yellowish refractive fluid, possessing an odor resembling that of salol, having the sp. gr. 1.065 at 15° C. Sp. gr. 1.045, boiling point 268°–273° C. It is slightly dextrorotatory. Refractive index (20°) 1.505–1.507. The preparation dissolves in ether, alcohol, and chloroform, but it is almost insoluble in water. This substance has been proposed by B. Lyonnet (*R. T.*, lxviii, No. 2) as a substitute in *rheumatism* for methyl salicylate, over which it has the advantage of less pronounced odor and taste. It is also coming into wide use as a fixing agent for delicate odors in perfumery. As a medicine it is given internally usually in gelatin capsules, three to five minims (0.2–0.3 cc.) each, eight or ten times a day. It has also been found useful as a local application, one-half to one drachm (2.0–3.9 Gm.), being applied to rheumatic joints and covered with wax paper, or other impervious dressing. It is incompatible with acids or acid salts and with iron compounds.

Amyl Valerate. *N. N. R.* 1924. $C_4H_9COOC_5H_4$.—The isovaleric acid ester of iso-amyl alcohol. A colorless liquid having, when diluted with alcohol, in which it is very soluble, an odor of apples. Insoluble in water, sp. gr. 0.881; boiling point 203°. It has been used in the place of valerian in the treatment of various nervous conditions.

Pouchet asserts that amyl valerate (*J. des Pr.*, 1899, 45) has the power of softening, or if present in sufficient quantity, of dissolving cholesterin, and recommends its use in the treatment of *gall-stones*. *Dose*, three to eight minims (0.2–0.5 cc.). It has been used as an artificial apple flavor.

Amylene. *Valerene. Pentene. Pental. Beta-iso-amylene. Tri-methyl-ethylene.* $(CH_3)_2C.CH.$-CH_3.—This name is given to the isomeric hydrocarbons of the olefin series, having the formula C_5H_{10}, of which five are possible. Amylene is prepared by distilling amyl alcohol with a concentrated solution of zinc chloride, which acts by dehydrating, withdrawing a molecule of water. The product is redistilled, and that which comes over first, constituting the more volatile part, is separately collected, and agitated with concentrated sulphuric acid, when the amylene, freed from water, will rise to the surface. Amylene is a colorless, very mobile liquid, having the density 0.666 at 10° C. Its boiling point is 37°–42° C. Its odor is peculiar and disagreeable. It is soluble in alcohol and ether in all proportions, but very sparingly so in water. When pure it does not act on potassium, and is not colored by a prolonged contact with potassium hydroxide. It undergoes polymerization very readily.

In 1857, Snow, of London, proposed amylene as an anesthetic. It was highly commended by W. Lombardino. H. C. Wood and David Cerna have, however, shown that pental acts upon the lower animals as a powerful cardiac depressant, and clinical experience has demonstrated that it is too dangerous for practical use.

Amylene Hydroxide. Amylene Hydrate. Tertiary Amyl Alcohol. Dimethylethylcarbinol ($C_5H_{12}O$ or $(CH_3)_2C.(C_2H_5)OH$) is a clear, colorless liquid, of a strong, penetrating odor, soluble in eight parts of water, and miscible with alcohol, ether, chloroform, petroleum benzin, glycerin, and fixed oils in almost all proportions; sp. gr. 0.814 at 12° C.; boiling point 102° C.

In 1887, von Mering proposed the use of amylene hydroxide as a soporific, stating that it stood midway between hydrated chloral and paraldehyde in power. In cases of poisoning, reported by C. Dietz, by the amylene hydroxide, the symptoms were deep narcosis, dilated pupils, loss of corneal reflexes, slow, deep, irregular breathing, small, slow pulse, and fall of temperature. According to Brackmann, confirmed by W. Niessen, it is valuable in *diabetes insipidus*, lessening thirst and polyuria. Amylene hydrate has also been recommended for the relief of *epileptic* and *eclamptic* *convulsions.* It is also used in artificial fruit flavors and in organic synthesis. *Dose,* fifteen minims (0.9 cc.) morning and evening.

Pentane.—Amyl hydride, $CH_3CH_2CH_2CH_2CH_3$, was discovered by E. Frankland of Manchester. It is a saturated hydrocarbon, and has been proved to be one of the light products in American petroleum, being the portion boiling at from 37°–39° C. (Schorlemmer). Amyl hydride is a colorless, volatile, mobile liquid, possessing a fruity odor, and having no taste. It is one of the lightest liquids known, having the sp. gr. 0.626 at 17° C. It boils at 38° C., and the sp. gr. of its vapor is 2.5. It is very inflammable, and burns with a brilliant white flame. It is readily soluble in alcohol and ether, but insoluble in water. Belonging to the paraffin or saturated series of hydrocarbons, it is a very stable compound, resisting the action of fuming sulphuric acid and the most powerful oxidizing agents. This substance was proposed by Simpson as an anesthetic, but has not sustained the claims made for it. It is used as a solvent in analytical chemistry and as an illuminant in photometric determinations. It is also used for filling low-temperature thermometers and as a lubricant in liquid air machines.

Amylene Carbamate.—Under the name *aponal* amylene carbamate $C(CH_3)_2C_2H_5.COONH_2$ has been introduced as a somnifacient. It seems to be a drug of only moderate power but acting promptly and apparently without injurious after-effects. The *dose* is from eight to thirty grains (0.5–2 Gm.).

Amyloform.—*Formamylum* is a patented chemical compound of formaldehyde and starch, introduced by Claassen as a substitute for iodoform. It is stated to be odorless, innocuous, and nonirritant. *Dextroform* is a similar compound, in which dextrin is used in place of starch. Dextroform is soluble in water and glycerin. Amyloform can be heated to 180° C. without decomposition, and therefore is readily sterilized. It is said to be non-poisonous, and has been used by Langgard, Krabbel, and others as a dusting powder in the treatment of infected *ulcers* and wounds of all kinds. It is said to act more energetically in lessening secretion and as a disinfectant than iodoform.

Amylzyme.—"An extract containing all of the digestive enzymes of the fresh pancreas of the hog." *N. N. R.*, 1924. It occurs as a pale yellowish powder, somewhat hygroscopic and only partially soluble in water with a neutral or slightly acid reaction. Although it possesses the proteolytic and fat-splitting actions of the pancreatic secretions, its power is estimated by its action upon starch. It is stated to digest 110 times its weight of starch in ten minutes. It is used like pancreatin for its enzyme action especially in *starchy indigestion.*

Amytin.—The ammonium salt of a mixture of sulphonated hydrocarbons prepared by the action of sulphuric acid on various hydrocarbons and subsequent treatment with ammonia. Under the name of amytin (*anytin, anysin*), Unna has introduced into medicine a 33 per cent. aqueous solution of *ichthyol-sulphonic acid,* which has the property of dissolving ichthyol, various ethereal oils, phenol, and camphor, forming solutions which are known by Unna as *Amytoles* (*anytoles*). Amytin is more or less irritant to the skin, and is affirmed to be useful in those skin diseases which need stimulation.

Anacardium. *Anacardium occidentale* L. *West Indian Cashew-nut. Acajou à Pommes,* Fr. *Caschunuss,* G.—A small and elegant tree of the Fam. *Anacardiaceæ,* growing in the West Indies and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. Peckoldt describes *cashew gum* as occurring in hard, fragile pieces which are more or less transparent, yellowish-brown, and stalactite-shaped, and is as soluble in water as acacia. (*Zeit. Oest. Apoth. Ver.*, 1893, 501.) The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-colored, kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of a pericarp having large balsam canals and of a sweet oily kernel which is now an article of commerce as a food, sold either in the raw state or roasted and salted. The receptacle is red or yellow, and of agreeable subacid flavor with some astringency. It is edible, and affords a juice which has been recommended in *uterine complaints* and *dropsy.* This juice is converted by fermentation into a vinous liquor, which yields by distillation a spirit used in making punch, and said to be powerfully diuretic.

Although the pericarp contains a very acrid oil, the seeds are edible. The black juice contained between the outer and inner shell of the nuts is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. Staedeler found in it two peculiar principles—*anacardic acid* and a yellow, oleaginous liquid, *cardol* ($C_2.H_{30}O_2$). (See *J. P. C.*, 3e sér., xiii, 459.) At one time it was sometimes applied to the face by women, in order to remove the cuticle, and produce a fresher and more youthful aspect. The juice, or its active oil, has been used in medicine for a discutient. In the West Indies the juice is said to be employed for the removal of *corns* and *warts* and in the treatment of *ringworm* and *elephantiasis.* The oil of cashew-nut hulls has been employed in the treatment of *leprosy.* It is brown in color and has a sp. gr. of 0.9868, a saponification number of 123, and an iodine number of 163. (See *Proc. Penna. Pharm. Asso.*, 1918, xli, 167). The fumes of the roasting nuts have caused violent dermatitis, the exposed parts becoming red and enormously swollen, and very painful. The tincture of iodine has been found useful as a local application. The black juice of the nut and a milky juice which flows from the tree after incision are used for almost indelibly marking linen.

Ammonium Anacardolé has been used as a hair dye. The *Oriental Cashew-nut* or *Anacardium Orientale* is the fruit of *Semecarpus Anacardium,* L., a tree quite common in Southern Asia. It contains principles similar to the West Indian Cashew, and is also said to contain an alkaloid, *chuchunine.*

Anagallis. *Anagallis arvensis,* L. *Scarlet Pimpernel. Red Chickweed. Weather-glass. Mouron rouge,* Fr. *Gauchheil, Rothe Miere,* G. (Fam. *Primulaceæ.*)—An annual plant, growing in Europe and the United States. It has little odor, but a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and Orfila found three drachms of its extract to cause fatal gastroenteritis in a dog. It has been recommended as a local application to old and ill-conditioned *ulcers,* and has been used as a folk-remedy in *visceral* *obstructions, consumption, dropsy,* etc. J. A. Heintzelman obtained from it a volatile oil of a strong, peculiar odor, a pungent and somewhat acrid taste, and the sp. gr. 0.987. Four drops (0.25 cc.) of it produced intense headache and nausea, lasting for twenty-four hours, with pains throughout the body. According to Daccomo and Tommasoli, anagallis contains an active ferment, which rapidly digests raw meat (*Rassegna di Sci. Med.*, 1892, No. 4). *A. cœrulea* (Schreb.) Ledeb., having blue petals, is a variety of *A. arvensis,* and shares its medicinal properties.

Anagyris. *Anagyris fœtida,* L. (Fam. *Leguminosæ.*)—Hardy and Gallois have separated from *Anagyris fœtida* an alkaloid, *anagyrine.* Parthiel and Spasski found that the crude alkaloid could be separated into *cytisine,* $C_{11}H_{14}N_2O$ and *anagyrine,* $C_{15}H_{22}N_2O$; the latter is not obtainable in crystalline form; it forms a brittle, resinous-like mass easily reducible to a yellowish powder, but rapidly absorbs moisture and becomes sticky. It volatilizes at 245° C. (*A. Pharm.*, 1906, ccxliv, 20.) It forms, however, a crystalline hydrobromide.

Anagyrine hydrobromide, which has the formula $C_{14}H_{18}N_2O_2HBr$, occurs in colorless or faintly yellow crystals soluble in water. Anagyrine, according to Loewi (*A. I. P. T.*, vol. vii, p. 66), is physiologically related to lobeline, acting primarily upon the nerve endings as a paralyzant and later upon nerve centers, but having no direct influence upon the muscles. It lessens the cardiac frequency and decreases the force of the systole in the frog, but is said in the mammal to have very little influence upon the blood-pressure, death occurring through respiratory paralysis.

Analgen. *Ortho-ethoxy-monobenzoyl-amidoquinoline. Benzanalgene. Quinalgene. Labordin.* $C_{18}H_{16}N_2O_2$. $C_9H_5.(OC_2H_5)NH(CO.C_6H_5)N$.—The name analgen was first given to the acetyl derivative, but it was found that the benzoyl radical gave a more desirable product, and this is now made exclusively and the name analgen applied to it. It is in colorless crystals, insoluble in water, soluble in hot alcohol, melting point 208° C.

First produced and brought forward by Vis as an antipyretic, analgesic and antirheumatic remedy, it was subsequently investigated by Maass (*Z. K. M.*, xxviii, 1895), who found that in sufficient dose it depresses the heart and the reflexes, finally causing convulsions with loss of power, and death by centric paralysis of respiration. Both it and its derivative, *oxyethylamidoquinoline,* act upon the peripheral nerves as local anesthetics. The fatal dose for the lower animals was found by Maass to be three grammes per kilo. The continuous use of small doses produces emaciation, feebleness, and lessening of the reflexes. In cases of fever it causes active depression of temperature, often with free sweating, and usually decrease in the urinary secretion, and especially of the nitrogenous elimination. After chronic poisoning in the lower animals fatty degeneration was found in the liver and kidneys. The urine of patients taking it is said to become red, owing to the presence of *oxyethylamidoquinoline urate.* In *headaches* and the other nervous disturbances of *neurasthenic* individuals it is said to act well without affecting digestion. It is said also to relieve the pain of organic diseases, and to be distinctly antimalarial. (*B. A. M.*, xxxvi.) *Dose,* eight to fifteen grains (0.5–1.0 Gm.), up to forty-five grains (0.3 Gm.) a day if required; best administered in capsule or in acidulated water.

Anchietea. *Anchietea salutaris* St. Hil. *Cipo Suma. Cipo Carneiro. Pirageia.* (Fam. *Violaceæ.*)—The bark of the root of this Brazilian plant contains *anchietine,* an alkaloid isolated by Peckoldt. (*Ber. d. Chem. Ges.*, 1897, p. 98.) It is used in Brazil in treating *scrofula, erysipelas,* and *eczema.* Given in *doses* of two drachms (7.7 Gm.), it acts as an aperient, while three drachm (11.6 Gm.) doses produce vomiting.

Anchusa. *Anchusa officinalis,* L. *Bugloss. Oxtongue.* (Fam. *Boraginaceæ.*)—The root, leaves, and flowers of this European biennial plant were at one time recognized by the U. S. Pharmacopœia, but probably are devoid of medicinal properties. According to Greimer (*A. Pharm.*, 1900, ccxxxviii, 505) it contains the alkaloids consolidine and cynoglossine (see *Cynoglossum*). It is to be distinguished from Alkanet root, which is also known as Spanish Bugloss.

In France the *Anchusa italica,* which is there known as *buglosse,* is substituted for *A. officinalis* as a diaphoretic and diuretic.

Andrographis. *Br. Add.* 1900. *Andrographis paniculata* Nees. (Fam. *Acanthaceæ.*)—Under the name of *Kiryat* this plant is stated to be used to some extent in India as a bitter tonic, having similar properties to chiretta. It appears scarcely to enter commerce at all, although exposed in the shops of the herbalists. (See *B. P. C.*, p. 122.) The Br. Add., 1900, recognized the *infusion* (*Infusum Andrographidis,* one ounce to a pint), *dose,* one-half to one fluidounce (15–30 cc.); the *concentrated liquor* (*Liquor Andrographidis Concentratus*), *dose,* one-half to one fluidrachm (1.8–3.75 cc.); and the *tincture* (*Tinctura Andrographidis*), *dose,* one-half to one fluidrachm (1.8–3.75 cc.).

Andromeda.—*Oxydendrum arboreum* (L.) DC., (*Andromeda arboreum* L.), *Sour Wood,* or *Sorreltree,* grows in the valleys of the Alleghanies, from Pennsylvania to Florida and west from Indiana to Louisiana. The decoction of the leaves was at one time used as a pleasantly acidulous drink in fevers. The powder of the leaves and buds of *Leucothoë racemosa* (L.) A. Gray (*Andromeda racemosa* L.) is said to be a powerful errhine.

In 1882 Eykman of Japan isolated from the *Andromeda* (*Pieris*) *japonica* Thunb. a poisonous principle which he named *asebo-toxin.* This principle was later found in a number of other ericaceous plants—including several species of Andromeda, as well as the *Azalea indica* L. and *Rhododendron ponticum* L.—by Plugge (*A. Pharm.*, 1883, 1 and 1885, 914) who named it *andromedotoxin.* The same principle has also been found in the *Kalmia latifolia* and *angustifolia* by Lasché (*Ph. Rund.*, Sept., 1889) and in *Monotropa uniflora* L. The chemistry and physiology of this principle has been studied by De Zaayer (*A. G. P.*, 1887, xl, 481) and by Hardikar (*J. P. Ex. T.*, 1922, xx, p. 17).

Andromedotoxin is soluble in cold water and in alcohol, less soluble in hot water, chloroform, ether or amyl alcohol, insoluble in petroleum benzine. De Zaayer gives the melting point as 228° to 229° C., but according to Hardikar it is 258°. It is a neutral, non-nitrogenous principal, precipitated neither by the alkaloidal reagents nor by metallic salts. It does not reduce Fehling Solution and is not decomposed by hot acetic acid. The symptoms of poisoning by andromedotoxin, or the various leaves containing it, are: salivation, vomiting, staggering gait, followed by convulsions, labored respirations, then a progressive paralysis of the extremities until death. The heart is at first slowed, later becomes more rapid but before death becomes slow and weak. Hardikar, from his physiological studies, concludes that the principal has a very complex action: it first stimulates, later paralyzes the peripheral ends of the vagi, which explains the respiratory and cardiac symptoms; it has a narcotic action upon the higher brain centers which is the cause of the staggering gait; it paralyzes the motor end plates in voluntary muscle which is the cause of loss of power in the extremities; in fatal doses it has a depressant action upon the cardiac muscle which explains the late slowing of the pulse; the cause of the salivation and emesis was not determined. The *poisonous honey* of Xenophon, derived from the flowers of *Rhododendron ponticum*, probably owed its toxic properties to andromedotoxin. (See also *Ph. Z. R.*, 1883, xxii,) The oil of *Andromeda Leschenaultii*, of India, was found by J. Broughton to be methyl salicylate. (*P. J.*, Oct., 1871.)

Anemonin. *Pulsatilla Camphor.* $C_{10}H_8O_4$. —From *Anemone Pulsatilla* L. Yellowish-white crystals soluble in hot alcohol and insoluble in water. It is used as an antispasmodic, sedative and anodyne in *asthma* and pulmonary affections. *Dose,* one-fourth to three-fourth grain (0.015–0.05 Gm.), although as high as three grains (0.2 Gm.) has been administered.

Anemopsis. *Yerba Mansa, Apache Beads. Anemopsis californica* Hook. et Arn. (*Houttuynia californica* B. et H.)—This is an erect, aquatic herb belonging to the *Saururaceæ,* which is found growing in the southwestern United States. The root is employed by the natives in *chronic malaria,* and also in *diarrhea* and *dysentery,* and has been used with asserted good results in *gonorrhea* and *rheumatism.* For elaborate histological study, see *D. C.*, May, 1897. *Dose* of the fluidextract, from fifteen to sixty minims (0.9–3.75 cc.). A decoction of this root was used by the Indians as a local application in cuts and ulcers as well as internally in *diarrhea* and *dysentery.* It has also been recommended as a local application in nasal and pharyngeal *catarrhs.* The investigations of Lloyd (*A. J. P.*, 1879) showed a characteristic volatile oil and a tannin together with gum and a fixed oil.

Angræcum. *Angræcum fragans* Thouars.—This is an orchidaceous plant, indigenous to the Isle of Réunion and to Mauritius, where the leaves have been long used, under the name of *faham,* for the same purposes as tea leaves. For description, see *P. J.*, 1881, 913. They have a somewhat pungent aromatic taste, and a strong and highly agreeable odor, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system somewhat similar to that of tea. (*A. J. P.*, 1866, 441.)

Anhalonium. *Lophophora. Mescal Buttons.*—The dried tops of *Lophophora Williamsii* Coulter (Fam. *Cactaceæ*) and commonly known as *Peyote* or *Mescal Buttons* is a narcotic drug obtained from a small, fleshy, spineless cactus indigenous to northern Mexico and found growing now in Zacatecas, Chihuahua and on both sides of the Rio Grande near Laredo, Texas. It was called "sacred mushroom" by the Aztecs, who, like some of the American Indians of today, used it in their religious rites and attributed to it divine properties. It is probably used also as a habit narcotic although the extent of the habit is doubtful (see Saffow, *J. A. M. A.*, 1921, lxvii, 1278).

The plant is a perennial herb whose main axis is subterranean. From this arise a number of aerial shoots which appear like peltate fungi, the disk or button-like portion being up to 50 mm. in diameter and bearing tufts of yellowish-white hairs among which spring pinkish flowers. This constitutes the "mescal button."

The species was first placed in the genus, *Echinocactus,* by Lemaire in 1845 who described it under the name of *Echinocactus Williamsii.* It was later transferred to the genus, *Anhalonium,* and subsequently made the type of a new genus, *Lophophora,* by Coulter (see "Preliminary Revision of the North American Species of Cactus, Anhalonium and Lophophora," *Contrib. U. S. Natl. Herb.*, 1894, iii, 91–132). The *L. Lewinii* seems to be a variety rather than a distinct species. The mescal button is 6 mm. in thickness, with a convex under surface, a texture which is brittle and hard when dry, but becomes soft when moistened, a very bitter disagreeable taste, and an odor when moist which is peculiar and disagreeable, and is especially marked in the powdered drug. According to C. H. Thompson, the buttons of *L. Lewinii* and *L. Williamsii* are readily distinguished by the fact that the surface of *L. Lewinii* is traversed by thirteen shallow narrow furrows giving the appearance of there being as many irregular or much broken ribs or obtuse ridges, while in *L. Williamsii* the furrows and ridges are eight in number and regular.

In 1888, L. Lewin separated from *L. Lewinii* an alkaloid, *anhalonine,* which has the formula $C_{12}H_{15}O_3N$, and crystallizes in small white prisms, soluble in ether, alcohol, and chloroform. Subsequently, Heffter (*B. Chem. Ges.*, 1896) found in it, besides *anhalonine,* three alkaloids: *mescaline,* $C_{11}H_{17}O_3N$, in white needles melting at 151° C.; *anhalonidine,* $C_{12}H_{17}O_3N$, fusing at 160° C., and *lophophorine,* $C_{13}H_{17}O_3N$. (See also ***A. E. P. P.***, 1898, xl.) Kauder (*A. Pharm.*, 1899, vol. ccxxxvii) has found that in commercial mescal buttons, besides the alkaloids already mentioned, are two other bases, *pellotine,* $C_{13}H_{19}O_3N$, and *anhalamine,* $C_{11}H_{15}O_3N$. E. White (*J. P.*, xxv) obtained *mescaline,* 1.16 per cent.; *anhalonidine,* 1.16 per cent.; *anhalonine,* 0.46 per cent.; *lophophorine,* 0.14 per cent. *Anhaline,* $C_{10}H_{15}ON$, is identical with hordenine found in barley. For further information concerning these alkaloids see Späth (*M. Chem.*, 1919, xl, and 1922, xliii).

From time immemorial the Kiowa Indians of the Rio Grande have used the mescal buttons for the purpose of producing intoxication during their religious ceremonies. Attention was first called to the peculiar cerebral action of the drug by D. W. Prentiss and Francis P. Morgan (*T. G.*, 1895), who found that from two hundred and fifteen to two hundred and thirty grains (14–15 Gm.) (four to five buttons) will produce a peculiar cerebral excitement attended with an extraordinary visual disturbance, characterized by an incessant flow of visions of infinite beauty, grandeur, and variety, of both color and form, often followed after a time by the seeing of monsters, grotesque faces, and gruesome shapes. During the intoxication there are dilatation of the pupil, muscular relaxation, and some slowing of the pulse. Loss of sense of time, partial anesthesia, weakened heart's action, great muscular relaxation, wakefulness, and in some cases nausea and vomiting also have been noted, but no distinct alteration of the respiration. These results have been confirmed by several observers.

A. Mogilewa (*A. E. P. P.*, xlix, 137) found that mescaline, anhalonidine, anhalonine, lophophorine, and pellotine acted similarly in lessening the frequency and force of the isolated frog heart, varying simply in quantitative power. Dixon (*J. P.*, xxv) in an elaborate research, came to the conclusion that the actions of the *Anhalonium* (*Lophophora*) alkaloids are qualitatively indistinguishable although there is some difference in their degree of toxicity. They are not locally anesthetic, the main effects caused in the lower animals being: salivation, slowing of the pulse accompanied with a rise of blood pressure, and increased reflexes due to stimulation of the spinal cord but associated with loss of muscular power due to a paralyzing action upon the motor nerves; in fatal doses it kills by depression of respiration and in human poisoning the most serious result is the rapid, shallow breathing. In man moderate doses produce constipation but toxic doses cause diarrhea with bloody stools. In experiments upon two human subjects, there was wide dilatation of the pupils, with uncertainty of gait like that of alcoholic intoxication, tremors, and heightened reflexes, although sensation was distinctly blunted. The psychical symptoms caused by the largest doses resemble somewhat those from cannabis indica. The *dose* of the alkaloid used by Dixon was three and eight-tenths grains (0.25 Gm.).

Pilcz (*W. K. W.*, ix, 1896) has used pellotine as a calmative in fifty-eight cases of *insanity* in *doses* of from one-third to one grain (0.021–0.065 Gm.) Sleep was produced in about half the cases.

The value of mescal buttons as a remedial agent is doubtful; it has been employed to a slight extent in various forms of *neurasthenia* and *hysteria*, and is asserted by S. F. Landry (*T. G.*, 1888) to be especially valuable in cases of *asthma*. It has also been alleged to be useful in *neuralgic* and *rheumatic affections*. Prentiss and Morgan give the *dose* of the fluidextract, from ten to fifteen minims (0.6–0.9 cc.)

Aniline. *Amidobenzene. Phenylamine.* $C_6H_5NH_2$.—This is an organic base obtained from coal tar or more immediately from nitrobenzene. It was first discovered by Unverdorben, in 1826, among the products of the dry distillation of indigo, and was named by him *Krystallin.* Fritzsche, who obtained it afterwards from indigo by another process, seems to have been the first to give it the name of aniline, from the Portuguese word *anil* (indigo). In 1837, Runge obtained three volatile principles from coal tar, which he named *kyanol, leucol,* and *pyrrhol.* Of these, kyanol was afterwards found by Hoffmann to be identical with aniline, and leucol has been ascertained to be the same as *quinoline* (*chinoline*). Zinn prepared it in 1840 by the reduction of nitrobenzene with hydrogen and called it *benzidam.* The identity of krystallin, aniline, kyanol and benzidam and the true composition of the substance was proved by Hoffmann in 1843. Aniline did not possess any commercial importance until the discovery in 1856, by Perkins, of the first of the so-called aniline colors, Perkins' purple or mauve, when the demand for aniline became so great that it became necessary to find a method for its preparation from one of the other coal tar fractions. (See *Coal Tar Colors.*) Nitrobenzene is now the source whence most of the aniline of commerce is derived. Nitrobenzene, hydrochloric acid, and iron turnings, in equal weights, are introduced into a cast iron vessel, care being taken that the heat does not rise too high, when the following reactions take place:

$$C_6H_5NO_2 + H_6 = C_6H_5NH_2 + 2H_2O$$
$$C_6H_5NH_2 + HCl = C_6H_5NH_2HCl$$

The semi-solid mass which soon forms consists principally of ferrous chloride and aniline hydrochloride. This is distilled, after the addition of milk of lime, in a large cast iron cylinder, and the distillate redistilled, the portion coming over between 175° C. and 190° C. being collected, and considered sufficiently pure for manufacturing purposes.

Properties.—Pure aniline is a thin, colorless, highly refractive fluid, of an oily appearance; but as found in commerce it is generally more or less colored, and sometimes of a deep reddish-brown. It has a peculiar, not disagreeable odor, and a pungent, aromatic, burning taste; its sp. gr. is 1.024. It solidifies at −6° C., if pure, but if impure the freezing point may be below −20° C. It boils at 183°–184° C., and its vapors are condensed unchanged. It is slightly soluble in water, but dissolves in all proportions in ether, alcohol, methyl alcohol, acetone, carbon disulphide, and the oils, fixed and volatile. As a base it is weaker than ammonia in the cold but stronger when hot. Its aqueous solution does not react with litmus or turmeric. With the acids it forms soluble and readily crystallizable salts. It is inflammable, and absorbs oxygen from the air, becoming at first yellowish, afterwards reddish, and ultimately brown. A characteristic property is that it produces instantly a deep blue or purple color when brought into contact with chlorinated lime or other hypochlorite (whence the name kyanol, of Runge). (*P. J.*, Sept., 1862, 128.) It is a derived ammonia, having the group C_6H_5 in place of a hydrogen atom of the NH_3 molecule. It is hence often called *phenylamine.* The chief value of aniline is in the manufacture of numerous derivatives, some of which are used in medicine while others form one group of the numerous so-called coal tar colors of commerce. Beautiful reds, purples, yellows, blues, and various other tints are obtained from it. Certain of the aniline or coal tar dyes possess properties which have led to their employment in medicine. (See under their various names.)

Under the name of *aniline oil* a liquid is to be found in commerce which consists of a mixture of aniline, toluidine, exylidine, cumidine, and varying quantities of by-products found in the "tailings"; it is used as a solvent for rubber, copal, etc.

Medicinal Properties.—The symptoms which are produced by the inhalation or ingestion of aniline are great prostration, heaviness in the head, giddiness, vomiting, violent neuralgic pains, and, if the dose has been large enough, cyanosis, coma with dilatation of the pupils, excessive perspiration, loss of reflexes and of voluntary movement, hurried weak pulse, rapid or irregular respiration, hemoglobinuria, a peculiar discoloration of the skin, and, if the patient survives sufficiently long, jaundice with great increase in the biliary pigment of the urine. At the autopsy reported by Müller (*A. J. P.*, 1887), in a woman killed by the swallowing of about a fluidounce (30 cc.) of aniline, the blood was chocolate brown, and gave the spectrum of methemoglobin. Dehio (*A. J. P.*, 1888) reported a case in which after one hundred and fifty grains (9.8 Gm.) of aniline, the red blood corpuscles fell to 1,400,000 on the eleventh day. Aniline is feebly antiseptic but many of its derivatives are very powerful germicides and have achieved practical importance as disinfectants.

The violent local effects which have been noticed as produced by some aniline dyes have probably been due to the presence of arsenic, which is used in their production and may remain as a contamination.

Aniline Blue. *Triphenyl-rosaniline, Toluidine Blue. Pure Blue. Water Blue.*—This dye-stuff is said to possess anti-malarial properties similar to those of methylene blue. The *dose* is five grains (0.3 Gm.) in capsules three times a day.

Aniline Sulphate, $(C_6H_5NH_2)_2H_2SO_4$, occurs in white crystals, soluble in water and alcohol. It has been used as a nervine in *chorea* and *epilepsy. Dose,* three-quarters to one and one-half grains (0.05–0.1 Gm.) three times daily. Maximum *dose,* three grains (0.2 Gm.) with the daily maximum dose of six grains (0.4 Gm.)

Anisic Acid. *Paramethoxybenzoic Acid. Draconic Acid.* $C_6H_4.OCH_3.COOH$.—It is prepared from anisic aldehyde or by oxidization from *p-kresolmethyl ether.* It forms colorless crystals which are almost insoluble in cold water and slightly soluble in alcohol and ether. As an antiseptic it is alleged to have marked power and it has also been used as an antirheumatic and antipyretic. *Dose,* five to fifteen grains (0.32–1.0 Gm.).

Anisodus. *Anisodus luridus* Link and Otto. (*Scopolia lurida* Dun.)—This is a Himalayan solanaceous plant in which Siebert has found *atropine* and *hyoscyamine.* (*A. Pharm.*, Feb., 1890; *P. J.*, March, 1890.)

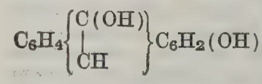
Anisole.—This name has been applied to the *methyl ether of phenol* because of the fact that it was at one time manufactured from anisic acid. It has been found by Professor Fraenkel to be an active agent against *lice* and other body vermin.

Annatto. *Orleana. Annotta. Arnotta. Terre de la Nouvelle-Orléans. Roucou,* Fr. *Orellana, Orlean,* G.—This coloring substance, which is called by the natives *urucu* or *bija,* is the reddish pulp surrounding the seeds in the fruit of *Bixa orellana* L. (Fam. *Bixaceæ*), a middle-sized tree native to northern South America, but widely cultivated in tropical Asia and Africa. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to settle. The mass which remains is dried and formed into flat cakes or cylindrical rolls. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The coloring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annatto, the Spanish or Brazilian, and the French, the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called *flag annatto,* has a disagreeable odor, probably from having been prepared by the fermenting process in which urine is sometimes used; but is superior, as a dye stuff, to the Spanish, which is without any disagreeable odor. Annatto is of a brownish-red color, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odor and a disagreeable saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow color, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The South American Indians are said to produce directly from the annatto seeds, without fermentation, a color similar to and almost as brilliant as carmine. (*P. J.*, April, 1903.) For a proximate analysis of the leaves see *Ap. Ztg.*, 1899, p. 35. It contains a peculiar coloring principle, to which Preisser, its discoverer, gave the name of *bixin.* This has the formula $C_{28}H_{34}O_5$, and when pure is a dark, red, somewhat crystalline substance. According to Van Hasselt, bixin has the composition $C_{29}H_{34}O_5$, but Heiduschka and Riffart believe that the correct formula is $C_{28}H_{34}O_5$. (*A. Pharm.*, 1911, No. 1, 39.) It is accompanied by a yellow coloring matter, *orellin.* A coloring matter found in the root of *Escobedia scabrifolia* Ruiz et Pavon, a plant growing in tropical America, is used by the Mexicans in coloring fats and butter yellow. (*S. W. P.*, 1912, No. 18, 260.)

The chief uses to which annatto is applied are for dyeing silk and cotton orange-yellow, and for coloring cheese and butter. The color, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is employed to color ointments and plasters, and has occasionally been substituted for saffron. It is frequently adulterated with red ochre, powdered bricks, colcothar, farinaceous substances, chalk, calcium sulphate, turmeric, etc. The mineral substances, if present, will be left behind when the annatto is burned. *Tincture of annatto* is made by extracting 100 parts of annatto with 100 parts of water containing 1½ per cent. of potassium carbonate, and evaporating to 60 parts, mixing with 12 parts of alcohol and filtering.

Anona.—The seeds of *A. squamosa* L., *Sugar Apple* or *Sweet Sop* of the West and East Indies, are said to be poisonous and to be used to kill lice, while the bark is a drastic cathartic. The seeds of *A. muricata,* L., *A. palustris,* L., and *A. spinescens,* Mart., are employed to poison fish and to exterminate destructive insects. (*Ph. Rev.*, Oct., 1896.)

Anthrarobin. *Anthro-arobin. Leucoalizarin.*



$$C_6H_4\left\{\begin{matrix}C(OH)\\|\\CH\end{matrix}\right\}C_6H_2(OH)_2$$

—This substance, which is produced from commercial alizarin by reduction, was first described by Liebermann (*Ber. d. Chem. Ges.*, 1888), and proposed as a substitute for chrysarobin. It is a yellowish-white granular powder, almost insoluble in water and acidulated solutions, sparingly soluble in chloroform and ether, and readily soluble in alcohol and weak alkaline solutions. It mixes readily with fats to form ointments. It is a powerful reducing agent, and has been used by G. Behrend, (*Th. M.*, 1888), and other clinicians, with asserted advantage in those diseases for which chrysarobin is employed. In alkaline solution anthrarobin readily absorbs oxygen and is reconverted into the blue alizarin. It is incompatible with hydrogen dioxide, potassium permanganate and other oxidizing agents. As a topical application, the ointment or the alcoholic solution (each 10 per cent.) may be used.

Anthrasol. *Colorless Coal Tar.*—Anthrasol is coal tar freed from bases such as pyridin and chinoline by acid treatment and from pitch by distillation. The distillate is purified to remove coloring principles and juniper tar is added to prevent separation of solid constituents. Oil of peppermint is added to correct the odor. It is a thin, mobile, light-yellow oil which stains neither skin nor fabric. Anthrasol is in skin diseases in strengths varying from 5 to 30 per cent.

Anthriscus. *Anthriscus cerefolium* (L.) Hoffm. (*Chærophyllum sativum* Lam. *Scandix cerefolium*, L.), *Chervil.*—An annual European plant of the Fam. *Umbelliferæ*, cultivated in gardens as a pot-herb, and naturalized in Eastern and Southern Pennsylvania. It has a strong agreeable odor, and a pungent, slightly bitterish taste. It contains a volatile oil of very feeble medicinal power, but it has been used as an emmenagogue and diuretic.

Antiaris.—Among the Asiatic arrow poisons one of the most important, which has long been used by the natives of Java and other East Indian Islands under the name of *Upas antiar*, is a gum-resinous exudation obtained from *Antiaris toxicaria* Lesch., a large tree belonging to the *Urticaceæ*, growing in Java, Celebes, and the neighboring islands. This plant is said to exhale a volatile poison which very unpleasantly affects some of those who approach it, causing eruptions upon the skin attended with much swelling; hence the fable of the *deadly upas tree.* The juice is mixed with various substances to give it due consistency. Whether taken internally or introduced into the system through a wound, upas acts with extreme violence, producing vomiting, great prostration, a feeble, irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death.

Pelletier and Caventou obtained from it a glucoside, *antiarin*, crystallizable, soluble in water and alcohol, but scarcely so in ether, and of the formula $C_{14}H_{20}O_5$. According to Kiliani (*B. Chem. G.*, 1910, xliii, p. 3574), there are two glucosides, namely, *alpha-* and *beta-antiarin.* For the first of these he suggests the formula $C_{27}H_{42}O_{10} + 4H_2O$, while the formula for the second is uncertain, but may be $C_{22}H_{30}O_8$. Antiarin is a muscle poison, producing first strong fibrillary contractions of the voluntary muscles, followed by a rapid decrease in irritability and finally paralysis, the sarcolemma of the muscles and not the motor nerve endings being the part attacked. It also belongs to the digitalis group of cardiac stimulants, raising the blood pressure at first, and finally arresting the heart in systole. According to Stockman, antiarin diminishes the irritability of the peripheral vagi and stimulates the vasomotor centers. H. W. Bettink claims (*Ned. Tijdschr. v. Pharm.*) that besides antiarin there are present in *Upas antiar* two other active principles, *œpaïn* and *toxicarine.* Headborn (*A. E. P. P.*, 1901, xlv,) states that *antiarigenin*, a derivative of antiarin, is more powerful than antihydropin itself. See also *Arrow Poisons.*

Antiluetin. — *Potassium-ammonium-antimonic bitartrate*, $SbO(C_4H_4O_6)_2K(NH_4)_2.H_2O$, has been used by Tsuzuki (*D. M. W.*, 1913, p. 825) in the treatment of *syphilis.* The beginning dose he used was two-fifths of a grain (0.025 Gm.) increased rapidly to three-fourths of a grain (0.05 Gm.).

Antimony Arsenate.—This is a heavy, snow-white powder, containing 80 per cent. antimonic oxide and 20 per cent, arsenic acid (Merck). *Antimony arsenite*, on the other hand, is said to contain equal parts of the two ingredients, arsenous acid and antimonic oxide. It is stated that antimony arsenate is used in Russia as an alterative in *doses* of one-fiftieth of a grain (0.0013 Gm.) four times a day. (*A. J. P.*, xliv, 301.)

Antimony Colloidal. *Colloidal Antimony* Crookes, is a product containing metallic antimony made by chemical methods, which is remarkably stable. It is not broken down by electrolytes and has been kept unchanged for four years.

Colloidal Antimony Sulphide is made by saturating a 0.5 per cent. solution of tartar emetic with hydrogen sulphide and removing the acid potassium tartrate by dialysis. The reddish turbid liquid which results is adjusted by assay so as to contain 0.2 per cent. antimony sulphide; glucose is then added to make the liquid isotonic, acacia to render physically stable and phenol to preserve. It has been used by Rogers (*L. L.*, 1919, cxcvi, 505) intravenously up to 20 cc. of the 1 to 500 solution in *kala-azar.*

Colloidal Antimony has been used by several investigators in the treatment of *leprosy* with asserted beneficial results. Cawston (*B. M. J.*, December 4, 1920 and March 19, 1921) uses intramuscular injections of a preparation known as *Oscol Stibium.* He gives four injections, beginning with 2.5 cc. (40 minims) and increasing to 5 cc. (80 minims), every day for four days. This treatment, he asserts, leads to a rapid disappearance of at least the external evidence of the disease. Wildish (*B. M. J.*, January 14, 1922) has obtained similar favorable results, not only from Oscol Stibium but also from *Crooke's colloidal antimony* and from ordinary tartar emetic.

Antimony Crocus. *Crocus of Antimony. Saffron of Antimony.*—This compound is formed during the deflagration of a mixture of equal weights of antimony trisulphide and potassium nitrate, to which one-twelfth of hydrochloric acid has been added. Fused crocus of antimony is in masses of a liver-brown color; the unfused is a saffron-brown insoluble powder, containing about four-fifths of trioxide, and one-fifth of trisulphide. It was formerly used in making tartar emetic.

Antimony, diaphoretic. *Antimonium Diaphoreticum. Potassii Biantimonias. Antimoine diaphorétique lavé*, Fr.—This compound may be formed by deflagrating in a crucible, and keeping red hot for fifteen minutes, a mixture of pure antimony with three times its weight of potassium nitrate. The product, washed with water and dried, is *washed diaphoretic antimony.* For improved process, see 14th edition of *U. S. D.*, p. 1640. *Dose*, from one-half to two drachms (1.9–7.7 Gm.). This form of antimony is weak, variable, and rarely used.

Antimony Glass. *Vitrum Antimonii.*—This is prepared from antimony trisulphide by a partial roasting and subsequent fusion. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is very seldom used. For further information concerning this substance, see *U. S. D.*, 19th edition, p. 1391.

Antimony Aniline Tartrate. $SbO.C_6H_5NH_2.$-$C_4H_4O_6$.—According to Loweran, this occurs in colorless, yellow crystals, soluble in water, containing 22 per cent. of antimony. Although antimony and potassium tartrate has been used both experimentally and clinically in the treatment of trypanosome infections, its high toxicity has discouraged the hope of its proving a useful therapeutic agent. The antimony and aniline tartrate, which was first prepared by C. S. Evans, was found by Loweran (*C. R. A. S.*, 1909, p. 546) to be much less toxic to the higher animals and to be an efficient trypanocide in guinea-pigs. Thiroux has used it clinically in the treatment of *sleeping sickness*, and, although it is as yet too soon to say definitely concerning its value, his results are at least encouraging. He injected in intravenously in *doses* of one-fourth of a grain (0.015 Gm.).

Antimony Iodide. SbI$_3$. *Antimonii Iodidum. Antimony Triiodide* or *Teriodide.*—According to W. Copney, of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one part to three. The elements combine with sudden heat and liquefaction, and, upon the withdrawal of the heat, the iodide formed solidifies, and is removed by breaking the flask. Antimony iodide, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is decomposed. An amorphous variety is prepared by action upon antimony oxide with potassium iodide in the presence of anhydrous acetic acid. It formed a yellow powder which is more stable than the crystalline variety. (*Chem. News*, 1918, cxvii, 306.) It has been tried as an alterative in *doses* varying from one-fourth to one-half grain (0.016–0.03 Gm.), given in pill.

Antimony Sulphide. *Antimonium Nigrum*, Br. 1864. *Black Antimony. Japanese Antimony. Antimony needle. Sulphuret of Antimony. Stibium Sulfuratum Crudum, Antimonium Crudum. Sulfuretum Stibicum. Sulfure d'Antimoine de commerce*, Fr. Cod. *Antimoine sulfuré, Antimoine cru*, Fr. *Stibium sulfuratum nigrum*, P. G. *Schwefelantimon, Schwefelspiessglanz*, G. *Antimoino crudo*, Sp. *Antimonii Sulphidum*, U. S. 1890. *Antimony Trisulphide.* Sb$_2$S$_3$; 334.09.—"Native antimony sulphide, purified by fusion and as nearly free from arsenic as possible." *U. S.*, 1890.

The antimony sulphide which is found in commerce is obtained from the native sulphide, called *antimony ore*, by different processes of purification. Much of the "Black Antimony" of commerce at one time contained no antimony whatever, but was simply powdered coal and marble; it was easily distinguished by its low specific gravity; a dry, tared one-ounce bottle will hold, after shaking down, two and a quarter ounces of powdered black antimony, but only one and a quarter ounces of powdered coal. (*Proc. A. Ph. A.*, 1885, 479.)

Antimony sulphide should never be triturated with a strong oxidizing agent as an explosion is liable to occur. When exposed to the air it is partially converted into the oxide.

Antimony sulphide is mostly prepared in France and Germany. It is called, in commerce, antimony, or *crude antimony*, and occurs in fused conical masses, denominated "loaves." "Steel-gray masses of a metallic luster and a striated crystalline fracture, forming a black or grayish-black, lusterless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide." *U. S.*, 1890.

This preparation is very uncertain in its operation, and ought not to be used in medicine. It has, however, been employed as a diaphoretic and alterative in *scrofula, glandular obstructions, cutaneous diseases*, and *chronic rheumatism.* It is used in the United States solely in veterinary practice. The *dose* for a horse or cow is from ten to thirty grains (0.65–2.0 Gm.), to be given in powder or bolus. For further information concerning antimony sulphide, see *U. S. D.*, 19th edition, p. 1391–1392. See also under *Antimony Colloidal.*

Antimony Sulphide, Purified. *Antimonium Nigrum Purificatum*, Br. 1898. *Antimonous Sulphide. Antimonii Sulphidum Purificatum*, U. S. 1890. *Purified Black Antimony. Sulfure d'Antimoine pur*, Fr. Cod. *Gereinigtes Schwefelantimon*, G. *Trisolfuro di antimonio depurato*, It.—"Native antimonious sulphide, Sb$_2$S$_3$, from which siliceous matter has been removed by fusion, reduced to fine powder, and, if any salt of arsenium be present, purified by digesting with half its weight of solution of ammonia for several days, washing and drying." *Br.* The purpose of washing the antimony sulphide with ammonia is to remove any foreign metals, especially copper and arsenic, which may be present in the native ore.

It is "a heavy, grayish-black, lusterless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat it fuses to a dark brown liquid." *U. S.*, 1890. This preparation is not used in medical practice, but is used in the manufacture of sulphurated antimony (see *Antimonium Sulphuratum*, Part I).

Antimony Trichloride. *Butter of Antimony.* SbCl$_3$.—Prepared by subliming antimony sulphide with mercuric chloride, by the action of dry chlorine on the sulphide or metal, or by dissolving the sulphide in hydrochloric acid and concentrating the solution of the chloride; in the latter method the product is usually colored by contamination with iron, but by distillation the pure chloride will finally pass over, the distillate solidifying in a mass of fine white crystals. Antimony trichloride is a deliquescent, soft mass, known as butter of antimony, which melts at 72° C. and boils at 223° C. It is very hygroscopic and corrosive. The addition of water produces the oxychloride known, when dry, as *powder of Algaroth.* A solution was recognized in the Br. Ph., 1885, and is used in medicine as a caustic. McDonald and Hill have improved the formula for *solution of chloride of antimony* by dissolving 132 grains of antimonious chloride in 3 fluidrachms of hydrochloric acid and sufficient distilled water to make 1 fluidounce. If it is desirable to have a tinted solution, add 15 grains of ferric chloride to each fluidounce. (*P. J.*, 1908, 86.) It is extensively used to give a bronze surface to iron and steel ware. For account of fatal poisoning by butter of antimony see Bell, *B. M. J.*, June 10, 1922, 917.

Antimonyl Sodium Tartrate. *Sodium Antimonyl Tartrate.*—This salt is analogous to the official tartar emetic except that it is a compound of sodium instead of potassium.

Napier (*Indian Med. Gaz.*, 1922, lxx, 10) used an especially pure preparation of sodium antimonyl tartrate for intramuscular injections in the treatment of *kala-azar* with asserted advantage over the tartar emetic.

Antinosin. *Sodium tetra-iodophenolphthalein.* $(C_6H_2I_2ONa)_2C.O.C_6H_4O$.—A blue powder, soluble in water and employed as a succedaneum for iodoform or as a surgical antiseptic in 0.1 to 0.5 per cent. wash. (See also *Nosophen.*)

Antipyrin Sulphanilate. *Beta-Sulphopyrin. Sulfopyrine.*—This combination of antipyrin with sulphanilic acid consists of a white powder fairly soluble in warm water and having a pronounced acid taste. It is asserted to be a specific in the treating of *iodism* and is also used in *asthma* and *influenza*, etc. *Dose,* fifteen grains (1 Gm.) three or four times daily.

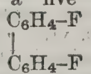
Antipyrine Tannate.—This is described as a yellow powder, insoluble in water, soluble in alcohol, and containing 37 per cent. of antipyrine. It is stated that it may be made by adding concentrated aqueous solutions of its constituents in the proportion of fifty parts of antipyrine to twenty-eight and a half parts of tannic acid. It has been specially recommended on account of its tastelessness, but is probably not an eligible preparation. Its incompatibilities are numerous, including those of both antipyrine and tannin.

Antithermin. *Phenylhydrazin-lævulinic Acid,* $C_6H_5.N_2O = C(CH_3).C_3H_5O_2$.—This substance, occurs in colorless crystals, insoluble in cold water, soluble in ether and hot alcohol, melting point 108° C. It was used as an antipyretic by Drobner (*W. M. P.*, 1892, 540), who finds it active in *doses* of from eight to ten grains (0.5–0.65 Gm.). It produces pallor, excessive sweating, and other evidences of vasomotor depression.

Antithyroidin Moebius. *Serum Antithyroideum. Thyroidectomized Serum.*—This is the blood serum of sheep from which the thyroid gland has been removed, at least six weeks before the blood is drawn, preserved with 0.5 per cent. of phenol. It is an amber-colored fluid, with the faint odor and taste of phenol. It is marketed in vials containing two and a half drachms (10 cc.). With proper precautions it is said to keep indefinitely. It is employed in the treatment of *exophthalmic goitre.* It is administered either hypodermically or by the mouth in *doses* beginning with eight to fifteen minims (0.5–1.0 cc.) three times a day, gradually increasing the dose.

Antituman. *Sodium Chondritin Sulphate.*—Oestreich (*B. K. W.*, 1910) having observed that in carcinoma the arterial walls and cartilaginous tissues were not affected, believed that this immunity of these tissues was due to some substance found in them. On this theory he has employed *sodium chondritin sulphate* in the treatment of *cancers.* According to his observations, the remedy lessens suffering and improves the general health of patients who are suffering with inoperable cancers. Because of the pain which follows the injection of the remedy, it is marketed in combination with eucaine. The beginning *dose* is one and a half grains (0.1 Gm.) once or twice a day subcutaneously, which may be gradually increased.

Antitussin.—*Antitussin* is a five per cent. ointment of *di-fluordiphenyl,*



$$\begin{array}{l} C_6H_4\text{–}F \\ | \\ C_6H_4\text{–}F \end{array}$$

which occurs as colorless crystals melting at 87° C. It is a white aromatic powder, insoluble in water, freely soluble in alcohol, ether, and chloroform, was originally recommended by J. Thimm as a local remedy in the treatment of *syphilitic ulcers* or *wounds,* applied either as a ten per cent. dusting powder or a ten per cent. ointment. (*Derm. Zeit.*, iv, No. 15.) Antitussin has been strongly recommended by Max Heim (*B. K. W.*, Dec., 1899) in the treatment of *whooping cough.* It is an ointment consisting of five parts of di-fluor-di-phenyl, ten parts of vaselin and eighty-five parts of lanolin. For a child a year old, about one-half drachm (2 Gm.) is slowly rubbed into the skin daily on the back, chest, and abdomen, about a drachm (3.9 Gm.) being used for a child five years old. (See also *Merck's Annual Reports,* 1905, 22 and 1907.)

Anusol.—A proprietary suppository, alleged to contain a bismuth compound of *iodo-resorcin-sulphonic acid,* but it is apparently a mixture of zinc oxide, resorcinol, bismuth oxyiodide, balsam of Peru, and cacao butter. (*West. Drug.*, 1898, 75; *J. A. M. A.*, 1911, lvi, 441.) It is used in the treatment of *hemorrhoids.*

Aperitol. *Valothalein.*—Under this name is marketed a palatable form of *iso-valeryl-acetyl phenolphthalein* formed by the combination of esters of isovalerianic acid and acetic acids, in equal proportions.

This substance, which has been introduced as a cathartic, appears to be without any toxic action upon the system, for Hammer and Veith (*Med. Klin.*, 1908, iv) fed fifteen grains (1 Gm.) to a dog daily for ten days without any apparent effect. The same authors report a case in which a man took by mistake twenty-four grains (1.6 Gm.) without any more serious symptom than catharsis. Those who have employed the remedy are almost unanimous in the statement that it causes catharsis without (except in very occasional cases) any griping.

Aphloia theæformis Benn. (Fam. *Bixaceæ*).—This plant is a native of Madagascar and is claimed to possess marked alterative properties and beneficial effects upon hemoglobin. It is administered as an infusion of the leaves, 30 Gm. of the plant being used to make 1 liter of infusion.

Apinol. *N. N. R.*, 1924.—This is a product obtained in the destructive distillation of the wood of *Pinus palustris* Mill. (*Pinus australis* Michx.). It is stated to consist mainly of *lævo-menthone,* $C_{10}H_{13}O$. It is a clear amber-colored oil, of neutral reaction with a pine odor and having a sp. gr. of 0.946 and a boiling point of 182° C. It is used locally as an antiseptic and anesthetic application for *wounds.* It is also employed as an expectorant in chronic catarrhal conditions of the respiratory tract in *doses* of five to ten minims (0.3–0.6 cc.).

Aplopappus. *Aplopappus* (*Haplopappus*) *Baylahuen* Remy.—This composite herb is a native of Chili, where it is said to be relied upon as a stimulant in *flatulent dyspepsia* and *chronic inflammation* with *hemorrhage* of the lower bowels. It has been analyzed by H. H. Rusby (*A. J. P.*, 1890, 488), and later by H. Kahn (*A. J. P.*, 1891, 377). The former found a volatile oil, a fatty oil which had the specific odor of the plant, a brown acid resin of sharp taste, and tannin. The latter determined the percentage of volatile oil as 6.65, and of resin as 21.15. He also considers that this resin is a mixture of four different resins. G. Baille asserts (*B. G. T.*, Feb., 1889) that the remedy is valuable not only in *dysentery,* but in *genito-urinary catarrhs,* and also as a stimulating expectorant. *Dose,* one-half to one tablespoonful (7.5–15 cc.) of a strong decoction, one part to five, may be given every two hours; or the fluidextract, from five to twenty minims (0.3–1.3 cc.).

It has also been used in tincture form as an application to slowly healing *wounds* and *ulcers.*

Apocodeine Hydrochloride. $C_{18}H_{19}NO_2HCl$.—It is a greenish-yellow powder, soluble in water. Apocodeine has been investigated physiologically by W. E. Dixon (*B. M. J.*, 1902) who found that it lowered blood pressure by dilating the blood vessels, increased the intestinal peristalsis and produced a large secretion of saliva. Foy and Combemale (*R. T.*, 1907) have both employed it hypodermically as a laxative with pleasing results. Thirty minims (1.8 cc.) of a 1 per cent. solution may be injected deeply into the muscles.

Apolysin. *Aconitylphenetidin. Monophenetidin Citrate.* $C_6H_4.OC_2H_5.NH(C_6H_7O_6)$.—A compound made by heating together citric acid and phenetidin with one molecule of water. It is a crystalline, yellowish-white powder of peculiar odor and taste. Its melting point is 72° C. It is soluble in cold water (1 in 25), alcohol, and glycerin, and in concentrated sulphuric acid without change of color. The solution in nitric acid turns a pale orange color. The aqueous solution is not clouded by silver nitrate, nor the acid solution by hydrogen sulphide. For tests of purity, see *Zeit. Oest. Apoth. Ver.*, 1910, 301. R. Seifert (*D. M. W.*, xxi, 1895) asserts that in *doses* of from eight to twenty-four grains (0.5–1.6 Gm.), three or four times a day, it is a valuable remedy as an antipyretic in various febrile diseases, and possessed of great power as an analgesic, similar in range of usefulness to acetphenetidin, but free from poisonous properties or disagreeable after effects.

Apomorphine-methylbromide. $C_{17}H_{17}NO_2\text{-}CH_3Br$. *Apomorphine Bromomethylate. Bromophin. Euporphin.*—This occurs in colorless or yellowish crystals soluble in either water or alcohol. It is used as a nauseating expectorant in *acute bronchitis* and is asserted to have the advantage over apomorphine of being more stable and less liable to produce vomiting. The *dose* is from one-twentieth to one-twelfth of a grain (0.003–0.005 Gm.).

Apothesine. $C_6H_5(CH)_2.CO_2.(C_2H_5)_2N(CH_2)_3\text{-}HCl$. *Di-ethylamino-propyl-cinnamate Hydrochloride.*—This occurs as a crystalline powder with a melting point of 137° C. Readily soluble in water or alcohol. It is precipitated from its aqueous solution by alkaloidal reagents.

Apothesine has been introduced as a local anesthetic. According to Sollmann (*J. P. Ex. T.*, 1918, xi, p. 71) its anesthetic efficiency is about one-eighth that of cocaine, and the experiments of Eggleston and Hatcher (*J. P. Ex. T.*, 1919, xiii, p. 433) show that it is slightly less toxic than cocaine.

According to the experiments of Macht, Satani and Swartz (*Journ. of Urology*, Aug., 1920) apothesin has distinct antibacterial powers, 0.5 per cent. solution killing gonococci and staphylococci after 24 hours' exposure.

Aquilegia. *Aquilegia vulgaris*, L. *Columbine.*—A perennial herbaceous plant of the Fam. *Ranunculaceæ*, indigenous to Europe, but cultivated in our gardens. At one time considered diuretic and diaphoretic, columbine is not at present used in practical medicine. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1394.

Archidendron. *Archidendron Vaillantii* F. Muell.—The bark and black beans of this leguminous plant of New South Wales are said to be an active paralyzant to the motor side of the spinal cord. (Bancroft, *Proc. Roy. Soc. N. S. W.*, 1886.)

Areca Nut. *Semen Arecæ. Betel Nut. Noix d'Arec*, Fr. *Arekanüse, Betelnüse*, G.—The *Areca Catechu*, L., is an East India palm. The fruit, which is ovoid and from 2 to 3 cm. in diameter, and of an orange-yellow color, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, the betel nut of commerce, is of a rounded-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn color, so as to present a reticulate appearance, internally brownish-red with whitish veins, very hard, of a feeble odor when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin and various saline substances. It yields its astringency to water, and in some parts of Hindustan an extract is prepared from it having the appearance and properties of catechu. A red coloring matter known as *Areca red* is extracted, probably resulting from the decomposition of a tannin. It is insoluble in cold water and ether, soluble in boiling water and alkaline liquids, out of which it is precipitated by acids. E. Jahns (*B. Chem. G.*, 1888, xxi, 3404) has found three alkaloids in areca nut: 1. *Arecoline*, $C_8H_{13}NO_2$, identical with the *arekane* of Bombalon. 2. *Arecaine*, (*arecaidine*) $C_7H_{11}NO_2 + H_2O$, which occurs in permanent, colorless crystals, soluble in water, insoluble in absolute alcohol, ether, chloroform, and benzene. 3. An alkaloid which exists in such small quantities that sufficient was not obtainable for close examination. On heating arecoline with strong hydrochloric acid to 150° C. it is decomposed into methyl chloride, CH_3Cl, and *arecaivine.* The third alkaloid of Jahns is probably *guvacine*, $C_6H_9NO_2$, of which the methyl derivative is the base arecaidine before mentioned. In addition to the alkaloids found by Jahns, Emde (*Ap. Ztg.*, 1915, xxx, p. 240) has reported *arecolidine* and Hess (*B. Chem. G.*, 1918, li, p. 1004) *guvacoline.* These alkaloids have been more closely studied by Winterstein and Weinhagen (*Zeit. P. C.*, 1918, civ, p. 48) and by Hess and Liebbrandt (*B. Chem. G.*, 1918, li, p. 1004). From their studies it is apparent that guvacoline and arecoline are the methyl esters respectively of guvacine and arecaine (arecaidine). Meyer (*Monatsh. Chem.*, 1902, xxiii, p. 22) has shown that arecaine is a *methyltetrahydro-nicotinic* acid and it has been prepared synthetically.

Immense quantities of areca nut are consumed in the East, mixed with the leaves of the Betel pepper (*Piper Betle*, L., *Chavica Betle* (L.) Miq.) and with lime, forming the masticatory so well known by the name of *Betel.* The red color which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. (See *N. R.*, 1876, 71.) Arecoline resembles pilocarpine in its effects on the system. (Pätz, *Z. E. P. T.*, 1910, vii.) According to Jahns (*B. G. T.*, 1889) arecaine is the active principle of the areca nut, and a powerful tænicide, and is an active poison with an action of the type of muscarine and pilocarpine. Locally applied, or when given internally, it contracts the pupils.

Arecoline hydrobromide, $C_8H_{13}NO_2HBr$, a commercial salt, according to the experiments of Fröhner, is more powerful as a stimulant to the salivary glands than pilocarpine, and more active as a laxative than eserine. It is commended by veterinarians in the colic of horses, given subcutaneously in the *dose* of from one to one and one-half grains (0.065–0.096 Gm.). In human medicine it has been used in the dose of from one-fifteenth to one-tenth grain (0.004–0.006 Gm.) against the *tape worm* and as a myotic. A one-half to one per cent. solution produces a myosis, which reaches its maximum in about ten minutes and begins to subside in half an hour. It is claimed by various ophthalmologists that although in *glaucoma* its action is very transient, it produces a more considerable reduction of the intra-ocular pressure than can be obtained either with pilocarpine or eserine. It may cause considerable irritation but does not injure the continuity of the epithelium.

In India the areca nut has long been used as a vermifuge, the dose being a teaspoonful of the freshly grated nut, and its value against the *tape worm* has been confirmed by various European and American practitioners. The usual *dose* is from one to two drachms (3.9–7.7 Gm.). In this country the nut has also been used for the making of a hard charcoal, employed as a basis of tooth-powder.

Argemone. *Argemone mexicana,* L. *Prickly Poppy. Argémone,* Fr. *Stachelmohn,* G.—An annual plant, belonging to the *Papaveraceæ,* growing in our Southern and Western States, Mexico, the West Indies, Brazil and in many parts of Africa and Southern Asia. For an illustrated paper on the structure of the seed of this plant by Schlotterbeck and Eckler, see *Proc. A. Ph. A.,* 1906, 467. The whole plant abounds in a milky, acrid juice, which becomes yellow on exposure, and has been used as a local application in obstinate *cutaneous diseases,* especially that affection known in Upper India as *dhad,* and also in cases of *warts* and even *chancres.* The alleged presence of morphine in *Argemone mexicana* has been disproven by J. O. Schlotterbeck (*Proc. A. Ph. A.,* 1901, p. 247), who finds that the plant contains berberine, besides an alkaloid, *protopine* ($C_{20}H_{19}O_5N$). This alkaloid, also called *macleyine* and *fumarine* when obtained from other plants, is the *Argemonine* of Peckoldt. The seeds of the plant have been used in *colic,* 8 grains (0.5 Gm.), given in emulsion, and repeated if necessary every half hour until three doses have been taken. (*P. J.,* xiii, 642.) For further information concerning this drug, see *U. S. D.,* 19th ed., p. 1395.

Argulan.—This preparation is stated by Kolle and Rothermundt (*Med. Klin.,* 1913, p. 835) to be an antipyrine sulphamino-mercury, and to represent 46.8 per cent. of mercury. It occurs as white crystalline substance, insoluble in water. It is used in the form of an oily suspension for hypodermic injection in the treatment of *syphilis.* According to Mentberger the injections are quite painful and the antiluetic effect not superior to other preparations of mercury (*Ap. Ztg.,* 1915, p. 580). It is used in *doses* of five one-hundredths to two-tenths gramme (1–3 gr.).

Arhovin. $C_{10}H_{13}C_6H_4(COOC_2H_5)(C_6H_5)_2NH$.—This is asserted to be a mixture of *diphenylamine, thymolbenzoate* and *ethylbenzoate* in molecular proportion. It occurs as a yellowish aromatic liquid with a mentholic taste, and is readily soluble in alcohol, and the fatty oils. It has been used as a urinary antiseptic in *cystitis* and *urethritis* and also as a local application in *vaginitis* and *endometritis.* According to Burchard and Schlockow (*Med. Woch.,* 1903), the ingestion of twelve 4-minim capsules over a period of three days imparted to the urine a marked antiseptic power. Although there have been a large number of favorable reports concerning this preparation, Deutsch (*W. K. W.,* 1906) and others have not had successful results from it. The *dose* for internal administration is from four to eight minims (0.25–0.5 cc.) repeated several times a day. For local application a 5 per cent. solution in olive oil may be employed.

Aristochin. *Aristoquin. Aristoquinine. Diquinine carbonic ester.* $CO(C_{20}H_{23}N_2O_2)_2$.—A white or pinkish amorphous powder, soluble in alcohol, ether, chloroform, glycerin, and dilute acids, but insoluble in water. It is incompatible with alkalies and acids, being decomposed with the liberation of quinine. It is said to contain 96 per cent. of quinine, and probably is an effective antiperiodic, but has been chiefly used in *whooping cough.* It has the advantage over quinine of being practically tasteless. The *dose* for infants is about one grain (0.06 Gm.); for adults eight to fifteen grains (0.5–1.0 Gm.).

Aristolochia.—There are several species of the genus *Aristolochia* which are found in the herbalists' stores of India but do not enter commerce. Of these *A. bracteata* Retz is employed as an emmenagogue. Aristolochia of the Br. Add. was the dried stem and root of *Aristolochia indica* L. As sold in commerce this drug consists chiefly of stems with attached roots and is employed for the cure of *snake bite* and to produce abortion. The possession by it of any distinct medicinal properties is very doubtful. Later investigation has shown *A. rotunda* L. to contain *aristolochine,* $C_{32}H_{22}N_2O_{13}$, which has been used in Europe as a general tonic in febrile debility. The Br. Add. recognized the *concentrated liquor* (1 in 2 of 20 per cent. alcohol) (*Liquor Aristolochiæ Concentratus,* Br. Add.), *dose,* one-half to two fluidrachms (1.8–7.5 cc.); the *tincture* (1 in 5 of 70 per cent. alcohol) (*Tinctura Aristolochiæ,* Br. Add.), *dose,* one-half to one fluidrachm (1.8–3.75 cc.). Among the other species of *Aristolochia* which have been used medicinally *A. Clematitis* L., *A. longa* L., *A. rotunda* L., are still retained in official catalogues of the continent of Europe, where they are indigenous. *A. Pistolochia* L. of Southern Europe appears to have been the aristolochia of Pliny and is still used under the name of *Pistolochia.* The rhizome of *A. Clematitis* is very long, cylindrical, about 5 mm. in diameter, as a goose-quill or thicker, variously contorted, beset with the remains of the stems and roots, of a grayish-brown color, a strong, peculiar odor, and an acrid, bitter taste; that of *A. longa* L. is spindle-shaped, from 5 cm. to 3 dm. in length, about 2 cm. in thickness, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong, disagreeable odor when fresh; that of *A. rotunda* L. is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odor and taste; that of *A. Pistolochia* L. consists of numerous slender yellowish or brownish rootlets, attached to a common head, and possessed of an agreeable aromatic odor, with a taste bitter and somewhat acrid.

Aristolochine ($C_{32}H_{22}O_{13}N_2$ or $C_{17}H_{11}O_7N$) is the *aristolochic acid* of Hesse. It was isolated from *A. clematidis* and *A. rotunda* by Pohl (*A. E. P. P.,* 1891, xxix, 282). *Aristinic acid* ($C_{18}H_{13}$-

O_7H) and its isomer *aristidinic acid* as well as *aristolic acid* ($C_{15}H_{11}O_7N$) have been isolated by Hesse (*P. J.*, 1891, li, 551) from *A. argentina.*

Many species of Aristolochia, growing in the West Indies and Southern America, have been used medicinally; *A. cymbifera* Martius, known in Brazil as *milhommen, jarra, jarrinha,* and in Mexico as *guaco,* is said to have medicinal properties similar to those of the official species, but Butte affirms that it is depressant to the sensory nerve centers and is useful in *neuralgia* and *pruritus.* In the Argentine Republic the root of *A. argentina* is used as a diuretic and diaphoretic, especially in *rheumatism.* In the East Indies *A. indica* L. is employed for similar purposes with the European and American species, and the Arabians are said by Forskhal to use the leaves of *A. sempervirens* as a counter-poison. *A. fœtida* Kunth, of Mexico, or *Yerba del Indio,* is used as a local stimulant to foul ulcers. A number of species of aristolochia are employed as a remedy for *snake-bites* in various parts of the world, as *A. Serpentaria* L., in North America; *A. maxima* L. (the rhizome of which is called *Guaco* or *Contra Capitano*), in South America; *A. anguicida* L., in the Antilles; *A. brasiliensis* Mart. et Zucc.; *A. cymbifera* Mart. et Zucc.; *A. macroura* Gom.; *A. trilobata* L., etc. There is no sufficient reason for supposing that any one of them is effective.

Armeria. *Armeria vulgaris* Willd. (*Statice Armeria,* L.) *Maiden Pink.* (Fam. *Plumbaginaceæ.*)—This plant, found in Europe, Asia, and Western North America, is said to be an active diuretic. (*Ph. Post,* May, 1890.)

Arrow Poisons.—Up to the seventh century poisoned arrows were used in Europe in warfare, and they seem not to have disappeared from Spain until the sixteenth century, while poisoned daggers and poisoned swords were used even later for assassinations. The nature of the poisons employed is obscure, though it is stated that *Veratrum album,* L., and snake venom were used. The peregrinations of English and American travellers in Africa, and the various political changes and fomentations which have been the fruit of their discoveries—the war with Spain and the consequent bringing of attention to the Philippine Islands—have developed so much general interest in the wild natives of these various remote regions that we have thought it proper to prepare for our readers a general summary of what is known in regard to the poisons used by these various natives for the killing of game and the destruction of their enemies. In doing this we have thought that a geographical arrangement might well suffice. A number of arrow poisons in various parts of the world have been used to a greater or less extent as therapeutic agents, and are considered elsewhere in this work. Among these may be mentioned strophanthus, acocanthera, antiaris, and curare.

So far as our knowledge goes no poisonous arrows have ever been used in North America or in Northern Asia, unless, indeed, the statements made by Kracheninikow be correct. In the second volume of his *Vogage en Sibérie,* French edition, 1768, this traveller states that the roots of the plant known as *Zgate* are employed by several tribes living in the far north of Asia as an arrow poison, and it has been suggested, probably with insufficient reason, that the plant is an anemone. We have met with no recent author who has seen this poison. Fraser examined a poison used by the Mishmis of northeastern India and concluded it was derived from a species of aconite (*C. D.*, 1915, 40).

The *Upas tieute,* which is used in the East Indies, is said to be obtained from a climbing woody plant growing exclusively in Java, the *Strychnos Tieute* of Leschenault. This author states that a decoction of the bark of the root is concentrated to the consistence of a thin syrup, then mixed with onions, garlic, pepper, etc., and allowed to stand until it becomes clear. The poisonous principles in both *Upas antiar* and *Upas tieute,* according to Pelletier and Caventou, is strychnine combined with igasuric acid. This poison produces death by violent convulsions, the heart stopping before respiration. (Hammond, *Am. J. M. S.*, 1860, p. 363.)

It is very probable that different extracts are employed by different tribes in the islands of the Malay Archipelago. Braidwood (*Ed. M. J.*, 1864) found the arrow poison known as *Dajaksh* to be a cardiac paralyzant. It is not clear whether this is the same as Borneo arrow poison examined by Leubuscher. (*Cb. I. M.*, Bd. xvii, 1896.)

The arrow poisons used by the natives of the Philippine Islands are, according to the researches of P. C. Plugge (*A. J. P.*, 1896, ii), obtained from the *Rabelaisia philippinensis* Planch. Plugge has found in it a non-nitrogenous glucoside, *rabelaisin.* This given in very large doses produced in animals some convulsive movements, followed by profound muscular relaxation, loss of reflexes, and general paralysis, ending in death from asphyxia. On the heart it acted as an energetic stimulant, belonging to the digitalin group. (See also I. Rosenthal, *Sitzungsb. f. Physk. u. Med. Soc.*, Erlangen, 1894.)

An arrow poison is used by the Malays, under the name of *Ipoh;* it is said to be obtained from *Derris* (*Pterocarpus*) *elliptica* Benth. (Fam. *Leguminosæ*), or *tuba root,* which is much used in Java as a fish poison. It contains an active acid resin, to which the name of *derrid* has been given. Derrid appears to be one of the most powerful fish poisons known, as one five-millionth part stupefied gold fish in a few moments, and killed them within half an hour. (*P. J.*, 1890, xxi.) According to the researches of van Hasselt (*A. I. P. T.*, 1911, xxi, p. 242), closely allied, physiologically, to derrid are *pachyrhizid,* from the *Pachyrhizis angulatis,* and *nicoulin,* from the *nekoe* or *stink-wood.* These drugs are powerful poisons to the central nervous system, especially the respiratory center, and in larger doses cause slowing of the pulse by a direct action upon the heart muscle.

The natives of Perak, in the Straits Settlements, use an arrow poison stated to be a combination of aqueous extracts from the root bark of three trees, the individual extracts being known as *ipoh aker, aker lampong,* and *prual.* Ipoh aker and aker lampong are believed to be obtained from undescribed species of *Strychnos;* extracts were prepared from the root bark of these trees by Ralph Stockman (*Lab. Rep. Roy. Soc. Edinburgh,* vol. vi, 1897), and found to be of similar physiological power, each of them having a digitalis-like action and also a well marked curare-like action, causing arrest of the heart in systole and loss of power in the motor nerve endings. *Prual* is said to be made from the root bark of *Coptosapelta flavescens* Korth., now recognized as *C. macrophylla* (Roxb.) K. Sch. (Fam. *Rubiaceæ*); in the experiments of Stockman it was found to be a violent poison, very rapidly killing the muscle at the point of inoculation, and soon involving in a fatal influence the whole muscular system, so that the animal after a large dose collapsed almost at once with diastolic cardiac arrest.

The African arrow poisons are quite numerous. *Exuja* or *Echugin* is a blackish-brown, crumbly, odorless, and intensely bitter arrow poison used by the Ovambos of Southwest Africa. It is said to be yielded by an apocynaceous shrub, *Adenium Boehmianum* Schinz. From it R. Böhm (*Cb. N. W.*, 1889) isolated the crystalline glucoside ($C_5H_8O_2$), *echugin*, and a resinous body, *echugon*. The glucoside crystallizes in small, colorless, satiny, rhombic plates, easily soluble in water and alcohol, and insoluble in ether. It is present to about 10 per cent. in the crude substance, and is said to very closely resemble strophanthin in its physiological properties.

The arrow poison used by the pygmies of Central Africa has been obtained by Surgeon Parke, and is described in the *P. J.*, April, 1891. It has been found to contain two active alkaloids, *erythrophlœine* ($C_{28}H_{43}O_7N$) and *strychnine*.

The Sakayes, the Somangs, and the Wa Kamba tribes in Eastern Africa produce arrow poisons whose relations with one another are still obscure. *Hippo*, according to Laborde, causes in the lower animals vomiting, followed by tetanic convulsions and an almost simultaneous arrest of the respiration and cardiac action. (*P. J.*, July, 1887.) *Vakamba* of Laborde (*Ibid.*) is probably the same as the *ukambin* which has been studied by H. Paschkis, who found its active principle to be a crystalline body belonging to the digitalis group, and causing in the lower animals elevated blood pressure, fibrillary contractions of the muscles, and systolic arrest of the heart. (*Cb. M. W.*, 1862.)

An exceedingly bitter arrow poison, used by the tribes who inhabit the country of Segon in the French Soudan, has been examined by Ferré and Busquet (*A. de P.*, 1895, vii), who find that its active principle is a crystalline glucoside which is a very powerful muscle poison, affecting directly the heart, and producing very rapidly general paralysis, with salivation, exophthalmia, disturbance of respiration and circulation. The first influence is to increase greatly the arterial pressure. The whole action of the poison is very similar to that of strophanthin. For an investigation of South African plants by Juritz, see *P. J.*, 1906, 87.

The Australian natives, according to Lewin, (*A. E. P. P.*, 1912, lxviii, p. 333), derive an arrow poison from the *Buphane disticha* Herb. (*Hæmanthus toxicarius* L.). He found in this an alkaloid to which he gave the name of *hæmanthine*. It somewhat resembles scopolamine in its action, being both a narcotic and mydriatic, and may be the same as that described by Tutin (*Tr. Chem. Soc.*, 1911, xcix) under the name of *buphanine*. Tutin also found several other alkaloids, one of which was identified as *narcissine*.

Animal Poisons.—The use of animal arrow poisons is uncommon, though the Choco Indians, in Columbia, South America, are said to prepare a very deadly extract by holding a tree-frog, the *Hyla chocœnsis*, on a stick near a fire, and scraping off the subsequent exudate from the skin. As it is asserted that an exudate can be obtained from the skin of the ordinary European toad which is a violent heart poison, the extract employed by the Choco Indians is probably a cardiac paralyzant. Again, according to Livingstone, confirmed by Baines, some of the Bushmen prepare a poison from a cream-colored grub or caterpillar, which they term *'Nga*, said to be the first stage of the beetle *Diamphidia locusta*. The grub is gradually squeezed between the forefinger and thumb, and the colorless exudate smeared over the arrowhead. Boehm and his pupil Starcke have found this poison to be similar in its action to the snake poisons, to be dependent for its activity upon a toxic albumose, and to be non-toxic when given by the mouth. As previously stated, it is also probable that snake venom is sometimes mixed with the various vegetable poisons used by barbarians.

Natives along the Amazon River obtain an arrow poison from the venom of a toad, the *Bufo agua*. This has been examined by Abel and Macht (*J. P. Ex. T.*, 1912, iii, p. 319) who found in it 5 per cent. of epinephrine, and a neutral principle to which they gave the name *bufagin*, and assigned the formula of $C_9H_{12}O_2$. It exercises a powerful digitalis-like effect, the fatal dose for the dog being seven-tenths of a milligramme per kilo.

Arsalyt.—*Bismethylaminotetraminoarsenobenzol Hydrochloride*, $As_2(C_6H_2.NH_2.NH_2.NH.CH_3)_2.4HCl$, a yellow, water-soluble powder containing 26.5 per cent. arsenic. It has been used in *syphilis* and *malaria* (*Pharm. Ztg.*, 1915, 180), but there are not yet sufficient reports to establish its value.

Arsacetin. *Sodium Acetyl Arsanilate*, $C_6H_4(NH.CH_3CO)(AsO.OH.ONa) + 4H_2O$.—This is a compound derived from sodium arsanilate by replacing a hydrogen atom of the amino group in sodium arsanilate, with an acetyl radical. It is a white, crystalline substance, odorless and tasteless, soluble to the extent of 10 per cent. in cold and 30 per cent. in warm water. It is free from arsenous or arsenic acid, and solutions are not affected by boiling. An hour's heating in the autoclave has no action on it. One part of arsacetin in ten of water and a few drops of silver nitrate solution added will produce a pure white precipitate. Its solution, clear and colorless, should show at most a faint acid reaction. Its capability of standing thorough sterilization gives it the advantage over compounds of the same nature—like sodium arsanilate, etc.

It has been used for the treatment of *syphilis*, and although some authors have reported favorably, the trend of opinion seems to be that it is inferior, in curative value, to mercury, and that there is danger of producing optic atrophy as is seen after atoxyl. It has also been used in the treatment of *trypanosomiasis* with more or less success, but is less efficient than atoxyl. Arsacetin has been used mostly in *doses* ranging from one-half up to one and a half grains (0.03–0.1 Gm.), although some authors have employed much larger quantities.

Arsenoferratin. *Sodii Arsenoferri Albuminas.*—This is an organic compound of albumen and arsenic with ferratin. A solution of a similar composition is on the market under the name of *arsenferratose*. The latter is a brownish liquid, contains 0.3 per cent. of iron and 0.003 per cent. of arsenic. The solid form of arsenoferratin is marketed in tablets of four grains (0.25 Gm.). They are used in the treatment of *anemias*. Of the solid form 3 to 6 tablets, each containing four grains (0.25 Gm.), may be given in twenty-four hours. Of the liquid arsenferratose the *dose* is one to two teaspoonfuls three times a day.

Arsenophenyl Glycin. *Spirarsyl.*—This combination has been employed especially in the treatment of *sleeping sickness.* Zupitza and Raben (*B. K. W.*, 1910) report favorably upon it, but Scherschmidt (*D. M. W.*, 1911) finds it inferior to atoxyl; it appears to be equally dangerous. The *dose* is from eight to fifteen grains (0.5–1 Gm.) daily, for two or three consecutive days, by intramuscular injection.

Artabotrys. *Artabotrys odoratissima* (Roxb.), R. Br. (Fam. *Anonaceæ*) and *Anona uncinata* Blanco. *Ilag-ilag de China*, Sp.-Fil. *Alag-ilag Sonson*, Tag.—A decoction of the leaves of these plants is used in the Philippine Islands in the treatment of *cholera*; the overdose is said to be capable of producing abortion.

Artar Root.—This is a drug coming from the west coast of Africa, possibly the product of *Fagara Xanthoxyloides* Lam. (Fam. *Rutaceæ*), the leaves of which have been found in commercial specimens. Two alkaloids have been discovered in it by Giacosa and Nionari, one of which is said to resemble somewhat in its action veratrine, but to be a stimulant to the heart. (*Ph. Centralh.*, 1887, No. xxv.)

Artemisia frigida. Willd. *Sierra Salvia. Colorado Mountain Sage.* (Fam. *Compositæ.*)—This Rocky Mountain plant, which is found growing in immense quantities from the Saskatchewan to Western Texas, and westward, is said to be much used in that region as a diaphoretic, antiperiodic, and mild cathartic. F. A. Weiss (*A. J. P.*, 1890) found indications of a glucoside. One or two drachms (3.9 or 7.7 Gm.) of the powdered leaves, or one or two fluidrachms (3.75 or 7.5 cc.) of the *fluidextract*, may be administered in hot infusion every half hour until perspiration has set in. *Artemisia nana* Gaud., one of the North American sage brushes, is reported to yield a volatile oil, which is rich in camphor. (*P. J.*, 1910, xxxiv, 237.)

Arterenol. *Homadrenine.—Aminoethanolpyrocatechin* is a reduction product of *aminoacetopyrocatechin.* Its hydrochloride, $(OH)_2.C_6H_3.CH\text{-}OH.CH_2.NH_2.HCl$, is crystalline and slightly soluble in water. Its therapeutic uses are analogous to those of epinephrine. It is incompatible with alkalies and with ferric chloride and should be kept away from light.

Arum.—The corm of *Arum maculatum* L. (Fam. *Araceæ*), is occasionally used as a medicine in Europe. Its properties closely resemble those of *Arisæma triphyllum.* Its constituents, according to Enz, are a neutral acrid volatile principle soluble in ether, starch, gum, mucilage, sugar, lignin, albumen, saponin, fixed oil, resin, and calcium phosphate, the fresh corm containing 58.4 per cent. of water, 5.2 of lignin, and 27.2 of starch. (*A. J. P.*, xxxi.)

Arisæma triphyllum (L.) Schott. *Gouet à trois feuilles*, Fr. *Dreiblättriger Aron*, G. (Fam. *Araceæ.*) *Dragon-root, Pepper Turnip, Indian Turnip, Jack-in-the-Pulpit, Wake-robin.*—This plant is common in all parts of the United States, growing in moist shady places. The corm was formerly official. It is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state it has a peculiar odor, and is violently acrid. The acridity has been ascribed to the raphides of calcium oxalate by R. A. Weber (*J. Am. C. S.*, 1891, p. 215). This has been denied, Schneegans proving that *A. maculatum* contains saponin and Spica and Biscaro ascribe the acridity to the same principle. (*Ph. Centralh.*, 1895, p. 731.) The Indian turnip may be preserved fresh for a year, if buried in sand.

From both *Arum maculatum*, L., and *Arum italicum*, Mill., Herbert and Heim (*P. J.*, July 31, 1897) separated a saponin, also a brownish, oily, liquid alkaloid closely resembling coniine in its properties, but less active. They also found a saponin in the arum tubers.

Both the European and American arum are, in their fresh state, violent irritants to the mucous membranes, producing when chewed insupportable burning in the mouth and throat. Taken internally, this plant causes violent gastro-enteritis, which may end in death. The fresh, partially dried root has been used internally as a stimulant to the secretions, especially in *asthma, whooping cough, chronic catarrh,* and *rheumatism.* *Dose*, ten grains (0.65 Gm.), two or three times a day, increased to half a drachm (2 Gm.). The perfectly fresh root should not be used, and the fully dried root is inactive.

The corm of the European arum contains much starch, and a farina is prepared from it, in small quantities, in the Isle of Portland, on the south coast of England, and called *Portland arrow root*, or *Portland sago.* The root of *A. esculentum*, L. (more correctly *Colocasia antiquorum* Schott.), which abounds in starch, is much used by the natives of the Hawaiian and other islands of the Pacific, under the name of *taro*, as an article of food, having been previously deprived of its acridity by heat.

Asarabacca.—*Asarum europæum*, L., is an acrid, herbaceous perennial plant of the Fam. *Aristolochiaceæ*, growing in woods and shady places in Europe, Siberia and the Caucasus. The rhizome is from 2 to 3 inches in thickness, of a grayish color, quadrangular, knotted and twisted, and sometimes furnished with rootlets at each joint. It has an odor similar to that of pepper, and acrid taste, and affords a grayish powder. The leaves, which have long petioles, are kidney-shaped, entire, somewhat hairy, of a shining deep green color when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. According to Feneulle and Lassaigne, the *root* contains a concrete volatile oil (see *Asarum*), a very acrid fixed oil, a yellow substance analogous to *cystin*, starch, albumen, mucilage, citric acid, and saline matters. The root and leaves of asarabacca are powerfully emetic and cathartic, in *doses* of from thirty grains to a drachm (2.0–3.9 Gm.), but are used almost exclusively as an errhine in *headache*, and *rheumatic* affections of the face, mouth, and throat. One or two grains (0.065–0.13 Gm.), snuffed up the nostrils, produce much irritations, and a copious, persistent flow of mucus. For further information concerning this drug, see *U. S. D.*, 19th edition, p. 1400.

Asbestos.—This term is applied to several mineral substances which occur in long capillary crystals placed side by side, the whole producing a fibrous mass capable of being woven into fabrics and which possesses qualities that render asbestos very valuable in the arts. Asbestos is incombustible, insoluble, and a poor conductor of heat. It is either *hydrated magnesium silicate*, when it is known as *chrysotile*, or a compound of silicon, lime, and magnesium known as *amphibole* asbestos (for analysis, see *P. J.*, 1901, p.

575), and is found in Italy, in the Tyrol, Corsica, Savoy, in the Pyrenees, in Cornwall, Scotland, and is largely mined in Canada. For its general properties and uses, see *Ph. Rec.*, 1885, 232. In the laboratory it is used for filtering purposes, for which it is admirably adapted. It is also used as a non-conductor of heat in connection with various forms of apparatus. (See *A. J. P.*, 1883, 37; *Ph. Rund.*, 1885, 252.)

Asimina. *Asimina triloba* (L.) Dunal. (Fam. *Anonaceæ.*) *Papaw; American Papaw; Custard Apple.*—This small tree is found throughout the eastern central and southern United States as far west as Nebraska. It is chiefly notable for its edible fruit. This fruit has a very high nutritive value, weight for weight being approximately equivalent to the banana. Although there have been reported cases of mild poisoning from eating this fruit, Barbour (*J. A. M. A.*, Dec. 30, 1905) believes that these symptoms have been due to personal idiosyncrasies and not to any toxic principle in the fruit. In the fruit are imbedded a number of flat brown seeds. In these J. U. and C. G. Lloyd (*A. J. P.*, 1886) found an alkaloid, *asiminine*, which seems to have emetic properties. The bark was at one time used as a bitter. In it Fletcher could find no alkaloid but gives the principal constituents as fixed oil, 3.53 per cent.; resin, 3.43 per cent.; resin insoluble in ether, 9.5 per cent.; glucose and extractive, 8 per cent. (*A. J. P.*, 1891, 476.)

Asparagus. *Asparagus officinalis*, L. *Asperge*, Fr. *Spargel*, G. *Esparaguera*, Sp. (Fam. *Liliaceæ.*) —This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The root, which is inodorous, and of a slightly sweet taste, is used in France as a diuretic and aperient in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. In the berries H. Reinsch has found a large proportion of glucose and a yellowish-red coloring matter, *spargin.* (*A. J. P.*, xlii, 371.) From the juice of the young shoots Robiquet and Vauquelin obtained a peculiar crystallizable principle, called asparagin, which has since been found in a number of plants. (See *Althæa.*)

There is at present no sufficient reason for believing that asparagus is of value in practical medicine. The peculiar heavy odor which it imparts to the urine has been the chief foundation for the belief in its diuretic properties; but Nencki (*Provincial Med. Journ.*, March, 1891) appears to have demonstrated that this odor is due to the presence in the urine of *methyl-mercaptan,* a gas which is frequently produced in minute quantities in the intestines by the decomposition of proteids. According to Justin D. Lyle (*N. Y. M. J.*, July, 1892), eating asparagus causes the urine to answer Trommer's, Fehling's, and Böttger's glycosuria tests, although sugar is not present. Tanret found two carbohydrates, *asparagose* and *pseudo-asparagose,* in the roots and green berries of asparagus. (*P. J. Tr.*, 1909, 205.) Certain physiologists have claimed that asparagin has an effect on metabolism, but this view is probably incorrect. (See *Z. B.*, 1892, x.) Asparagus may be administered internally in the form of the syrup produced from the fresh juice or from the tincture. For further information concerning Asparagus, see *U. S. D.*, 19th edition, p. 1401–1402.

Aspirophen. *Phenaspetin Phenocoll Acetyl-salicylate.*—Under this name has been introduced a mixture of thirty-seven parts of free salicylic acid with sixty-three parts monoacetylphenocoll. It is employed as an analgesic and antirheumatic. Fackelmann (*Th. M.*, July, 1907) asserts that it is less prone to produce cinchonism than other salicylates and is more potent in controlling pain and less likely to produce sweating than aspirin. The *dose* is from eight to fifteen grains (0.5–1 Gm.).

Asplenium. *Asplenium Filix-fœmina* (L.) Bern. *Female Fern.*—The rhizome of the female fern has been supposed to possess similar vermifuge properties to that of the male fern. At present, however, it is not used, except as an occasional substitute. The vulgar name of *female fern* is also given to the *Pteris aquilina*, or *common brake,* which is further said by some authors to have the property of destroying the *tape worm.* According to Greshoff it contains a cyanogetic glucoside. The leaves of two species of *Asplenium*, *A. Trichomanes*, L., or *common spleenwort,* and *A. Adiantum-nigrum*, L., or *black spleenwort,* are mucilaginous, and have been used as substitutes for *maidenhair* (*Adiantum Capillus-Veneris* L., and *A. pedatum* L.) as pectorals, though destitute of their aromatic flavor.

Aster. *Aster puniceus*, L. (Fam. *Compositæ.*) —The aromatic astringent rootlets of this indigenous plant have been employed as a stimulating diaphoretic in *rheumatic* and *catarrhal affections.*

Asteracantha. *Asteracantha longifolia* Nees. *Ik Kirit.* (Fam. *Acanthaceæ.*)—This Indian plant is said by A. Jayesingba to be an energetic hydragogue diuretic. (*Ph. Z. R.*, Sept., 1887.)

Astrolin. *Glycopyrin Methyl-ethyl-glycolic antipyrin.* $C_5H_{10}O_3.C_{11}H_{12}ON_2$.—This is a colorless, crystalline powder, with pleasantly acidulous and faintly bitter taste, soluble in water or alcohol. It melts at 64°–65° C. and represents 61.5 per cent. of antipyrin, for which drug it is proposed as a substitute: Winzheimer finds it without deleterious influence upon the lower animals. It is suggested for the treatment of *neuralgic headaches* in *doses* of fifteen grains (1 Gm.).

Asurol. *Hydurol.*—This is asserted to be a double salt of mercuric salicylate and amido-oxy-isobutyric sodium, containing 40.3 per cent. of mercury. It is readily soluble in water. This preparation has been recommended for the hypodermic injection of mercury, especially in the treatment of *syphilis.* According to Neisser (*Th. M.*, 1909, p. 627), however, while it is rapid in its effects, it is not of itself sufficient for the cure of syphilis and should therefore be used in conjunction with some other form of mercurial treatment. The solutions should always be made with boiled distilled water, as the drug is incompatible with both carbonic acid and sodium chloride. It should be freshly prepared because on long standing a turbidity occurs, probably through the action of the carbonic acid of the air. The beginning *dose* is sixteen minims (1 cc.) of a 5 per cent. solution, which would represent one-third of a grain (0.02 Gm.) of mercury.

Atherosperma. *Atherosperma moschatum* Labill. *Australian Sassafras.* (Fam. *Monimiaceæ.*) —The bark of this tree, a native of Southern Australia, is said to have been long used by the aborigines, and later by the settlers, in *rheumatism* and in secondary *syphilis,* and has been highly commended by Greeves (*L. L.*, 1862) in acute *bronchitis.* It has been stated that both the bark and the volatile oil are powerful poisons, and Zeyer (*Vierteljahrschr. f. Pract. Pharm.*, x, 504) obtained from the drug an alkaloid, *atherospermine* ($C_{30}H_{40}O_5N_2$); see also Wittstein's *Organic Constituents of Plants*, 20. The abundant volatile oil is light yellow, and has a pleasant aromatic odor and taste, resembling those of oil of sassafras. Scott obtained from the leaves 1.7 to 2.65 per cent. of volatile oil. (*J. Chem. S.*, 101, 1912, 1612.) Ralph Stockman (*Lab. Rep. Royal Coll. Phys.*, vi, 1897) found it to resemble in its physiological action oil of sassafras and other allied volatile oils. He took repeatedly ten minims (0.6 cc.) without any pronounced effect, and one fluidrachm (3.75 cc.) given to a rabbit caused only temporary stupor, with slowing of the respiration, but not of the pulse. Three fluidrachms (11.25 cc.) caused in the rabbit marked depression of the heart and of the respiration, coma, and death in twelve hours by asphyxia.

Atoquinol. *Allyl-phenyl-cinchonine.*—This ester of phenylcinchoninic acid occurs as odorless, yellowish crystals, insoluble in water, sparingly soluble in alcohol but readily in ether and other fixed oils, with a melting point of 30° C. It appears to possess the characteristic anodyne and eliminant powers of phenylcinchoninic acid and has been used in the treatment of *rheumatism, gout, neuralgia*, etc., in doses of 0.5 to 1 Gm. (8 to 15 grains).

Atoxyl. *Sodium Arsanilate. Sodium p-aminophenylarsonate-arsamin.* $C_6H_4NH_2.(AsO.OH.ONa) + 3H_2O$.—When atoxyl was first introduced into medicine it was supposed to be *metaarsenic anilide* ($C_6H_5NHAsO_2$), but more recent studies have shown it to be sodium arsanilate. It is a white powder soluble in cold water and still more so in warm water. It has a slightly saline taste. On standing the aqueous solution assumes a yellowish tint. It contains 26 per cent. of arsenic.

There is upon the market under the name of *soamin* a substance which appears to be of precisely the same composition as atoxyl, with the exception that it contains five molecules of water instead of three. It therefore contains only 22.8 per cent. of arsenic. The physiological and therapeutic properties of these two substances are the same.

While originally introduced as a means of producing the therapeutic action of arsenic without the toxic disadvantages of that drug, atoxyl owes its notoriety to the results achieved with it by Koch in the treatment of *sleeping sickness* (*D. M. W.*, 1907, p. 200). In this highly fatal disease Koch found that the use of the drug, even in fairly advanced stages, would cause the blood to become free from trypanosomes at least temporarily. Most of the cases, however, eventually relapsed and died of the disease. When the drug was used boldly in the milder cases of the infection, occasionally a permanent cure would result. From the beneficial effects which were produced in *trypanosomiasis*, several clinicians were led to test its efficacy against the biologically allied parasite which is regarded as the causative agent of *syphilis.* While the results in the latter infection were not altogether brilliant, the preparation showed itself to exercise a distinctly toxic action upon the spirochætæ. Blumenthal (*Med. Klin.*, 1907, p. 319) and others have reported more or less favorable results from the internal administration of the drug in *cancers.* It has also been employed against *relapsing fever, malaria, pellagra, leukemia* and *frambesia* with more or less evidence of good effects.

These striking results in some of the most hopeless diseases seemed to foretell for the remedy a most important place among our therapeutic agents. Unfortunately, however, wider experience with the drug showed that it was by no means the innocent remedy which had first been believed. Although the single dose is far less toxic than an equivalent amount of arsenic, when used over long periods of time it produces degenerative changes in various portions of the central nervous system in a large proportion of cases. Igersheimer (*D. M. W.*, 1909, xxv, p. 1142) reports forty-six cases of permanent blindness due to atrophy of the optic nerve following the use of atoxyl. He has also noted in the lower animals histological changes in the brain and in the spinal cord. Schlect (*M. M. W.*, 1909, lvi, p. 971) records fatal results from four injections given on alternate days of 0.6 Gm. each. After death there was found degeneration in the internal organs such as are commonly seen after arsenical poisoning. The number of cases of blindness and even death have been so large that it would seem that the therapeutic use of the drug is scarcely justifiable except in such hopeless infections as the *sleeping sickness.* Bertrand asserts that atoxyl solutions when sterilized by heating at 120° are decomposed into sodium arsenate and aniline and therefore, sterile solutions should be prepared either by tyndalizing or filtering through a suitable clay filter. M. François examined several samples of atoxyl, which had been kept in the tropics for three to four years. Although the appearance of the product was little changed, on mixing with 10 parts of water (atoxyl is soluble in 6 parts) an opaque liquid was obtained from which a white, amorphous precipitate separated, suggesting a decomposition, into arsenous acid and sodium arsenate. Since arsenous acid is considerably more toxic than atoxyl, care should be taken in administering atoxyl which has been kept at high temperatures for any length of time. (*Pharm. Weekblad*, 1918, lv, 1472.)

It has usually been administered hypodermically in *doses* of from one to three grains (0.06–0.2 Gm.), once every other day.

Atropine Salicylate.—This salt is alleged to have advantages over the sulphate, mainly because of its more rapid and efficient action, provided it be pure and perfectly neutral. It may be prepared by Frederici's process, which is to dissolve 23 parts of atropine in pure alcohol by a gentle heat, and to add enough salicylic acid (about 18 parts) to render the solution neutral, which is determined by the use of litmus paper. The solution is carefully evaporated, and finally dried in a drying oven. It is deliquescent, and should be kept in securely stoppered vials. The *dose* is the same as that of the sulphate.

Atropine Sulphuric Acid.—This organic compound of atropine with sulphuric anhydride occurs in colorless crystals sparingly soluble in water, insoluble in most of the organic solvents, but dissolving readily in ammoniacal solutions. It has been recommended by Phillippstal (*B. K. W.*, 1913) in the treatment of *asthma* and *night sweats.* He claims that it has the advantage over atropine that it does not cause drying of the throat nor tachycardia. The *dose* he employed was one sixty-fourth of a grain (0.001 Gm.).

Azadirachta. *Azedarach, U. S.* 1860. *Pride of*

India. Pride of China. Indian Lilac Tree. Ecorce de Margousier, Fr. *Zedrachrinde,* G.—The U. S. P. formerly recognized the bark of the root of *Melia Azedarach* L. (Fam. *Meliaceæ*), a beautiful tree, thirty or forty feet high, with a trunk fifteen or twenty inches in diameter. This species of *Melia* is a native of Syria, Persia, and the north of India, and is widely cultivated. It is abundant in our southern states; north of Virginia it does not flourish. "The bark [root] is in curved pieces or quills of variable size and thickness; outer surface red-brown, with irregular, blackish, longitudinal ridges; inner surface whitish or brownish, longitudinally striate; fracture more or less fibrous; upon transverse section tangentially striate, with yellowish bast fibers; inodorous, sweetish, afterwards bitter and nauseous. If collected from old roots, the bark should be freed from the thick, rust-brown, nearly tasteless, corky layer." *U. S.*, 1880. The Br. Add. recognized under the name *Azadirachta indica* (*Neem Bark, Margosa Bark*) the bark of the stem of *Melia Azadirachta* L., or *Indian Lilac Tree.*—This contains, according to Broughton (*P. J.*, 1873, 992), a bitter amorphous resin, and a crystallizable principle, melting at 175° C. (See also *Ph. Rev.*, 1896, 231.) Cornish (*Ind. Ann. Med. Sci.*, 4, 104) had previously announced the presence of a bitter alkaloid, to which he gave the name *margosine.* It is asserted to possess antiperiodic virtues (*C. D.*, 1919, xci, 551). The bark of the trunk is "externally of a rusty-gray color, internally yellowish, and much foliated; coarsely fibrous; inodorous, bitter and slightly astringent, structure and thickness varying according to age." *Br. Add.* (For a description of the leaves and root bark, see *Ph. Rev.*, 1896, p. 231.)

Oil of Azederach is found of two kinds in Eastern Asia where it is used. One is employed for burning, the other medicinally. The latter oil, according to Lewkowitch (*Oils, Fats, Waxes,* vol. ii, p. 426), is known as *Veepa Oil, Veppam Fat* and *Neem Oil,* and has a specific gravity of 0.914, a saponification value of 196.9, and iodine value of 69.6, a Reichert-Meissel value of 1.1 and a butyro-refractometer reading of 52° at 25° C.

The decoction of azedarach is affirmed to be cathartic and emetic, and in large doses narcotic; but in a number of experiments made by H. C. Wood with extracts from the dried bark and fruit, it was found impossible to poison frogs or rabbits. Robins eating of the sweetish fruit, of which they are very fond, are often rendered so far insensible as to be picked up under the tree; though they usually recover in a few hours. Children are said to eat the fruit without inconvenience, and possibly the robins simply choke themselves with the large berries. The bark is considered, in the Southern States, an efficient anthelmintic. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the *dose* for a child is a tablespoonful every two or three hours, until it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. The fresh bark and the fruit are said to be superior as vermifuges. The Br. Add. recognized an *infusion* (*Infusum Azadirachtæ Indicæ,* Br. Add.), eighty-eight grains in a pint of cold water, *dose,* one-half to one fluidounce (15–30 cc.); also a *tincture* (*Tinctura Azadirachtæ Indicæ,* Br. Add.), two ounces in a pint of 45 per cent. alcohol, *dose,* one-half to one fluidrachm (1.8–3.75 cc.).

Baccharis. *Baccharis cordifolia* DC. *Mio Mio.*—This composite plant of Southeastern South America is notorious for its deadly effect upon sheep and cattle. Pedro N. Arata has isolated from it an alkaloid *baccharine.* (*P. J.*, x, 6.)

Balanites. *Agialida. Balanites Roxburghii* Planch. (Fam. *Zygophyllaceæ.*)—The fruit of this plant is used medicinally in India. It contains a principle closely resembling saponin. The ripe seed yield about 50 per cent. of a fixed oil (*zachun oil*), which is used for burning. (See *P. J.*, 1913, 905.) The unripe fruit is anthelmintic and purgative.

Balata. *Gum Chicle. Chicle. Tuno Gum. Leche de Popa,* Fr. *Zapota Gum.*—The term "chicle" has been applied to the dried milky juice from two distinct but related trees of the Fam. *Sapotaceæ.* The first of these, known also as *balata,* is the product of *Mimusops globosa* Gaertn., a native of the West Indies, Mexico and Central America. The crude article is solid and somewhat crumbly, of a grayish-white color with reddish-brown spots and veins; the purified article is an amorphous powder. It is an oxidized hydrocarbon, both physically and chemically related to caoutchouc and gutta percha; specific gravity 1.05; tasteless, but emitting a disagreeable odor when warmed. It has the general properties of gutta percha and Mexican chicle, being but slightly extensible, a property which fits it for use in the manufacture of chewing gum. While solid and somewhat crumbly at ordinary temperatures, it softens at 49° C. and can be molded; it is readily soluble in ether, petroleum benzine, carbon disulphide, kerosene and benzol but only slightly soluble in chloroform.

Balata is imported from Mexico, Central America and Africa in the crude form. It is the kind of chicle now most extensively used in the manufacture of the cheaper or "bubble balloon chewing gums." Balata is also used in the manufacture of transmission belts.

The second variety of chicle is that known in commerce as *Mexican Chicle* and represents the dried latex of *Achras Sapota* L. This tree, known also as the *sapodilla* or *sapota plum,* bears a sweet fruit whose flavor resembles that of the quince and is eaten by the natives of tropical America. *Mexican chicle,* also known as *loaf chicle,* occurs in irregular pinkish to reddish-brown pieces to which there is usually found adhering a considerable amount of bark and the bodies of insects. It comes entirely from Mexico. On account of the high cost of this variety of chicle, it is only used at present in the manufacture of the more expensive medicated chewing gums. For this purpose it is first purified by the following method: It is broken up into small pieces which are placed in a revolving screen-drum and washed in strong sodium hydroxide solution to remove extraneous matters. The drum and contents are then lifted out of the revolving machine and placed in a bath of sodium acid phosphate to neutralize the alkalinity.

The material is then washed with water until free from soluble salts, dried and powdered. Purified Mexican chicle occurs as an amorphous, pale pink powder, insoluble in water and the ordinary solvents, soluble in the same solvents as balata. When heated it forms a tenacious mass, which upon cooling is pink in color. On aging, it undergoes partial oxidation, becoming yellowish-brown to brown and very brittle.

Chewing gums averagely contain only about 30 to 35 per cent. of chicle, the other substances present consisting of glucose, powdered sugar, starch and flavoring. The chemical constituents of chicle have been investigated by Tschirch and Scherescheweki who found so-called resins, two of them being crystallizable *a-balaban-* and *b-balaban* and a yellow substance, *balafluavil.* (*A. Pharm.*, 1905, ccxliii, 358; see also Bosz and Cohen's investigations, *A. Pharm.*, 1912, ccl, 52; also *P. J. Tr.*, 1910, 609.) Formerly the chicles were adulterated with paraffin wax but they are now adulterated with sticks, stones and bark. The extraneous matter in Mexican chicle varies from 25 to 40 per cent.

Balsam of Gilead. *Balm of Gilead. Mecca Balsam. Balsamum Meccæ v. Judiacum. Balsamum Gileadense. Baume de la Mecque*, Fr.—The genuine balm of Gilead is the resinous juice of *Commiphora Opobalsamum* (L.) Engl. (Fam. *Burseraceæ*), a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and is still esteemed by the Eastern nations as a medicine and cosmetic. In Western Europe and in this country it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medicinal properties not existing in other balsamic or terebinthinate juices. It was formerly known as *opobalsamum*, while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum.* In this country *Poplar buds* are often, incorrectly, called Balm of Gilead Buds.

Balsam of Cativo. *Cativo Balsam.*—This substance appeared in the London market in 1902 as a substitute for copaiba. It is a balsamic resin, opaque, of a dirty light brown color and slightly bitter taste, and having an extremely adhesive quality. According to Umney, it is not soluble in 90 per cent. alcohol, but is soluble in ether and consists chiefly of acid resins with the addition of an oily substance. According to Weigel's analysis it consists of 80 per cent. of resin acids and 2 per cent. of volatile oil. It is supposed to be a product of *Prioria copaifera* Gris. (Fam. *Leguminosæ*), a large tree indigenous to Panama and Jamaica. (See *P. J.*, vol. lxix; and *Ph. Centralh.*, March, 1903.)

Balsam of Cebur or Tagulaway.—*Cebur* or *Tagulaway Balsam* is prepared in the Philippine Islands by boiling the root and twigs of *Parameria vulneraria* Radl. (Fam. *Apocynaceæ*), in cocoanut oil, so as to form a yellowish-white, oily liquid, which is used with asserted excellent results for *skin diseases* and *wounds.* (*A. Pharm.*, Nov., 1885.)

Balsam of Lagam. *Lagam Balsam.*—A thick, yellowish, fluorescent liquid, of a peculiar aromatic odor, and bitterish, acrid taste, resembling copaiba. (*A. J. P.*, 1883, p. 368.)

Balsam of Riga. *Riga Balsam. Balsamum Carpaticum. Balsamum Libam.*—This is the product of *Pinus Cembra*, L. (Fam. *Pinaceæ*), a large tree growing in the mountainous regions and northern latitudes of Europe and Siberia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odor analogous to that of the juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Kronstadt in bottles. Keller, of Darmstadt, affirms that Riga Balsam is the product of the ordinary *Pinus palustris* Mill. A similar product, called *Hungarian balsam*, is obtained in the same manner from *Pinus Pumilio* Haenke, growing on the mountains of Switzerland, Austria and Hungary.

Balsam of St. Thome. *Pan Olœo. Belam Pu.*—A balsam obtained from *Santiriopsis balsamifera* (Oliv.) Engl. (Fam. *Burseraceæ*). It is a resinous juice obtained by incisions in the trunk of the tree. It is used as a vulnerary and in diseases of the bladder and bronchi. (*Ap. Ztg.*, 1898.)

Balsam of Sulphur. *Sulphurated Oil of Linseed. Thiolinic Acid. Oleum lini sulfuratum.*—A preparation made by boiling sulphur in linseed oil. A similar preparation made from olive oil and sulphur was known in the old Edinburgh Pharmacopœia as *Oleum Sulphuratum.* It was an extremely fetid, acrid, viscid, reddish-brown fluid, which was formerly used in *pectoral complaints;* but inconvenience arose from its acrid properties, and its internal use was abandoned. It is sometimes applied as a stimulant to *foul ulcers. Haarlem Oil* is a mixture of oil of turpentine with balsam of sulphur. The *dose* is from five to thirty minims (0.3–1.8 cc.).

Balsam Wood. *Palo Balsamo.*—This is a South American wood, derived from an unknown tree, which is believed to contain *guaiacin*, and which yields to distillation nearly six parts of a thick viscous aromatic oil. This contains as its chief constituent a crystalline solid of alcoholic character, melting at 91° C. and corresponding closely to the formula $C_{14}H_{24}O$. It has found employment in perfumery. (*Schim. Rep.*, April and Oct., 1892.)

Balsamorrhiza. *Balsamorrhiza terebinthinacea* Nutt. (Fam. *Compositæ.*)—The root of this plant, obtained from Idaho and Oregon, has a strong, terebinthinate odor, and is used medicinally in the Western States. It contains volatile oil, fixed oil, resin, organic acid, and sugar (Herman T. Kelly, *D. C.*, 1897, 32).

Barbados Nuts. *Purging Nuts. Physic Nuts. Semen Ricini Majoris. Pignon d'Inde* (*des Barbades*), *Semences du Médicinier*, Fr. *Purgirnuss, Schwarze Brechnuss*, G.—These are the seeds of *Jatropha Curcas*, L. (*Curcas purgans*, Adonson) (Fam. *Euphorbiaceæ*), growing in Brazil, the West Indies, and cultivated extensively in all tropical countries. The fruit is a three-locular capsule, containing one seed in each locule, and is about the size of a walnut. The seeds are blackish, oval, 1.5 to 2 cm. long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence. They yield a fixed oil, an acrid resin, sugar, gum, a fatty acid, glutin, a free acid, and salts. A. Siegel (*Bot. Centralb.*, xlvii, 120) found in the seeds a poisonous principle, *curcin*, which he states is analogous to *ricin*, and places in the class of toxalbumins. The oil, sometimes called *jatropha oil*, may be separated by hot expression, the yield being about 40 per cent. When fresh it is without odor or color, but becomes yellowish and slightly odorous by times. Alcohol does not readily dissolve it. It is colorless, odorless, of sp. gr. 0.91 at 19° C., solidifies to buttery consistence at –8° C. Bouis believed it to be the glyceride of a peculiar acid, *isocetic acid*, but it is now considered to be a mixture of palmitin and myristin. From three to five of the *seeds*, slightly roasted and deprived of their envelopes, operate actively as a cathartic, and not infrequently produce nausea and vomiting, with a sense of burning in the stomach. The *oil* purges in the *dose* of five to ten minims (0.3–0.6 cc.), and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the *dose* of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubifacient, and the juice is said to have been usefully employed as a local remedy in *piles*. (*A. J. P.*, 1893, 335.) The seeds of *Curcas multifidus* (L.) Engl. (*Jatropha multifida* Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. (See Peckoldt, *A. Pharm.*, 1887, 415.)

Jatropha macrorhiza Benth. popularly called *Jicama*, a shrub which grows in Northern Mexico and the adjoining United States, is a purgative, acting excessively in overdose, and is believed by the Mexicans to be cholagogue. The *dose* of the fluidextract is stated to be from one-half to two fluidrachms (1.8–7.5 cc.).

J. gossypifolia Linn., of South America, is used as a local application in *leprosy* and to indolent *ulcers*, and probably has similar physiological influence to curcas. *J. urens*, L., must be excessively poisonous, as accidental contact of the wrist of a gardener in Kew with a young plant produced such symptoms that for five minutes the man was thought to be dead. (*P. J.*, April, 1872, 863.)

The roots of the *J. cardiophylla* Muell. Arg. are largely employed in Southern Arizona and Mexico for tanning purposes. According to the analysis of Josiah C. Peacock, they contain, when thoroughly dried, over 5 per cent. of tannic acid. (*A. J. P.*, 1900, 432.)

Barium. *Baryum*, Fr., G. $Ba = 137.37$.—This is the metal present in *baryta*. It was first obtained in 1808 by Sir H. Davy, who described it as a difficultly fusible metal, of a silvery-gray color, decomposing water readily; melting point 850° C., specific gravity 3.75. When exposed to the air, it instantly becomes covered with a crust of barium oxide. Barium chloride, barium dioxide, and barium carbonate were formerly official.

Barium Carbonate. $BaCO_3 = 197.37$.—It is the native carbonate, a rare mineral, discovered in 1783 by Withering, in honor of whom it is called *witherite*. It is found in Sweden and Scotland, but most abundantly in the lead mines of Northern England. It occurs usually in grayish or pale yellowish-gray, fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4.2 to 4.4. It is generally translucent, but sometimes opaque. It effervesces with acids, and, before the blow-pipe, melts into a white enamel without losing its carbon dioxide. It is distinguished from strontium carbonate, with which it is most liable to be confounded, by its greater specific gravity, and by its yielding a light greenish tint, instead of red, to the colorless flame. It is used only as a source of barium chloride whose toxic powers it possesses.

Barium Chloride. *Barii Chloridum. U. S.* 1870. *Chlorure de Baryum*, Fr. *Chlorbarium, Chlorbaryum*, G. $BaCl_2 2H_2O$.—For the method of preparing this salt, see *U. S. D.*, 19th, ed., p. 1407 (see also *Reagents*, Part III).

Barium chloride is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with bevelled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 106° C., the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol impregnated with it burns with a greenish flame. If strontium be present, an alcoholic solution of the salt will burn with a red flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates and tartrates, and the alkaline phosphates, borates, and carbonates; also by silver nitrate, mercur*ous* salts, and lead acetate. When pure it does not deliquesce. Its solution is not affected by ammonia nor by hydrogen sulphide. Tannic acid will precipitate the barium from a solution of its chloride, as tannate.

Barium chloride is actively poisonous, causing when given in sufficient doses convulsions, dilatation of the pupil, and death from respiratory failure. (For report of fatal cases see Aloy and Cournet, *J. P. C.*, 1918, xvii, 76). According to Laborde (*B. A. M.*, July, 1891), after death the blood remains of a bright red color. In smaller doses it exercises a stimulant effect upon various muscular tissues. Through its action upon the intestinal muscle it gives rise first to diarrhea and later to cramp-like spasm of both gastric and intestinal muscle. Upon the voluntary muscle it exercises an effect like that of veratrine, causing marked prolongation of the contraction; after death from barium poisoning, fibrillary contractions of the voluntary muscles may continue for a considerable period of time. It stimulates both the vascular and cardiac muscles and in sufficient dose throws the heart into permanent contraction like that produced by digitalis. In moderate dose the pulse rate is increased and the blood pressure greatly elevated. Because of its action upon the circulation it has been suggested as a cardiac stimulant in cases of *heart failure*. According to Lauder Brunton (*Practitioner*, June, 1889), the chloride is a rapidly acting heart stimulant steadying the rhythm and increasing the volume and force of the cardiac contractions. Filippi (*Lo Sperimentali*, 1907), however, asserts that the drug has such a profound influence upon metabolism that it is not suitable for medicinal purposes. It has also been used in veterinary medicine in the treatment of wind colic. A solution of barium chloride was formerly official (*Liquor Barii Chloridi, U. S.*, 1870) which contained 1 troy ounce of barium chloride in three fluidounces of water. The dose of this solution is three minims (0.2 cc.). The *dose* of barium chloride is one-half to one and a half grains (0.3–0.1 Gm.).

Barium Dioxide. *Barii Dioxidum. U. S.*, 1890. *Barium Peroxide.* $BaO_2 = 169.37$.—"Commercial, anhydrous barium dioxide. It should be kept in well-closed vessels." *U. S.*, 1890.

It is used chiefly for making hydrogen dioxide. Barium forms two oxides, BaO and BaO_2; the former is produced by the action of oxygen or dry air on barium. Barium dioxide, BaO_2, is made by heating barium oxide to about 450° C., when it takes up another atom of oxygen. It is "a heavy grayish-white or pale yellowish-white, amorphous, coarse powder, odorless and tasteless. When exposed to the air, it slowly attracts moisture and carbon dioxide, and is gradually decomposed. It is almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidely alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hydrogen dioxide, which remains in solution for a considerable time, if the reaction has taken place in the cold, and an excess of the acid is present. When heated to a bright red heat, barium dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue. It should contain at least 80 per cent. BaO_2. It is not used medicinally.

Barium Iodide. *Barii Iodidum. Iodure de Baryum*, Fr. *Jodbarium*, G. BaI_2.—This compound may be formed by double decomposition, by adding native barium carbonate in powder to a boiling solution of ferrous iodide. M. Henry, Jr., obtained it by decomposing a solution of barium sulphide with a concentrated alcoholic solution of iodine, filtering and rapidly evaporating the filtrate to dryness. Barium iodide crystallizes in small, colorless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition on exposure to the air, barium carbonate being precipitated, and iodine set free, which colors the solution. It has been used by John and Lugol, as an alterative, in *scrofulous affections* and morbid growths. The *dose* is an eighth of a grain (0.008 Gm.) three times a day, gradually increased to three grains (0.2 Gm.).

Barium Oxide or *Baryta* ($BaO = 153.37$) may be obtained from the native carbonate by intense ignition with carbonaceous matter, or from the native sulphate by ignition with charcoal, which converts it into barium sulphide, subsequent solution of the sulphide in nitric acid and strong ignition of the nitrate formed, to dissipate the acid. As thus obtained, it is an anhydrous solid, caustic, alkaline, difficultly fusible, and of a grayish-white color. Recently it has been obtained at Niagara Falls by a reaction in which, at the temperature of the electric arc, a small amount of the sulphide obtained by the reducing action of charcoal is made to react with an excess of unchanged sulphate; $3BaSO_4 + BaS = 4BaO + 4SO_2$.

Its sp. gr. is about 4. When sprinkled with water it slakes like lime, becomes hot, and is reduced to the state of a white pulverulent hydroxide. The same hydroxide is formed in mass when the anhydrous earth is made into a paste with water and exposed to a red heat in a platinum crucible. The excess of water is expelled, and the hydroxide undergoing fusion, may be poured out and allowed to congeal. Barium hydroxide dissolves in water, and forms the reagent called *baryta water*. A boiling saturated solution, as it cools, yields crystals of barium hydroxide containing eight molecules of water of crystallization.

When barium oxide is heated in a current of oxygen or air, it takes up an atom of oxygen and is changed into barium dioxide, BaO_2. When this is heated somewhat higher, it gives off the extra atom of oxygen and becomes BaO again. This power of taking up oxygen from the air and giving it up at a somewhat higher heat is now utilized on a commercial scale in the Brin process for making oxygen, and it is found that this change from BaO to BaO_2 and back again can be effected at one and the same temperature by simply heating first under pressure and then by exhausting and reducing below the normal atmospheric pressure. Barium dioxide is also of importance as the material from which hydrogen dioxide, H_2O_2, is made.

It is poisonous both because of its systemic and its local caustic action.

Barium Sulphide. *Barium Sulphidum.*—An impure form of barium sulphide is found in commerce, containing about 50 per cent. BaS_2. It is used extensively in combination with starch, powdered orris root and other diluents in depilatory mixtures. As it is sometimes abbreviated "Bar. Sulph.," the same as is applied to Barium Sulphate used in X-ray work (which see), care must be taken in dispensing it, as it has on several occasions caused death when taken internally by mistake for barium sulphate. The symptoms of poisoning by barium sulphide are practically the same as those of the chloride (See *Barium Chloride*).

Barringtonia. *Barringtonia speciosa.*—The large Indo-Malayan tree, *Barringtonia speciosa* Forst. (Fam. *Myrtaceæ*) contains, according to Maresuw, 3.3 per cent. of *barringtonin*, a colorless, amorphous glucoside, having the formula $C_{18}H_{28}O_{10}$, and belonging to the saponin group. It is said to be an active cardiac poison. (*S. W. P.*, xli, 1903, pp. 423, 435.)

Basicin. *Corticin.*—This preparation is a compound of quinine hydrochloride and caffeine. The two substances are dissolved in water. The solution is then evaporated to a high concentration and allowed to crystallize. It is employed intravenously for *malaria*, internally for *migraine, neuralgia, influenza* and similar ailments. The *dose* is three to eight grains (0.2–0.5 Gm.).

Bassia latifolia Roxb. (Fam. *Sapotaceæ*) *Mahua, Illipi Butter Tree.*—A large, deciduous tree indigenous to the forests of the central provinces of India. It possesses elliptical or oblong-elliptical leaves, bell-shaped, cream-colored flowers and reddish-yellow or orange-colored, fleshy fruits, one to two inches in length; each containing one to four seeds. Several parts of this plant have been employed in medicine and in the arts. The bark is used as an astringent and tonic and also in tanning as well as an adjunct in dyeing, where dark colors are desired. The succulent corollas of the flowers constitute a well-known Indian food. A decoction of the flowers is employed in the treatment of coughs. An infusion of the flowers is given with sugar, for the relief of thirst, and giddiness.

The greenish-yellow oil expressed from the seeds (*mahwah oil*) is used by the hill tribes in the treatment of skin diseases as well as in the manufacture of candles and soap. The cake left after the expression of the oil is employed as an emetic and detergent.

In the *B. longifolia* L., known as *mowrah* by the natives, there has been found a glucoside which was named *mowrin* by its discoverers, Moore, Baker, Young and Sawton. According to these investigators, mowrin has a digitalis-like action upon the heart and a saponin-like effect of destroying red blood cells.

Spiegel and Meyer find that crude *mowrin* is a mixture of 2 substances, the main, $C_{42}H_{68}O_{25}$, being more soluble in alcohol and yielding upon hydrolysis levulose, arabinose and *mowric* acid. This acid is also a mixture of a crystalline *mowragenic* acid, $C_{19}H_{28}O_5$, and an amorphous mowrageninic acid, $C_{19}H_{30}O_6$. Careful hydrolysis with dilute acetic acid yielded an intermediate pentoside, $C_{29}H_{50}O_{16}$ (*B. P. G.*, 1918, xxviii, 100).

The seeds are also locally known as Illipi, Illipei or Illupi nuts—they also yield about 50 per cent. of a solid fat suitable for candle making and sometimes used for food purposes.

Bassora Gum. *Karaya Gum. Caramania Gum. Hog Gum. Indian Gum. False Tragacanth. Kuteera Gum.*—Bassora gum is a collective term used to indicate a group of high-colored gums somewhat resembling tragacanth. A gum of this class came into commerce originally from the neighborhood of Bassora, on the Gulf of Persia. The soluble portion is *arabin*, and, according to Guérin constitutes 11.2 per cent. The insoluble portion consists of *bassorin*, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5.6 per cent. of ash.

The two chief Bassora gums in commerce today represent pale-colored representatives of the class and are most commonly known as *Indian Gum* and *Gum Kuteera*, respectively. *Indian Gum* is yielded by *Cochlospermum gossypium* DC. (Fam. *Bixaceæ*), a tree indigenous to southern Asia and thriving in India and adjacent countries. It occurs in inodorous rounded or vermiform tears with a rough surface and glassy fracture. If 1 Gm. of this gum be added to 50 cc. of water, an uneven mucilage forms which contains a few reddish-brown to yellowish-brown fragments. Upon stirring the mucilage separates in the form of coarse, uneven strings (distinction from Tragacanth). *Gum Kuteera* is obtained from *Sterculia urens* Roxb. (Fam. *Sterculiaceæ*), a tree indigenous to southern Asia and abundantly found in sub-Himalayan tracts from the Ganges eastward and in Persia. It occurs in inodorous yellowish-brown tears or irregular masses and swells with water. This gum has recently been found admixed with tragacanth and has not been infrequently whitened with carbonate of lead in order to disguise its presence. Bassora gums are frequently used as a filler and thickener in the manufacture of certain food products, as cheap ice creams.

Batiator Root.—The root of the *Vernonia nigritiana* Oliver and Hiern. (Fam. *Compositæ*), a widely distributed plant of West Africa, is said to be largely used in Senegal as a febrifuge, emetic, and antidysenteric, resembling ipecac somewhat in its therapeutic application. The plant is a composite which climbs to the height of a foot and a half, and yields a root composed of numerous fibers from twenty to thirty centimeters long, slender and grayish-yellow externally, a number of which are united to form an irregular knotty rhizome, unequally spherical at the neck or crown, and covered at this point with silky hairs. The active constituent is a glucoside, *vernonin*, $C_{10}H_{24}O_7$. (Heckel and Schlagdenhauffen, *A. de P.*, Aug., 1888; see also *Zeit. An. Chem.*, 1893, p. 364.) This is a hygroscopic whitish powder, forming a pale yellow solution with water, and only slightly soluble in ether and in chloroform. By the absorption of 2 molecules of water it is split into a resinous body and glucose. Physiological experiments made upon frogs show vernonin to be a cardiac poison of the digitalis group; it is also said to act as a paralyzant to the motor nerve trunks. (*P. J.*, June 30, 1888.)

Baume Tranquille. *Balsamum Tranquillans, Huile de Jusquiame Composée. Oleum Hyoscyami Compositum.*—This preparation of the French Codex consists essentially of a fixed oil holding in solution the active matters of certain narcotic and aromatic plants. According to the Codex the fresh narcotic plants, belladonna, henbane, black nightshade, poppy and stramonium, are boiled with poppy seed in a copper kettle until all their water is driven off, and a gentle heat maintained until the oil acquires a fine green color; the oil is then expressed and the essential oils of lavender, peppermint, rosemary and thyme are added. The preparation is used externally by friction as an anodyne in local pains, but especially to relieve *earache*, a few drops being placed in the ear on a pledget of cotton. The National Formulary preparation is approximately the same as the above, although a little less complex. It is known as *Oleum Hyoscyami Compositum* and consists of a solution of oils of lavender, rosemary and thyme in infused oil of hyoscyamus. (See Part III.)

Baycuru Root.—This is the root of a Brazilian plant, probably the *Statice brasiliensis* Boiss. (Fam. *Plumbaginaceæ*), which is used by the natives as a discutient in glandular swellings and as an astringent gargle. F. A. Dalpe (*A. J. P.*, 1884, xiv, 361) believed that he has found in it an alkaloid, *baycurine*, besides volatile oil, gum glucose, etc. It contains about 12.5 per cent. of tannic acid.

Bayer 205.—The composition of this substance has not been made public. It is supposed to be a derivative of amino-napthalene-sulphonic acid. It contains neither mercury nor arsenic.

Bayer 205 is a white powder, soluble in water and apparently not affected by sterilization.

Mayer (*Bull. Instit. Pasteur*, 1922, xx, p. 248), Wenyon (*B. M. J.*, 1921, ii, p. 746) and others have shown that it possesses powerful trypanocidal action. While the reports on its practical effects in human *trypanosomiasis* are not very extensive, they indicate that the drug is likely to prove one of the most efficient agents that we possess against this deadly infection. It is administered intravenously, usually in 5 per cent. solution. The beginning *dose* is 0.5 Gm. (eight grains), gradually increasing at intervals of one or two days. Muhlens and Menk (*M. M. W.*, 1921, lxviii, p. 1488) report transient albuminuria from its use.

Bdellium.—Under this name have been included various gum resins having little or nothing in common. The commercial Bdelliums are naturally divided into the Indian and the African, but E. M. Holmes, in an elaborate study (*P. J.*, lxi), recognizes five commercial varieties of African Bdellium—namely, 1. Perfumed Bdellium, which is believed to be collected in Northeastern Africa; 2. African Bdellium; 3. Opaque Bdellium; 4. Hotai Bdellium from the Somaliland, and 5. A non-aromatic acrid gum resin. *Perfumed Bdellium*, or *Habaghadi* or *bissabol*, closely resembles in appearance *Somali myrrh*, but has a less bitter, more acrid and peculiar taste which distinguishes it at once from myrrh. *African Bdellium*, proper, occurs in hard, translucent roundish pieces of a pale to dark grayish-brown color, red by transmitted light, with a resinous unstreaked fracture, dotted with glistening points. The odor is said to recall that of pepper; the taste is slightly acrid and bitter. *Opaque Bdellium* is of a pale brown color and has a bitter, slightly acrid bitter taste and a faint cedar-like odor; it occurs in tough, roundish pieces about an inch to an inch and a half in diameter. *Hotai Resin* resembles opaque bdellium, but is distinguished by its lack of odor, its slightly soapy taste, and its brittleness. These four bdelliums of Holmes are for the most part collected in Somaliland. They are the product of different species of *Commiphora*, small trees or large shrubs which suggest in appearance the English hawthorn. The species are by Holmes divided into four groups. (See *P. J.*, lxxii.) According to A. Engler, the resin of *Commiphora Roxburghiana* (Stocks) Engl. is the commercial *Gugul*, or *India Bdellium*, which is employed in the East Indies as a remedy for *leprosy*, *rheumatism*, and *syphilis*. Bdellium sometimes comes mixed with gum arabic and gum senegal. It is either in small roundish pieces, of a reddish color, semi-transparent and brittle, with a wax-like fracture, or in large irregular lumps, of a dark brownish-red color, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odor and taste like that of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odor. According to Pelletier, it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil, including loss. In medicinal properties it is analogous to myrrh, and was formerly used for the same purposes. In Europe it is still occasionally employed in plasters. The *dose* is from ten to forty grains (0.65-2.6 Gm.).

Bebeeru Bark.—*Nectandræ Cortex*, Br. 1885, is the dried bark of *Nectandra Rodiœi* Hook. (Fam. *Lauraceæ*). The *bebeeru*, *bibiru* or *sipiri*, as it has been variously named, is a tree sixty feet or more in height, growing in British Guiana and the neighboring regions of South America, and yielding the wood known as *greenheart*.

The bark occurs in large, flat, heavy pieces, from 30 to 60 cm. long, from 10 to 15 cm. broad, and about 6 mm. thick, with a short granular fracture, of a grayish-brown color on its outer surface and a dark cinnamon color on the inner. It has an intensely bitter, somewhat astringent taste. On microscopical examination it is seen to be composed chiefly of very thick-walled parenchymatous cells. The inner bark contains peculiar short, sharp-pointed, undulate bast fibers. Within the cells dark brown masses (colored greenish-black by ferrous sulphate) may be seen. Analyzed by Maclagan (1843) of Edinburgh, it was found to contain tannic acid, resin, gum, sugar, albumen, fibrin, various salts, and two alkaloids, *bebeerine* and *sepeerine*. Walz in 1860 showed that bebeerine was identical with *buxine*, obtained from *Buxus sempervirens*. This statement was confirmed by Flückiger, who proved that *pelosine* was identical with both of the above principles. (*P. J.*, *xi*, 1870, 192.) Later Maclagan and Gamgee (*P. J.*, 1869, xi) reported another alkaloid which they called *nectandrine*. Their work, however, has not been confirmed. The studies of Scholz (*A. Pharm.*, 1906, 1911 and 1914) and of Faltis (*M. Chem.*, 1912 and 1921) have demonstrated that commercial "bebeerine sulphate" is a mixture of several alkaloids as follows: *bebeerine*, $C_{18}H_{21}O_3N$, *chondrodine* ($C_{18}H_{24}O_4N$), *isobebeerine* ($C_{18}H_{19}O_3N$), *β-bebeerine* ($C_{21}H_{23}O_4N$) and *bebeerine-b* ($C_{22}H_{23}O_5N$). In the seeds, besides the foregoing principles, Maclagan found 53 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named *bebeeric acid*. The alkaloids are extracted together from the bark, in the form of impure sulphate, by a process similar to that for preparing quinine sulphate. This preparation was formerly known as the *commercial bebeerine sulphate*.

Pure bebeerine is a white, amorphous powder, whose concentrated aqueous solution is not precipitated by tartar emetic, but affords abundant white precipitates with sodium phosphate, potassium nitrate, iodide, or iodohydrargyrate, mercuric chloride, potassium platinocyanide, and nitric or iodic acid. Its acetate yields yellow amorphous precipitates with potassium ferrocyanide, potassium ferricyanide, potassium chromate, potassium dichromate, or platinum dichloride. For further information concerning these alkaloids see *Pareira*, Part I.

Nectandra is reputed to resemble cinchona in its virtues, although much inferior. It has generally been employed in the form of the impure bebeerine sulphate. In some cases of *intermittent* and *remittent fevers* it has apparently exercised a curative effect but it often fails, and cannot be relied on as a substitute for quinine. Bebeerine sulphate has been given in *dysmenorrhea*, *menorrhagia*, and *leucorrhea*. The *dose* of the commercial salt is from two to five grains (0.13–0.32 Gm.). In *malaria* from ten to thirty grains (0.65–1.9 Gm.) may be given, in divided doses, between the paroxysms.

Bedeguar. *Fungus Rosarum.*—An excrescence upon the *sweetbriar* or *eglantine*, *Rosa rubiginosa* L. and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells containing larvæ. It is nearly odorless, of slightly astringent taste and was formerly considered a diuretic and anthelmintic. *Dose*, from ten to forty grains (0.65–2.6 Gm.).

Benzanilid.—*Phenylbenzamide*, $C_6H_5NH(C_7H_5O)$, is closely related to acetanilid, containing the benzoyl radical C_7H_5O instead of the acetyl radical C_2H_3O. White to reddish, crystalline, odorless powder melting at 163° C., practically insoluble in water but soluble in alcohol. This substance has been recommended by Cahn as an antipyretic in diseases of children in *doses* of from one and a half to three grains (0.096–0.2 Gm.) for children one to three years of age; for adults the dose is ten to fifteen grains (0.65–0.9 Gm.). It has been little used.

Benzidine. *Paradiaminodiphenyl* $(C_6H_4)_2(NH_2)_2$.—A grayish-yellow crystalline powder, difficultly soluble in cold water, more readily in boiling water. This substance, especially in the form of its hydrochloride, has attained a considerable use as the means of detecting the presence of occult blood. (See *Diagnostic Tests.*)

The pharmacological properties of benzidine have been investigated by Adler (*A. E. P. P.*, 1908, lviii, p. 167) who found that large doses exercised a paralytic effect upon the central nervous system and caused the appearance of glycosuria and degeneration of the red blood corpuscles. It was oxidized in the body and eliminated as diaminodioxyphenyl.

Benzo-Iodo-Hydrine. $C_3H_5ClC_7H_5O_2$.—Prepared by mixing *benzoyl iodide* and epichlorhydrin. It forms a brown, fatty mass, soluble in ether, alcohol, and petroleum oils, insoluble in glycerin. It is decomposed at 100° C., with separation of iodine. For dispensing, it is usually mixed with powdered sugar, so that the mixture contains 3¼ per cent. of benzo-iodo-hydrine, and a teaspoonful is about the equivalent of sixteen grains of potassium iodide. It is used as a substitute for potassium iodide, because of its freedom from irritating properties and from tendency to produce iodic poisoning.

Benzo-Naphthol. *Betanaphthol Benzoate. Benzoyl-naphthol. Naphthyl Benzoate. β-Naphthyl Benzoate.* $C_6H_5COOC_{10}H_7$.—This compound is made by the action of benzoyl chloride upon β-naphthol. It is a whitish, crystalline powder, without taste or odor, melting at 110° C. and prone to darken with age. It occurs in microscopical crystals, almost odorless and tasteless, nearly insoluble in water at ordinary temperatures, more soluble in alcohol, with solubility rising rapidly with the temperature, but most soluble in chloroform. "A hot alcoholic solution should not give any cherry-red coloration when an equal volume of nitric acid and a few drops of mercuric nitrate solution are added, which would indicate the presence of free β-naphthol." This substance, which was proposed by Yvon and Berlioz (*Pract.*, Dec., 1891) as especially efficacious as an intestinal antiseptic, has been reported upon by Gilbert (*S. M.*, May, 1892), who affirms that it is of little value in *gastric fermentation*, but very valuable in *intestinal fermentation.* It is probably slowly broken up in the intestines into benzoic acid and naphthol, and the experiments made by Ewald (*B. K. W.*, 1892), indicate that it has a positive influence upon intestinal fermentation, a conclusion confirmed by various French clinicians. It appears to be free from irritant properties, and to be a very useful remedy in chronic *diarrhea;* also in *senile pruritus* dependent upon intestinal indigestion. It is best administered in small *doses* of from four to eight grains (0.26–0.5 Gm.), repeated frequently, in capsule; as much as seventy-five grains (5 Gm.) daily may be given to an adult. It is incompatible with antipyrine, camphor, phenol, ferric chloride, menthol, potassium permanganate or ethyl carbonate.

Benzosalin. $C_6H_4\left\langle\begin{matrix}O.COC_6H_5\\COOCH_3\end{matrix}\right.$ *Methyl-benzoyl Salicylate.—Benzyl-salicylic Acid Methylester.*—This compound is the methyl ester of benzoyl salicylic acid. It occurs as white, acicular crystals which melt at 85° C., insoluble in water, sparingly soluble in ether, but readily soluble in alcohol and chloroform. It is incompatible with acids or highly acid salts. This compound is asserted to pass through the stomach unchanged and be split up by the intestinal juices into its component parts, salicylic and benzoic acids, which exercise their characteristic anodyne and antirheumatic properties. It has been employed with success in the treatment of *articular* and *muscular rheumatism* and in *neuritis, neuralgia* and similar conditions where the coal tar analgesics are of service. Freund (*D. M. W.*, 1907) believes that the benzoic acid lessens the excessive sweating as well as the local irritant action produced by salicylic acid. The *dose* is eight to fifteen grains (0.5–0.9 Gm.) three or four times a day.

Benzoyl-acetyl-peroxide. *Benzozone. Benzoxate. Acetozone. Acetyl Benzyl Peroxide.* C_6H_5-$CO.O.O.CH_3CO$.—The pure peroxide forms a white, crystalline mass melting at 36.6° C. When gradually heated it slowly decomposes and evaporates; if suddenly heated it almost instantly decomposes and in a tightly-stoppered bottle an explosion will follow. Grinding, compressing, or pounding the undiluted substance will often bring about the same result. In crystalline form, the substance is soluble in oils to the extent of about 5 per cent., slightly soluble in alcohol, moderately soluble in ether, chloroform, and carbon tetrachloride, although gradually decomposed by all the solvents with the exception of neutral petroleum oils. It is decomposed by contact with alkaloids and organic matter of all kinds. It is slowly hydrolyzed and decomposed by water. Acetozone of the markets is benzoyl-acetyl-peroxide diluted with a neutral drying powder so that 50 per cent. of the pure article is represented. Benzoyl-acetyl-peroxide is moderately soluble in water so that fifteen grains of it may be dissolved in one-half gallon of boiled or distilled water; the solution should be used within thirty-six hours after it is made. If the commercial drug be employed, thirty grains may be used in the half gallon; the solution should be allowed to settle and be decanted without filtration. A mixture of acetyl-benzoyl-peroxide and chlorbutanol (chloretone) in liquid petrolatum is known as *acetozone inhalant.*

Benzoyl-acetyl-peroxide is a very active germicide. Experiments in the laboratories of the United States Government in the Philippines show that 1 part of the hydrolyzed substance to 177 of water, and containing only 0.05 per cent. of active oxygen, destroys all germs, including spores, almost instantly; even at a dilution of 1 in 3000, vegetating germs, as a rule, are killed within one minute, but the spores require an appreciable time. It was further shown that 1 part in 1000 absolutely destroys and that 1 in 30,000 distinctly inhibits the growth of the comma bacillus. In the experiments of Ferer and Novy (*Am. Chem. J.*, 1902, xxvii, No. 3), one drachm (3.9 Gm.) of it a day, given for several weeks to a dog weighing eight kilos, produced no sensible effect. Charles L. Bliss has shown that acetozone is eliminated in the form of hippuric acid. In internal medicine benzoyl-acetyl-peroxide has been used in the United States hospitals with most excellent results in the treatment of *cholera*, given in double capsules in *doses* of from three to five grains (0.2–0.32 Gm.) every two to four hours. It was found that when the stomach was full at the time of administration vomiting frequently occurred, probably being due to the decomposition of the peroxide by the organic matter present, since no irritation was produced when the stomach was empty. Benzoyl-acetyl-peroxide has been employed by Wasdin, and subsequently by Harriss and others (*T. G.*, 1902–1903), in *typhoid fever* with alleged most extraordinary results in the reduction of the local and general symptoms—one hundred and thirty to two hundred and ten grains (8.3–13.6 Gm.) being administered in the twenty-four hours. Acetozone has also been employed locally as a germicide in *gonorrhea, malignant edema, tinea tonsurans, infected ulcers,* and similar affections. In surgical cases acetozone may be applied directly to the wound. When used as an intestinal antiseptic in typhoid fever or in conditions similar to those resulting from this disease, a 1 in 1000 solution should be freshly prepared each day, and administered almost *ad libitum.*

Benzoyl-Eugenol.—*Benzeugenol,* $C_{10}H_{11}(C_7H_5O)O_2$, occurs in colorless prisms or crystals, melting at 70.5° C., soluble in alcohol, ether, and chloroform, insoluble in water. It is similar in its properties and medicinal uses to *cinnamyleugenol,*

$C_{19}H_{18}O_3$. Both are used as antiseptics and in the treatment of *tuberculosis.*

Benzoyl Superoxide. *Benzoyl Peroxide. Lucidol.* $C_6H_5.CO.O.O.CO.C_6H_5$.—Sodium peroxide and benzoyl chloride are dissolved in water and heated. The resulting product is filtered and the crystals in the filter are washed with warm alcohol. The crystals of benzoyl superoxide are lustrous, white and prismatic, almost insoluble in water but a little more soluble in alcohol. According to Loevenhart (*Th. M.*, 1905, p. 426), it exercises a more powerful oxidizing effect than even hydrogen peroxide. When locally applied it is non-irritant. He recommends it as an antiseptic and analgesic application, either used pure in the form of a dusting powder, or in the form of a 10 per cent. ointment in *burns* and *skin diseases.*

Benzoyl Tropeine, $C_{15}H_{19}O_2N + 2H_2O$, is formed by heating tropine with benzoic and dilute hydrochloric acids to 100° C., when the benzoyl radical, C_7H_5O, derived from benzoic acid, C_6H_5-CO.OH, replaces a hydrogen atom of the tropine, $C_8H_{15}NO$, and $C_8H_{14}(C_7H_5O)ON$ is produced. It forms silky needles, fusing at 58° C. When deprived of water, the anhydrous base fuses at from 41°–42° C., and can be sublimed without decomposition. It has a strong basic reaction, and its salts are not very stable.

Filehne (*B. K. W.*, vii, 1887) has found that benzoyl tropeine is a powerful local anesthetic, also affecting the pupil and accommodation like other tropeines. He also found other benzoyl compounds to be local anesthetics, *benzoyl methyltriacetonalkamine* being the most powerful, *benzoyl quinine* next, *benzoyl morphine* the least.

Benzyl Alcohol, $C_6H_5CH_2OH$, *Alcohol Benzylicum.*—This has been brought forward by Macht (*J. P. Ex. T.*, 1918, xi, and *J. A. M. A.*, October 30, 1920) as a local anesthetic. The experiments of Sollmann (*J. P. Ex. T.*, 1919, xiii, p. 355) show, however, that although when applied to the cornea it is approximately equal to beta-eucain in power, it has little action upon mucous membranes of the mouth or nose and that it is sufficiently locally irritant to seriously interfere with its usefulness. Solutions even in sealed ampules are likely to undergo decomposition.

Benzyl Benzoate. *N. N. R.*, 1924. *Benzylis Benzoas,* $C_6H_5COO.CH_2C_6H_5$.—Benzyl benzoate is an ester of benzyl alcohol and benzoic acid. It occurs naturally in some of the balsamic resins either alone or in combination with related compounds. Cinnamein is said to consist mainly of this compound. It is a constituent in the delicate fragrant perfumes of hyacinth, gardenia, jasmin, tuberose, and orange blossom.

It may be prepared by fractionation of Peru balsam or synthetically by one of the following methods: 1. By the action of sodium and benzaldehyde. 2. By treating nitroso-benzoyl-benzylamin with alcohol. 3. By acting upon benzaldehyde with sodium hydroxide.

Benzyl benzoate is a colorless oily liquid with a faint odor and a sharp pungent taste, insoluble in water or glycerine, but miscible with alcohol, chloroform or ether. It boils at from 320° to 325° C. with partial decomposition; has a specific gravity of 1.08 to 1.12 at 25° C. and is inflammable. It is neutral to litmus and is decomposed by an alcoholic solution of potassium hydroxide.

The addition of powdered soap to the alcoholic solution of benzyl benzoate makes it miscible with water, the soap acting as an emulsifying agent.

The introduction of this compound into medicine is due to the physiological studies of Macht (*J. P. Ex. T.*, 1918, xi, 419) who found that the benzyl nucleus exercised a paralyzing effect upon unstriped muscle tissue. He experimented with both the benzoate and acetate of benzyl, but the latter was found to produce too much disturbance of the stomach to be clinically useful. Through its influence upon the muscle tissue, benzyl benzoate causes relaxation of the intestines, ureters, bronchi, etc. It also produces a fall in the blood pressure by relaxation of the arterial muscles. Upon the heart itself it exercises practically no effect except in large doses, when it seems to have a slightly stimulant action. It is largely broken up in the system, and appears in the urine as hippuric acid.

Benzyl benzoate has been used clinically for the purpose of lessening spasm of various unstriped muscles, as in *biliary colic, renal colic, intestinal spasms* of various type, *dysmenorrhea, asthma,* etc. It has also been used in cases of high blood pressure, whether due to arterial spasm or secondary to chronic *nephritis.* According to the investigations of Macht, in the latter group of cases it exercises no injurious effects upon the kidneys. Babcock (*J. A. M. A.*, 1924, lxxxii, 193) tried it in *angina pectoris* with complete relief from the pain in a certain proportion of cases, but no benefit in others. Despite the early enthusiastic commendations concerning this drug, it has not justified the high hopes to which it gave rise. Mason and Pieck (*J. Lab. Clin. M.*, 1920, vi, 62) were unable to demonstrate any relaxing effect upon the various unstriped muscles from the intravenous injection into dogs, and Gruber and Shackelford (*J. Lab. Clin. M.*, 1924, ix, 685) found that in doses up to 30 drops it failed to lower the blood pressure in human beings.

The dose ordinarily recommended for benzyl benzoate is from 3 to 6 minims (0.18 to 0.37 c.c.). It is most commonly exhibited in the form of a 20 per cent. alcoholic solution, of which 15 to 30 minims, well diluted with water, may be given at a dose. In some cases it produces so much disturbance of digestion as to greatly interfere with its use.

Benzyl Mandelate.—This compound was suggested by Macht (*J. P. Ex. T.*, 1923, xxi, p. 443), on the ground that both mandelic acid and benzyl derivatives are depressant to the involuntary muscle. It occurs as colorless crystals practically insoluble in water but soluble in alcohol. His experiments on both the lower animals and human beings show a marked effect in relaxation of the spasms of the involuntary muscles, especially in lowering blood pressure.

Benzyl-Sodium Succinate. *Sodium-benzyl succinate* (*Benzycin*) and *sodium-dibenzyl phosphate* (*Benzyphos*).—Both of these salts occur as white powders freely soluble in water, the former represent 39.5 per cent. of benzyl and benzyphos 60.7 per cent. They are stated to exercise the characteristic physiological effects of the benzyl derivatives on unstriped muscle. (See *Benzyl Benzoate.*) The recommended dose is from five to fifteen grains (0.3 to 1.0 Gm.).

Benzyl Succinate. *Benzylis Succinas. Dibenzyl Succinate N. N. R.*, 1924.—Esterol, $C_6H_5CH_2.OOC.$-$CH_2.CH_2.COO.CH_2C_6H_5 = C_{18}H_{18}O_4$.—This compound occurs in the form of white or pale yellowish crystals, practically tasteless and odorless, insoluble in water but soluble in alcohol and is asserted to be non-irritant to the stomach. It is recommended in the treatment of *dysmenorrhea, asthma, high blood pressure, colic* and similar spasmodic conditions in which benzyl benzoate has been used; the advantage is claimed for it that it does not nauseate. The *dose* is 5 to 10 grains (0.3 to 0.6 Gm.) three or four times a day usually administered in tablet form.

Betaine.—This is an alkaloid of weak basic properties which Scheibler discovered in the juice of the sugar beet. (*A. J. P.*, xli, 559.) Husemann showed it to be identical with *lycine*, and to have the composition $C_5H_{11}NO_2$. (*A. J. P.*, 1875, 209.) Liebreich also obtained it by the oxidation of choline, and called it *oxyneurine*. (*Ber. d. Chem. Ges.*, iv, 735.) It has been made synthetically, and its relation to choline and similar compounds established. It belongs in the series of organic compounds of which choline is the alcohol and muscarine the aldehyde. It is now known to be *trimethyl glycocoll*,

$$\begin{array}{l} CH_2.N(CH_3)_3 \\ | \quad / \\ COO \end{array}$$

.

It is prepared by patented processes from beet sugar molasses after the separation of other crystallizable bodies. In plants it is not a nitrogen reserve but is used up by the plant, during its development. It may also be looked upon as the anhydride of hydroxy-trimethyl-amino-acetic acid.

Waller and Plimmer (*P. J.*, lxxi, 517) find that betaine is feebly but distinctly toxic. In dose of 0.1 Gm. per kilo it produced in rabbits fall of blood pressure with final paralysis of the heart. They assert that pure betaine is less poisonous than the commercial. Boger and Josué (*S. M.*, 1898) believe that they have shown that betaine is capable of neutralizing tetanus toxin. Pelicaut (*Press. Med.*, 1904, p. 485) has recorded one case of recovery in which the alkaloid was used in *doses* of eight grains (0.5 Gm.) hypodermically twice a day. Since, however, both chloral and antitoxin were employed in this case, it is doubtful whether the favorable results were due to the betaine.

Betaine Hydrochloride. N. N. R., 1924. *Acidol. Lycine hydrochloride.* $C_5H_{11}NO_2HCl$.—It is prepared by the action of hydrochloric acid on betaine and consists of colorless crystals, freely soluble in water, and contains 23.8 per cent. absolute hydrochloric acid. When dissolved in water it gradually liberates the acid, and has been used by Flatow (*D. M. W.*, 1905) and others as a substitute for hydrochloric acid in *gastric indigestion. Dose*, eight grains (0.5 Gm.).

Beta-Naphtholsulphonic Acid. *Acidum Betanaphtholinsulphonicum.* $C_{10}H_6(OH).SO_3H$.—Betanaphtholinsulphonic acid occurs in white pearly scales, tinged with red. It is readily soluble in water and alcohol, and is of medical interest as a test for albumin in the urine. According to E. Riegler, the reaction is so delicate that it will make plainly visible the presence of one part of albumin in forty thousand of water. Albumoses and peptones are also thrown down, but such precipitates disappear on the application of heat, which does not occur with albumin. *Riegler's test* is best performed by adding from twenty to thirty drops of a 5 per cent. aqueous solution of the reagent to five or six milliliters of the urine.

Betol. *Naphthalol. Naphthosalol. Salinaphthol. Salicylic-naphthyl ester. Betanaphthyl Salicylate. Naphthyl Salicylate. Salicylic Acid Ester of β-Naphthol.* $C_6H_4OH.CO.O.(C_{10}H_7)$.—Betol occurs in white, shining crystals, is odorless and tasteless, melts at 95° C., and is insoluble in cold water or hot water, soluble in cold alcohol with difficulty, but readily dissolves in hot alcohol (1 in 3), in ether, and in benzene. It is not decomposed by acids or alkalies in the cold, but the alkaline pancreatic fluid has the power to decompose it into β-naphthol and salicylic acid.

Betol was proposed by Sahli as a substitute for salol, on the ground of its being less disagreeable and yielding in the intestines naphthol instead of the more poisonous phenol. It contains, however, 10 per cent. less salicylic acid than does salol, and, having a much higher melting point, splits up much less readily in the intestines; a fact which gains importance from the observation that frequently salicylic acid cannot be found in the urine after its ingestion. Sahli has given as much as one hundred and eighty grains (11.6 Gm.) in twenty-four hours. Betol may be used in *rheumatism*, and is especially commended by Kobert in ammoniacal *cystitis*. Butter of cacao will dissolve one-fourth of its weight of betol, so that suppositories or bougies are readily made. *Dose*, four to eight grains (0.26–0.5 Gm.).

The *salicylic ester of a-naphthol*, an isomer of betol, is known as *alphol*. It is also said to resemble salol in therapeutic effect. The *dose* is from eight to fifteen grains (0.5–1.0 Gm.).

Betonica. *Betonica officinalis*, L. *Wood Betony.*—A perennial European labiate herb, feebly aromatic and astringent. Its root has been considered emetic and purgative.

Betula. *Betula alba* L. *Paper*, or *European White Birch. Bouleau*, Fr. *Birke*, G. (Fam. *Betulaceæ.*)—Various parts of this tree have been applied to medicinal uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with alkalies, is said to produce the effects of a tonic laxative. (*J. P. C.*, xxvi, 208.) The *inner bark*, which is bitterish and astringent, has been employed in *intermittent fever*. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and applied to various economical uses. The bark contains *betulin*, or *betula camphor*, which Hausemann (*Ann. Ch. Ph.*, clxxxii, 368) has shown to be a diatomic alcohol, as it forms a diacetate. Its formula is $C_{36}H_{60}O_3$, fusing point 258° C. When oxidized it yields *betulinic acid*, $C_{36}H_{54}O_6$, and *betulinamaric acid*, $C_{36}H_{52}O_{16}$. When the bark is distilled, it yields an empyreumatic oil called *oleum rusci*. (See *Oleum Betulæ Empyreumaticum Rectificatum.*)

The *leaves* of birch, which have a peculiar, aromatic, agreeable odor, and a bitter taste, have been employed, in the form of infusion, in *gout, rheumatism*, and *dropsy*. Active diuretic properties are claimed for birch leaves and attributed to the *betuloretinic acid* in them. An alcoholic extract has been used in daily *doses* of from twenty-five to fifty grains (1.6–3.2 Gm.). When the stem of the tree is wounded a saccharine *juice* flows out which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it in some parts of Europe. *Tinctura Rusci* is made, according to Hager, as follows: Ol. Rusci 10, Alcohol, Æther, of each 15, Ol. Lavandule, Ol. Rosmarini, Ol. Rutæ, of each 0.4 part; filter. (*A. J. P.*, 1881.)

Betula lenta L., popularly known as *sweet birch* or *black birch,* is an indigenous tree with a dark brown, close bark with much less tendency to separate into lamina than the other birches. The wood is rose-colored, fine grained, and highly esteemed for cabinet work. The bark of this tree owes its sweet odor to methyl salicylate and is an important commercial source of natural "oil of wintergreen" (see *Oleum Gaultheriæ*).

Bezoar.—This name has been given to concretions formed in the stomach or intestines of animals, which were formerly thought to possess extraordinary medicinal virtues. Many varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar* (*lapis bezoar orientalis*), and the *western bezoar* (*lapis bezoar occidentalis*); the former was most esteemed. The bezoars are essentially impure calcium phosphate, except in the vegetable bezoars where the concretions are made up of plant hairs.

Bidens. *Bidens bipinnata,* L. *Spanish Needles.*—An indigenous composite plant, of which the root and seeds are popularly used as emmenagogues, and by the eclectics in *laryngeal* and *bronchial diseases.*

Bird-Lime. *Bird-glue. Vogelleim,* G.—A viscid substance, existing in various plants, particularly in the bark of *Viscum album* L. (mistletoe), and *Ilex Aquifolium* L., or *European holly,* from the latter of which it is usually procured. Large quantities are made in Japan from *I. crenata* Thunb., *I. othera* Spreng. and *I. latifolia* Thunb. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing the latter in proper vessels in a cool situation, where it is allowed to remain till it thickens, when it is washed to separate impurities. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odor analogous to that of flaxseed oil. Exposed to the air, in thin layers it becomes dry, brown, and pulverizable, but reacquires its viscidity upon the addition of water. It is a complex body, but is thought to owe its characteristic properties to a proximate principle, which is called *glu* by the French chemists. This principle is without odor or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to Macaire, it is insoluble in the fixed oils, either hot or cold, a property which distinguishes it from the resins. Macaire proposed for it the name of *viscin* (*J. P. C.*, xx, 18.) Its analysis corresponds to the formula $C_{20}H_{48}O_8$ (or possibly $C_{20}H_{32} + 8H_2O$). After the extraction of the viscin by ether, Reinsch found a substance soluble in oil of turpentine which he called *viscaoutchin,* because of its elastic caoutchouc-like character. He gives it the formula $C_8H_{16}O$. Bird-lime is so tenacious that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

Under the name of *viscum aucuparium verum,* or *viscin,* bird-lime has become a commercial substance which, when dissolved in benzene, gives a syrupy, intensely green solution capable of any degree of concentration, and possesses extraordinary adhesive powers, adapting it for use as the basis of plasters and also as a vehicle for various dermatological remedies. The ordinary base of *viscin plasters,* as proposed by Riehl, consists of a mixture of 1500 Gm. of solution of viscin, 100 Gm. of powdered orris, 400 Gm. of starch, to which are added 280 Gm. of Venice turpentine, and 31 Gm. of Dammar gum, the whole reduced to a paste by evaporation. In the preparation of salicylic viscin plasters the same formula is followed, excepting that the last two substances are replaced by 5 to 10 per cent. of salicylic acid. Various viscin plasters are made with mercury, iodoform, and other active substances. *Zincum viscosum* is a viscin solution of the consistency of linseed oil, containing 10 per cent. of zinc oxide. For medicinal properties of mistletoe, see *Viscum.*

Bismal. $4C_{15}H_{12}O_{10} + 3Bi(OH)_3$.—The bismuth salt of methylene-digallic acid. A grayish-brown powder, insoluble in water or the gastric juice, but soluble in alkaline solutions. It is used as an astringent in *diarrhea,* especially in prolonged cases that are not benefited by opium treatment. The color of this compound becomes darker with age and is found to vary from yellow to dark brown. *Dose,* from one and one-half to five grains (0.096–0.32 Gm.).

Bismon. *Colloidal Bismuth Oxide.*—A substance said to be produced by the reaction between bismuth salts and alkaline solutions of sodium lysalbinate or protalbinate. It occurs as a translucent amorphous mass, containing 22.3 per cent. of bismuth oxide; freely soluble in warm or cold water, the solution up to 25 per cent. being a reddish-yellow and slightly opalescent tasteless fluid; when stronger, syrupy or gelatinous. It has been highly recommended in the treatment of *gastro-intestinal catarrh,* especially in infants. It cannot be used hypodermically on account of its tendency to produce local disturbances and nephritis. Eighty minims (5 cc.) of a 10 per cent. aqueous solution may be given three or four times a day to young children, and *doses* of fifteen grains (1 Gm.) are said to be borne without difficulty by older children; always given in solution and not in powder.

Bismuth Albuminate. *Bismuthi Albuminas. Bismuthum Albuminatum. Wismutalbuminat,* G. *Bismuthose.*—A compound of indefinite composition made by adding a solution of 75 parts of dried egg-albumin to 25 parts of bismuth and ammonium citrate dissolved in a small quantity of water and drying the product at a low temperature.

A pale gray or white powder, not wholly soluble in water, containing from 10 to 12 per cent. of bismuth. It is used in gastric and intestinal cramps in *doses* of from eight to fifteen grains (0.5–1.0 Gm.).

Bismuth and Ammonium Citrate.—*Bismuthi et Ammonii Citras, U. S. IX; Bismuthi Ammoniocitras; Bismuthum Citricum Ammoniatum; Citrate of Bismuth and Ammonium; Citrate de Bismuth et d'Ammoniaque,* Fr.; *Citronensaures Wismutoxyd-Ammonium; Wismutammoncitrat,* G. —"Bismuth citrate rendered soluble by the presence of ammonium citrate; when dried to constant weight in a desiccator over sulphuric acid, it yields, upon ignition, not less than 46 per cent. nor more than 52 per cent. of bismuth oxide [Bi_2O_3]." *U. S. IX.* The process of the *U. S. VIII* was as follows.

"Bismuth Citrate, *one hundred grammes,* Ammonia Water, Distilled Water, each, *a sufficient quantity.* Mix the Bismuth Citrate with *two hundred cc.* of Distilled Water and rub it to a smooth paste, heat the mixture on a water-bath, and gradually add Ammonia Water until the salt is dissolved and the liquid is neutral or has only a faintly alkaline reaction. Then filter the solution, evaporate it on a water-bath to a syrupy consistence, and spread it upon plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in amber-colored, well-stoppered bottles, protected from light." *U. S. VIII.*

The Br. Pharm., 1914, gives a process for a solution in which bismuth citrate is produced. (See *Liquor Bismuthi et Ammoniæ Citratis*, Br.)

The U. S. Pharmacopœia described it as in "shining, pearly or translucent scales, or white powder, becoming opaque with loss of ammonia on exposure to the air; it is odorless and has a metallic taste. Bismuth and Ammonium Citrate is very soluble in water and sparingly soluble in alcohol. When strongly heated, the Bismuth and Ammonium Citrate fuses and finally leaves a blackened residue, having a yellow surface. A solution of this residue in a slight excess of nitric or hydrochloric acid produces a white turbidity when added to 25 volumes of distilled water. An aqueous solution of Bismuth and Ammonium Citrate (1 in 20) is neutral or faintly acid to litmus. Ammonia is evolved when Bismuth and Ammonium Citrate is boiled with a slight excess of sodium hydroxide T.S. An aqueous solution of the Bismuth and Ammonium Citrate, when treated with an excess of hydrogen sulphide, yields a black precipitate. The filtrate from the latter, when deprived by heat of the excess of hydrogen sulphide and boiled with an excess of lime water, yields a white precipitate. Dissolve about 0.05 Gm. of Bismuth and Ammonium Citrate in 1 mil of distilled water, in a test tube, add 5 mils of sulphuric acid (free from nitrous compounds), cool the mixture and carefully pour over it 5 mils of ferrous sulphate T.S without mixing; no red or brown zone appears immediately (*nitrate*). Dissolve 1 Gm. of Bismuth and Ammonium Citrate in 50 mils of distilled water, precipitate the bismuth completely with hydrogen sulphide, filter, evaporate the filtrate to dryness and ignite. The weight of the residue does not exceed 0.005 Gm. (*alkalies or alkali earths*). Ignite 3 Gm. of the Bismuth and Ammonium Citrate, dissolve the residue in just a sufficient quantity of warm nitric acid, and pour the solution into 100 mils of distilled water; a white precipitate is produced. Filter this mixture, evaporate the filtrate on a water-bath to 30 mils, again filter the liquid and divide the new filtrate into portions of 5 mils each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas.* The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth and Ammonium Citrate, as described in the following test, does not respond to Bettendorf's Test for arsenic.

"*Assay.*—Take about 1 Gm. of Bismuth and Ammonium Citrate, previously dried to constant weight in a desiccator over sulphuric acid, and weigh accurately. Ignite it in a porcelain crucible and, after cooling, add 5 mils of nitric acid to the residue, drop by drop, warming until solution is effected. Evaporate this solution to dryness, and carefully ignite it at red heat. It leaves a residue of bismuth oxide (Bi_2O_3) corresponding to not less than 46 per cent. nor more than 52 per cent. of the original weight of Bismuth and Ammonium Citrate taken." *U. S. IX.*

As frequently seen in commerce it is not entirely soluble in water; this is due to the loss of ammonia through exposure, and a few drops of ammonia water added to the turbid solution are generally sufficient to restore its transparency.

This salt, because of its solubility, lacks the therapeutic virtues of the official preparations of bismuth. It is actively astringent, and more irritant in its action. It is occasionally of service in *serous diarrheas*, but should not be used when there is much inflammation.

Dose, one to three grains (0.065–0.20 Gm.).

Bismuth Benzoate. $Bi(C_7H_5O_2)_3$. *Bismuthi Benzoas.*—It is a white powder, insoluble in water, made by double decomposition between bismuth nitrate and sodium benzoate. It contains about 65 per cent. of bismuth, and may be given as an intestinal antiseptic in *diarrheas*, in *doses* of from eight to fifteen grains (0.5–1.0 Gm.) four to six times a day. It has been commended by Finger as a substitute for iodoform.

Bismuth Betanaphtholate. *Bismuthi Betanaphtholas U. S. IX. Orphol.*—"A compound of bismuth and betanaphthol of somewhat varying composition, yielding not less than 15 per cent. of betanaphthol [$C_{10}H_7OH$] and, upon ignition, not less than 73 per cent. nor more than 78 per cent. of bismuth oxide [Bi_2O_3]." *U. S. IX.*

This compound has been dismissed from the U. S. P. IX. It is obtained by precipitating solution of sodium betanaphtholate with an acetic acid solution of bismuth nitrate with the addition of solution of sodium hydroxide. It was officially described as "a buff-colored to grayish-brown, amorphous powder; odorless or having a faint odor of betanaphthol; tasteless; permanent in the air. Bismuth Betanaphthol is nearly insoluble in water, alcohol, chloroform or ether; partially dissolved by mineral acids with the formation of the corresponding bismuth salts and the liberation of betanaphtol. When strongly heated Bismuth Betanaphthol chars and finally leaves a grayish-yellow residue, which is blackened by hydrogen sulphide T.S. Shake about 1 Gm. of Bismuth Betanaphthol, accurately weighed, with 20 mils of chloroform, filter the mixture, allow the filtrate to evaporate spontaneously and dry the residue in a desiccator over sulphuric acid; the weight of this residue does not exceed 1 per cent. (*free betanaphthol*). Shake about 0.5 Gm. of Bismuth Betanaphthol with 10 mils of distilled water and filter; the filtrate is colorless and neutral to litmus. Heat gently a mixture of about 0.2 Gm. of Bismuth Betanaphthol with 5 mils of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire; the vapors evolved do not turn red litmus blue (*nitrates*). Incinerate about 2 Gm. of Bismuth Betanaphthol in a porcelain crucible, cool the residue and add just sufficient nitric acid to form a solution with the aid of heat. This solution, when poured into 100 mils of distilled water, produces a white, crystalline precipitate. Now filter the mixture, evaporate the filtrate to 30 mils and again filter if not clear; the clear filtrate does not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas.* The bismuth oxide obtained in the following assay does not respond to Bettendorf's Test for arsenic.

"*Assay for Betanaphthol.*—Dissolve about 2 Gm. of Bismuth Betanaphthol, accurately weighed, in 20 mils of hydrochloric acid with the aid of heat, cool the liquid and then shake it in a separator with successive portions of chloroform until the extraction of the betanaphthol is complete. Combine the chloroform solutions, allow the liquid to evaporate spontaneously and dry the residue in a desiccator; the weight of the residue corresponds to not less than 15 per cent. of the weight of Bisumth Betanaphthol taken. This residue, crystallized from a solution in boiling distilled water, responds to the tests for identity under *Betanaphthol.*

"*Assay for Bismuth Oxide.*—Incinerate about 2 Gm. of Bismuth Betanaphthol, accurately weighed, in a porcelain crucible, cool the residue and dissolve it in nitric acid. Evaporate the solution to dryness and carefully ignite the residue until of constant weight; the bismuth oxide (Bi_2O_3) so obtained corresponds to not less than 73 per cent. nor more than 78 per cent. of the original weight of the Bismuth Betanaphthol taken." *U. S. IX.*

This salt of bismuth is employed especially in the treatment of *enteritis* on the supposition that when the salt is broken up in the intestinal tract it will liberate betanaphthol, and therefore exercise a more powerful antiseptic action than the other salts of bismuth.

Dose, from five to twenty grains (0.32–1.3 Gm.).

Bismuth Borate.—*Bismuthi Boras*, $BiBO_3$, is a grayish-white powder which has been used as an intestinal antiseptic in *doses* of from seven to fifteen grains (0.45–1.0 Gm.).

Bismuth Borophenate.—*Bismuthi Borophenas, Markasol*, has been recommended as a slightly astringent absorbent powder, to be used in the same way and for the same purposes as iodoform. It is free from odor, and is alleged to be locally antiseptic.

Bismuth Carbolate. *Phenol Bismuth*, $Bi(OH)_2(C_6H_5O)$.—A white, non-irritant, and non-toxic powder, almost odorless and tasteless, which, according to its manufacturer, contains 80 per cent. of bismuth in chemical combination with 19 per cent. of phenol. It is stated by M. F. A. Jasenski to be decomposed in the gastro-intestinal tract, with absorption of the phenol and escape of the bismuth, in great part with the feces. It is also asserted by Jasenski that even the largest doses (seventy-five grains) of it produce no evidences of phenol poisoning, and the probabilities are that but a small portion of the compound suffers decomposition in the intestinal tract. It has been used in all forms of gastro-intestinal catarrhs, fermentative *dyspepsias*, and similar complaints, as an antiseptic; also to some extent locally in various mucous inflammations. *Dose*, eight to thirty grains (0.5–2 Gm.).

Bismuth-Cerium Salicylate is a reddish-white powder, insoluble in water and alcohol. This salt has been highly commended in *diarrhea*, *enteritis* and *dysentery* by Salaya. *Dose*, ten grains (0.65 Gm.). With ferric salts it gives a violet color and is decomposed by acids and acid salts.

Bismuth Chrysophanate. *Bismuthi Chrysophanas. Dermol. Bismuthum Chrysophanicum.* $Bi(C_{15}H_9O_4)2Bi_2O_3$.—This is a yellow, amorphous, insoluble powder, which has been used in the treatment of various diseases of the skin.

Bismuth Citrate. *Bismuthi Citras. U. S. VIII. Bismuthi Citricum, Citrate de Bismuth*, Fr. *Wismut-citrat, Citronensaures Wismutoxyd*, G. $BiC_6H_5O_7$.—This salt, which was formerly official for the purpose of manufacturing bismuth and ammonium citrate, is made by boiling together bismuth subnitrate and citric acid. For details of the process see *U. S. D.*, 19th edition, p. 237.

It is a white, amorphous, microcrystalline powder, odorless and tasteless. It is insoluble in water or alcohol but dissolves in ammonia water or in solutions of the alkali citrates. It is not used in medicine in its natural state.

A combination of bismuth citrate and ferric citrate (*Bismuthi et Ferri Citras*) corresponding to 21 per cent. bismuth and 9 per cent. of iron is marketed as *bismuth and iron citrate* (*soluble*). It occurs in yellowish-green scales and is readily soluble in water. It combines the therapeutic properties of its constituents and is intended for *dyspepsia* associated with *anemia*. *Dose*, five to ten grains (0.32–0.65 Gm.). The same manufacturers have also brought out a similar combination of lithium and bismuth citrate in soluble, colorless scales. It corresponds to 40 to 45 per cent. bismuth and 2.5 to 3 per cent. of lithium. It is incompatible with strongly alcoholic liquids, mineral acids and with some salts of heavy metals. It is recommended for *gouty dyspepsia* and *intestinal catarrh* in *doses* for adults of from five to fifteen grains (0.3–1.0 Gm.).

Bismuth Disalicylate.—Under the name of *Gastrosan* appears in commerce a white powder insoluble in cold water and alcohol which is asserted to be a disalicylate of bismuth. It is claimed for this preparation that it is superior in intestinal fermentation to other preparations of bismuth, because the second molecule of salicylic acid is liberated in the bowel and exercises an antiseptic influence. Witthauer has employed it with beneficial effects in *diarrhea* and in *gastric disturbances.* (*Ph. Centralh.*, 1909, p. 716.) It appeared in the form of lozenges each containing twelve grains (0.75 Gm.) of the salt.

Bismuth Ditannate. *Bismuth Tannate, Bismuth Bi-tannate.*—Under the trade name of *Tannismuth* this salt has been introduced into medicine. It is a light yellow powder, insoluble in water, and represents from 17 per cent. to 21 per cent. of bismuth, one atom of bismuth being combined with two molecules of tannic acid. It has been used in the treatment of *intestinal catarrh*, and by some is believed to be more astringent than the other insoluble salts of bismuth on the supposition that one of the tannic acid molecules will be split off in the intestinal tract. Sollmann (*J. P. Ex. T.*, 1921, xvii, 99) finds that tannismuth is more soluble in acid than in neutral or alkaline media; the portion dissolved by acids acts like free tannin. He believes that it exercises an astringent effect in the stomach and that in the intestines it acts like the insoluble salts of bismuth. The *dose* is five to thirty grains (0.3–2.0 Gm.).

Bismuth Dithiosalicylate. *Bismuthi Dithiosalicylas. Thioform. Deltaform.* $(S.C_6H_3(OH)COO.BiO_2 + Bi_2O_3 + 2H_2O$.—This is a yellowish-gray, odorless and tasteless powder, insoluble in water, alcohol, or ether, containing 72 per cent. bismuth oxide. It has been used externally as a dusting powder in *skin diseases* and in surgery, and probably acts precisely as does dermatol. It has been employed upon the eye to a considerable extent and is not irritant. Internally it has been given in *diarrhea as* an intestinal antiseptic in *doses* of five grains (0.32 Gm.) three or four times a day in capsules.

Bismuth Lactate. *Bismuthi Lactas.* $C_3H_4O_3BiHC_3H_4O_3$.—This salt is a white powder, slightly soluble in water and insoluble in alcohol. For process of manufacture see *U. S. D.*, 20th edition,

p. 1280. It may be used in *diarrhea* in *doses* of one to two grains (0.065–0.13 Gm.).

Bismuth Nucleinate.—*Bismuth paranucleinate* or *parabismuth* is a pale yellow, odorless, insoluble powder, containing about 50 per cent. of bismuth. It has been employed in the treatment of *enteritis* of both the acute and chronic types. *Dose,* fifteen to thirty grains (1–2 Gm.).

Bismuth Oleate. *Bismuthi Oleas.* $Bi(C_{17}H_{33}CO_2)_3$.—A compound resulting from the reaction between sodium oleate and bismuth trinitrate. It forms an insoluble powder or mass and is used as an emollient and astringent.

Bismuth Oxide. *Br.* 1898. *Bismuthi Oxidum. Bismuth Trioxide. Bismuthum Oxydatum, Oxydum Bismuthicum. Oxyde de Bismuth,* Fr. *Wismutoxyd,* G.—"Bismuth Oxide ($Bi_2O_3 = 464.00$), may be prepared by boiling bismuth oxynitrate with solution of sodium hydroxide." *Br.,* 1898. In this process the oxynitrate is decomposed by solution of sodium hydroxide, bismuth hydroxide being precipitated, while sodium nitrate remains in solution.

$$2BiNO_4.H_2O + 2NaOH = Bi_2 6OH \text{ (or } Bi_2O_3.3H_2O) + 2NaNO_3$$

At the temperature of 100° C. the bismuth hydroxide first produced is decomposed, water is liberated, and the anhydrous oxide is left. Bismuth oxide is a powder of a dull lemon-yellow color, insoluble in water, but soluble without effervescence in nitric acid, mixed with half its volume of water. The British Pharmacopœia, 1898, describes it as "a slightly brownish-yellow powder. It should answer to the general characters and tests enumerated under 'Bismuth Oxycarbonate.' Each gramme should yield 1.1 grammes of bismuth sulphide. Heated to incipient redness it is scarcely diminished in weight (absence of bismuth oxycarbonate, bismuth oxynitrate, and moisture)." *Br.,* 1898. It resembles bismuth subnitrate in its medicinal properties, and may be administered in *doses* of from ten to thirty grains (0.65–2.0 Gm.).

Bismuth Oxychloride. *Bismuthi Oxychloridum seu Subchloridum. Bismuth Subchloride. Bismuthyl Chloride. Flake White. Oxychlorure de bismuth,* Fr. *Wismutoxychlorid,* G. BiOCl.—Made by slowly pouring a solution of bismuth trinitrate, in diluted nitric acid, into a solution of sodium chloride, collecting the white precipitate, washing and drying. It is sometimes known as *pearl white,* and in France as *blanc de fard,* or *blanc d'Espagne.* Bismuth oxychloride is insoluble in water, soluble in acids, and is used for the same purposes as bismuth subnitrate and also for cosmetic purposes.

Bismuth Oxyiodide. *Bismuthi Oxyiodidum.* BiOI. *Bismuth Subiodide. Bismuthyl Iodide.*—For F. X. Moerk's process for the preparation of this salt, see *U. S. D.,* 19th ed., p. 1416. The oxyiodide has a light yellowish-red color, and contains no water or crystallization. (*A. J. P.,* 1887, 273.) In 1877 the bismuth oxyiodide was recommended as a local antiseptic and substitute for iodoform, by A. Sidney Reynolds. It has been used to a considerable extent with success in the Philadelphia Hospital, but its high price interferes with its general adoption. It has also been given internally in *gastric ulcer* and other gastric affections for which bismuth is usually employed. The *dose* is from five to ten grains (0.32–0.65 Gm.). Under the name of *bismuth formic iodide* a mixture of formaldehyde-gelatin, thymol iodide, and bismuth sub-iodide is marketed as an antiseptic dusting powder to ulcers and *sores* that require stimulant action.

Bismuth Oxyiodogallate. *Bismuth Iodsubgallate. Airol. Airoform. Airogen.* $C_6H_2(OH)_3COO(BiOHI)$.—This is a basic combination of bismuth, oxygen, iodine, and gallic acid, containing in 100 parts 44.6 parts of bismuth trioxide and 24.3 parts of iodine. It is prepared by heating molecular quantities of bismuth subgallate and hydriodic acid or bismuth oxyiodide and gallic acid in the presence of water until a grayish-green product results which is collected, washed and dried. It is a grayish-green odorless and tasteless powder insoluble in alcohol, ether, chloroform and olive oil, slightly soluble in glycerin. It is decomposed upon contact with water or aqueous solutions, slowly in the cold, more rapidly by heat. Airol is incompatible with water, diluted acids, dilute alkalies, etc., and it should be kept dry, as moist air causes liberation of iodine.

When airol is brought in contact with surgical secretions it becomes red from the liberation of iodine. According to the researches of Carl S. Haegler (Bruns, *B. k. Ch.,* xv, 1896), it is about as feeble an antiseptic as is iodoform, but as in the case of iodoform the substances liberated by its decomposition in wounds are actively germicidal. Von Herrenschwand (*Archiv. fur Ophthalm.,* 1913, lxxxii) finds, however, that one part of airol in a thousand is capable of killing gonococci and that one in ten thousand completely inhibits their growth. It has been largely used as a local remedy in all cases for which iodoform has been employed, having the superiority over that substance of being nearly free from odor. It does not irritate, but rapidly desiccates ulcerated surfaces. In the only case of poisoning by it which we have found recorded, symptoms of bismuth poisoning followed the injection into the cavity of an abscess of nine and a half fluidrachms (35 cc.) of its 10 per cent. solution in glycerin (Nemmer).

Injected into the peritoneal cavities of the lower animals in the dose of from one to two grammes per kilo, airol causes colonic convulsions, with coma, nephritis, and fatty degeneration of the liver.

It may be used as a powder or as a 10 to 20 per cent. salve, which should be prepared with lard or vaseline free from water, since with water, airol undergoes rapid decomposition. Airol is used as an antiseptic dusting powder in the treatment of *wounds.* It has been found of service as a local remedy in various *catarrhs,* as *vaginitis* or *rhinitis.* Bernheimer has used airol successfully in the treatment of gonorrheal *opthalmia.* The eye is first carefully cleansed and the everted lids are then dusted with the finely powdered drug. This procedure is to be repeated several times a day. A 10 per cent. glycerin emulsion has been recommended as an injection into *tubercular abscess* cavities.

Brun's Paste, which has been much used in various skin diseases and ulcerations, is made according to the following formula: Airol, *one part;* Mucilage, *two parts;* Glycerin, *two parts;* Argilla Alba (Kaolin), *sufficient to make a soft paste.* If the paste becomes too dry, use glycerin; if it be too soft, kaolin may be added. No metal instruments should be employed in preparing the paste, since many metals liberate iodine from airol. For the same reason, no water, only glycerin, should be used in the preparation. The paste is preserved in well-stoppered glass or porcelain jars, which are to be kept closed.

Bismuth Oxyiodo-methyl-gallol. *Bismuthi Oxyiodo-methylgallolum. Iodo-gallicin.* $C_6H_2COOCH_3(OH)_2O.BiOH.I$.—Made by acting upon gallicin (methyl gallate) with bismuth oxyiodide. It is in the form of a light, amorphous, dark gray powder, insoluble in ordinary solvents and containing 23.6 per cent. of iodine and 38.4 per cent. of bismuth.

It is used as a siccative and antiseptic powder to replace iodoform.

Bismuth Oxyiodo-pyrogallate. *Bismuthi Oxyiodo-pyrogallas. Pyroform. Gammaform.* $C_6H_2(OH)_2.O.Bi(OH)I$.—Made by digesting bismuth oxyiodide with pyrogallic acid or by precipitating a solution of potassium iodide and pyrogallic acid with bismuth nitrate in acetic acid. A fine, amorphous, yellowish-red powder, permanent in light and air. It is recommended as a surgical antiseptic powder.

Bismuth Oxyiodo-tannate. *Bismuthi Oxyiodotannas. Ibit.*—Bismuth oxyiodo-tannate is a greenish-gray, odorless, tasteless powder, becoming brownish on exposure, insoluble in water, and has been suggested as a surgical substitute for iodoform.

Bismuth Phenolate. *Bismuthi Phenolas. Bismuth Carbolate. Phenol-wismut,* G. $C_6H_5O.Bi(OH)_2$.—Made by a reaction between solutions of bismuth trinitrate and sodium phenolate. A gray, insoluble, inodorous powder, used as an intestinal antiseptic, in *doses* of from eight to fifteen grains (0.5–1.0 Gm.), also as an antiseptic dusting-powder.

Bismuth Phosphate, Soluble. $BiPO_4$. *Bismuthi Phosphas Solubilis. Bisol.*—This is prepared by the melting together of bismuth, sodium hydroxide, and phosphoric acid. It is a white powder easily soluble in water, precipitated by alkalies, acids, or heat, and undergoing spontaneous decomposition when in concentrated solution. It contains 20 per cent. of bismuth, and has been used as an intestinal antiseptic in *choleraic* and other acute *diarrheas* in the *dose* of from three to eight grains (0.2–0.5 Gm.) three times a day.

Bismuth Pyrogallate. *Bismuthi Pyrogallas. Helcosol. Helsosal.* $C_6H_3(OH)_2OBiOH$.—It is a yellowish-green amorphous powder, insoluble in water and alcohol, soluble in acid and alkaline solutions and in the gastro-intestinal juices. According to von Heyden, it represents about 60 per cent. of bismuth oxide. It is said to be non-poisonous, and to be a valuable intestinal antiseptic; if, however, pyrogallic acid should be liberated in the alimentary canal, it might produce disagreeable effects, and the remedy seems to us dangerous. It is asserted that acids liberate pyrogallic acid from this combination, thus contradicting the previous statement. It is incompatible with strong alkalies and alkaline sulphur compounds.

Bismuth Subbenzoate, or *basic bismuth benzoate,* $Bi(C_7H_5O_2)_3Bi(OH)_3$, is a white powder containing 60 to 70 per cent. of Bi_2O_2. It is insoluble in water and used externally as a dry dressing in *syphilitic ulcers.*

Bismuth Tribromphenate. *Bismuthi Tribromphenas, N. N. R.,* 1924. *Tribromphenol-bismuth. Xeroform. Bromphenolis.* $Bi_2O_3(C_6H_2Br_3OH)$.—This is a yellowish-green, insoluble, almost odorless and tasteless powder, which, according to its manufacturer, is a chemical combination of bismuth and tribromphenol, containing about 50 per cent. of bismuth oxide.

It is practically insoluble in water or the ordinary solvents but dissolves readily in diluted hydrochloric acids.

Xeroform has been widely used as a substitute for iodoform in various surgical procedures. The advantages claimed for it are that it is not only practically odorless, but is also non-toxic, and that it exercises a more powerful antiseptic effect. It appears also to possess to a considerable degree the analgesic action, as well as the desiccating and antiseptic effect of iodoform on *wounds.* It has also been employed as a substitute for the salts of bismuth in the treatment of *enteritis, gastric ulcer* and similar conditions. For the latter purpose it is administered in *doses* of from 8 to 15 grains (0.5–1.0 Gm.).

Bismuth Valerate. *Bismuthi Valeras. Valérianate de Bismuth,* Fr. *Wismutvalerianat,* G. $Bi(C_5H_9O_2)_3 2Bi(OH)_3$.—This salt is formed by double decomposition between solutions of bismuth trinitrate and sodium valerate. Bismuth valerate precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in *neuralgia,* and in *gastrodynia.* The *dose* is from half a grain to two grains (0.03–0.13 Gm.), repeated several times a day, and given in the form of pill.

Bistort. *Snakeweed. Bistorte, Couleuvrine,* Fr. *Weissenknöterich, Natterwurz,* G.—This is the rhizome of *Polygonum Bistorta,* L. (Fam. *Polygonaceæ*), a perennial herbaceous plant, growing in Europe and the north of Asia. The rhizome is cylindrical, somewhat flattened, about 1 to 2 cm. in thickness, marked with annular or transverse wrinkles, furnished with numerous rootlets, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. Externally it is dark purplish or blackish-brown. The fracture is nearly smooth, reddish or purple, the taste being astringent. It contains much tannin, some gallic acid and gum, and a large proportion of starch. H. K. Bowman found 21 per cent. of tannin in bistort root. (*A. J. P.,* 1869, 193.) Its medicinal properties are like those of kino, but it is less efficient. It may be employed in powder, decoction, or extract. The *dose* of the powder is twenty to thirty grains (1.3–2.0 Gm.).

Besides the bistort, some other plants belonging to the genus *Polygonum* have been used as medicines. Steenhauer (*Pharm. Weekblad.,* 1919, lvi, 1084) has made careful botanical and chemical examination of several species of *Polygonum,* the most interesting result of which is the finding in a number of them of small amounts of emodin ranging from 0.02 to 0.08 per cent.

Among the species which have been used as medicines are *P. aviculare,* L., or *knot weed,* a mild astringent, formerly employed as a vulnerary and styptic; *P. Persicaria,* L., or *lady's thumb,* of a feebly astringent saline taste, and at one time considered antiseptic; and *P. hydropiper,* L., common *smartweed,* or *water-pepper,* the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic, and have been used with asserted success in *amenorrhea* and other *uterine disorders.* Its irritant and also medicinal properties are due to an acid, *polygonic acid,* discovered by C. J. Rademaker. *Polygonum Hydropiper* has been used by Krawkoff (*Russki Vratch,* 1912) in the treatment of *internal hemorrhages*, especially of the uterus. He administered from thirty to forty drops of a fluidextract of the leaves. (*A. J. P.*, xliii, 490.) The *water-pepper* or *smartweed* of this country—*P. acre* H. B. K.—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic *ulcers*, and internally in *gravel*. B. Woodward found that the dried plant contains 18 per cent. of tannin, and used a saturated tincture with great advantage in *diarrhea* and *dysentery*, in *doses* of from twenty to sixty minims (1.3–3.75 cc.). Aughey finds that *P. amphibium*, L., is readily cultivated, with a yield of from three to six tons to the acre, that the roots contain 21.75 per cent., the stems 17.1 per cent. of tannic acid, and urges the growth of it for tanning purposes. (*N. R.*, 1876, 75.)

Fagopyrum esculentum Moench (*Polygonum Fagopyrum* L.) is common *buckwheat*. The leaves of this plant have been found by Ed. Schunck to contain a crystallizable coloring principle, identical with the *rutin* or *rutic acid* previously discovered by Weiss in the leaves of the common rue, and probably, with the *ilexanthin* of Moldenhaus, existing in the leaves of *Ilex Aquifolium* L., or the common holly. Buckwheat leaves yielded to Schunck somewhat more than one part of rutin in a thousand.

From *P. cuspidatum* L. has been separated a glucoside, *polygonin*, and also *emodin*. (*P. J.*, Feb., 1896.) The bark of the rhizome has been recommended by Goris and Crète (*Bull. Sci. Pharmacol.*, 1907) as a laxative. The leaves of the *P. dumetorium* are, according to Tunmann (*Ph. Centralh.*, 1906), also practically useful as a laxative.

Various species of the genus *Polygonum* have been used for the production of dye-stuffs; thus indigo is obtained largely in China, Japan, and in some parts of Russia, from the leaves of *P. tinctorium* Ait., and is said also to be yielded by those of *P. aviculare* and *P. barbatum*, L.; while in India, China, and Japan the roots of the *P. cuspidatum* are employed for making a yellow dye. (*J. Chem. S.*, Dec., 1895.)

Bituminol. *Ammonium Sulpho-Bituminolate.*—This substance, manufactured by a German firm, is used as a substitute for ichthyol.

Blennostasine. *Cinchonidine dihydrobromide.*—This forms yellowish, deliquescent crystals and is freely soluble in water. W. F. Campbell (*N. Y. M. J.*, lxiv, 1896) asserted that it is a powerful sedative to the brain and spinal cord, and that in *doses* of from one to four grains (0.065–0.26 Gm.) every hour it is a valuable remedy in nasal and laryngeal hyperesthesia. It has been especially recommended to check excessive secretions in *acute coryza*.

Blood.—As long ago as 1852, Samuel Jackson, of Philadelphia, employed as a tonic the blood of bullocks carefully dried *in vacuo*, giving from five to ten grains (0.32–0.65 Gm.) of it as a *dose*. At one time it was used considerably in Europe, and even drinking fresh bullock's blood was at one time in fashion. Under the name of *Sanguis Bovinus Exsiccatus*, F. E. Stewart introduced defibrinated dried bullock's blood, claiming for it that, by the simple addition of water, bullock's blood can be reproduced minus a small quantity of fibrin. There is no reason for believing that dried blood is more valuable than the more usual ferruginous tonics, if indeed it be of equal value.

The hypodermic injection of blood serum increases the coagulability of the blood and has therefore been used in the treatment of internal *hemorrhages*. There are a number of preparations of blood intended for this use upon the market. *Coagulose* is a desiccated, sterilized horse serum. It is marketed in sealed bulbs each containing 1 grain (0.065 Gm.) of the powder, which is equivalent to 10 cc. of blood serum. This powder is administered by dissolving in sterilized water and injecting the resulting solution hypodermically. *Hemostatic Serum* (*Hemoplastin*) is another preparation of blood intended for use as a coagulant. It occurs as a light, amber-colored liquid. It may be given hypodermically in doses of 1 to 2 cc. (15 to 30 minims). The injection of whole serum is open to the disadvantage that along with the desired coagulating elements there are injected useless and even dangerous protein substances, notably those which give rise to anaphylaxis. In order to obviate this objection there has been placed upon the market under the name of *Coagulen* (introduced by Kocher and Fonio, *K. S. A.*, 1913) an extract which is said to be made from the blood platelets and to contain the thromboplastic substances of the blood mixed with lactose. It occurs as a yellowish, granular powder, freely soluble in water. It is administered generally in the form of a 5 per cent. solution made in physiological salt solution and sterilized by boiling for 2 or 3 minutes. For further information on the subject see under *Thromboplastin*. Curtis (*J. A. M. A.*, 1915, lxiv, p. 332) has found the hypodermic injection of whole human blood to be equally efficacious. He administered subcutaneously from ten to twenty cc.

Blumea. *Blumea lacera* DC. (Fam. *Compositæ.*)—From this plant which is used in India as an insect powder, Dymock has obtained a light yellow volatile oil. It has a sp. gr. of 0.9144 at 26.7° C., and an extraordinary rotating power, 1 mm. turning the ray 66° to the left.

A camphor has been obtained from *Blumea balsamifera* DC. and *B. densiflora* DC., two shrubs indigenous to the Himalayas, by subjecting the entire plants to distillation. That obtained from the last named is known as Ngai camphor (see *Camphora*). *Blumea densiflora* DC., a tall weed, abundant on cut-over forest lands in Savoy, Burma, is claimed to yield a camphor identical with Chinese camphor. (*C. D.*, 1920, p. 425).

Bocconia.—It is probable that various species of this papaveraceous genus have active medicinal properties. *B. arborea* Watson, of Mexico, has been found by Elliott to contain two alkaloids, one of which is probably sanguinarine; and the leaves of other species are used in South America as an abortifacient and purgative. (See Rusby, *Bull. Pharm.*, 1891.) Murrill and Schlotterbeck (*Proc. A. Ph. A.*, 1900, p. 128) examined all parts of *Bocconia cordata*, and isolated protopine, homochelidonine, chelerythrine and sanguinarine.

Bole Armenian. *Bolus Armeniæ. Bolus Rubra. Argilla Ferruginea.*—The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in color or in place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft, and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of a hydrated aluminum silicate with ferric hydrate. The boles were formerly employed as absorbents and astringents in *acidity of the stomach* and in *relaxed bowels*. Bole Armenian is used chiefly as a coloring ingredient in toothpowders.

Bonduc Seeds.—These are seeds derived from *Cæsalpinia Bonducella* Fleming (Fam. *Leguminosæ*), a tree indigenous to India, which are used in India as febrifuge, tonic, and antiperiodic. Heckel and Schlagdenhauffen have discovered in them a bitter principle (*C. R. A. S.*, ciii, 89), probably identical with that previously isolated by Flückiger. (*Pharmacographia*, 2d ed., 212.)

Bone. *Os*, Lat., Fr. *Knochen*, G. *Ossa*, It. *Huesos*, Sp.—Under the name of *Os Ustum*, or *Bone ash*, the Br. Pharmacopœia formerly recognized "the residue of Bones, which have been burned to a white ash in contact with air. Bone ash consists principally of phosphate of calcium, mixed with about 10 per cent. of carbonate of calcium and a little calcium fluoride, silica, and magnesium phosphate." *Br.*, 1867. When bones are subjected to destructive distillation, in closed vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle and are converted into a black substance, containing the inorganic compounds (principally calcium phosphate) of the bone, and constituting the species of animal charcoal called *bone black*. (See *Carbo Animalis.*) The portions which distil over consist of the usual ammoniacal products derived from animal matter, but are especially rich in nitrogenous bases of the pyridine and quinoline series. (See *Ammonii Chloridum.*)

When calcined in open vessels, bones are converted into a white friable substance consisting of the incombustible part, and commonly called *bone earth*, or *bone ash;* and a similar residue is obtained by calcining horns, and is termed *Cornu Ustum*. When bones are treated with boiling water, a small portion of the gelatinous matter is dissolved; but when acted on by water in a Papin's digester, the whole of it is taken up and the inorganic compounds, deprived of their cement, crumble into powder, and become diffused through the solution. When bone is acted on by diluted hydrochloric acid, the inorganic compounds are dissolved, and the bone softens without losing its shape and becomes semitransparent and flexible. The portion remaining unattacked by the acid is the nitrogenous tissue (known as *ossein*), which may be converted into gelatin by boiling with water. The feet of cattle, deprived of the hoofs, boiled with water, furnish a fatty oil, called *neat's-foot oil.*

The bones of different animals, and of the same animal at different ages, vary somewhat in composition. Dry ox bones consist of bone gelatin (cartilage of bone) 33.3, calcium phosphate with a little calcium fluoride 57.35, calcium carbonate 3.85, magnesium phosphate 2.05, and sodium hydroxide with a very little sodium chloride 3.45. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to W. Heintz, however, bones exhausted by water, so as to remove the coloring matter of blood, do not contain a trace of iron. Marchand found 1 per cent. of calcium fluoride in human bone. *Calcium bone phosphate* consists of the tribasic phosphate, $Ca_3(PO_4)_2$.

Borago. *Borago officinalis*, L. *Borage. Bourrache*, Fr. *Borasch, Boretsch*, G. (Fam. *Boraginaceæ.*)—A coarse, hairy annual, attaining a height of 1½ to 2 ft., with ovate to oblong leaves and racemes of blue flowers. It is indigenous to Europe and northern Africa. It abounds in mucilage, and the stems and leaves contain potassium nitrate with other salts. To these constituents the plant owes its feeble medicinal properties. An infusion of the leaves and flowers is employed as a demulcent, refrigerant, and gently diaphoretic drink. The expressed juice of the stems and leaves is also given in the *dose* of from two to four fluidounces (60–120 cc.).

Bordisalicylic Acid.—This preparation represents ortho-boric acid in which two hydroxyl groups have been replaced by salicyl radicals, having the formula $OHB(OC_6H_4.COOH)_2$.

It is readily soluble in water, alcohol or glycerin, the solutions being very bitter. It is asserted to be actively germicidal and non-toxic.

Bornyval.—This isovaleric ester of borneol, $CH_3CH(CH_3).CH_2CO.O(C_{10}H_{17})$, $C_{10}H_{17}O.C_5H_9O$, is a limpid fluid with an aromatic odor, suggesting valerian; soluble in alcohol and ether, insoluble in water; boiling under ordinary pressure, at 255° to 260° C., sp. gr. at 20° C. 0.951. Polariscopic rotation: $[a]_D$ 20° = 27° 40′. Bornyval has been highly lauded by a number of physicians in the same class of cases in which valerian is commonly employed, such as *nervous headache, neurasthenia, dysmenorrhea*, and the like. It has also been recommended in the treatment of various forms of *sexual disturbances*, and even in *epilepsy*. The *dose* is four to eight minims (0.25–0.5 cc.) several times a day.

Under the name of *Neo bornyval*, the iso-valerylglycolic ester has been introduced. This is supposed to have the advantage over the older bornyval in that it is less easily affected by the gastric juices and therefore less liable to give rise to disturbances of the stomach. It is used for the same purposes as bornyval and appears in commerce in the form of pearls, each of which contains 0.25 Gm. (3½ gr.). Of these one to three may be given at a *dose*. (See also *Brovalol* and *Gynoval.*)

Borogen.—This is the ethyl ester of boric acid, $B(O.C_2H_5)_3$. It is a liquid, boiling at 120° C., which is decomposed by water into boric acid and alcohol. It is inflammable, burning with a green flame. This substance has been suggested as a local remedy in diseases of the nasal and respiratory mucous membrane, under the belief that it is decomposed into its constituents in the throat and lungs. Borogen is used by inhalation.

Boroglyceride. *Boroglycerinum. Glyceryl borate.*—This substance has been largely employed as a convenient form of obtaining boric acid in a soluble condition. It is made by heating boric acid and glycerin together so as to effect a combination without discoloring the product by overheating. (See *Glyceritum Boroglycerini*, Part I.) James Kennedy (*Nat. Drug.*, 1887, 46) maintained that it is a chemical compound, and not a mere mechanical mixture, as has been supposed;

he gave it the formula $C_3H_5BO_3$, and expressed the reaction in its formation thus:

$$C_3H_5(OH)_3 + H_3BO_3 = C_3H_5BO_3 + 3H_2O$$

The metallic boroglycerides, such as sodium and calcium boroglyceride, are not explained, however, in this case. Aqueous solutions of boroglyceride were formerly used for preserving milk, meat, fruit juices, etc., but are now prohibited by law. Boroglyceride has been largely sold in England under the name of *glacialin*.

Bowdichia. *Bowdichia virgiliodes* H. B. K. (Fam. *Leguminosæ.*)—Under the name of *Alcornoco bark*, or *Sucupira*, the hard, yellow, very bitter bark yielded by this tree is employed in Venezuela and Brazil in *fevers* and *rheumatism*. Petit has found it in a mydriatic alkaloid. (*P. J.*, June, 1885.)

Bragantia. *Bragantia Wallichii* R. Br. (Fam. *Aristolochiaceæ.*)—The roots of this shrub of India contain an alkaloid allied to aristolochine, a soft resin, a resinous acid, and a substance related to dulcite. (*P. J.*, 1894, 231.)

Brassica.—In China the oil of *Brassica sinensis*, or *petsai*, is used for lighting, and is said also to be purgative, and useful in *skin diseases*, while the Japanese employ the yellow oil of *B. Campestris*, L., under the name of *aburana*, for culinary and lighting purposes. (*A. J. P.*, June, 1885.)

Brazil Nuts. *Cream Nuts. Butter Nuts* (not to be confused with the nuts similarly named and obtained from *Juglans cinera* L.). *Para Nuts. Chataigne du Brésil*, Fr. *Paranuss*, G.—These edible nuts imported from Brazil, are the product of *Bertholletia excelsa* Humb. et Bpl. and *B. nobilis* Miers, a large and beautiful tree of the Fam. *Myrtaceæ*, growing over extensive regions in South America. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. Cornwinder has found in the kernel of the nut 65.60 per cent. of oil, and 15.31 per cent. of nitrogenous matter. (*P. J.*, Aug., 1873.) Hugo Kühl obtained from the seeds an average fat-content of 62.73 per cent. with 2.59 per cent. of nitrogen, corresponding to 16.20 per cent. of proteins. (*Ph. Ztg.*, 1909, No. 6, 58.)

Brazil Wood.—This is a red-dye wood claimed by Taubert to be derived from *Cæsalpinia Echinata* Lam., a tree indigenous to South America and known to the Brazilians as *Ibira pitanga* or *ymirá pirango*. The part collected represents the heartwood which is gathered in Brazil. It occurs in heavy pieces of variable length and of arm thickness, externally reddish-brown to reddish-black, internally yellowish-red and fine grained. A smaller commercial variety of red-dye wood which has been sold for Brazil wood comes from the West Indies and is yielded chiefly by *C. cristata* L. and *C. bijuga* Sw. The heartwood of *C. Sappan* L., commonly known as *Indian Redwood, Sappan* or *False Sandalwood* is also to be found in commerce as a colorwood. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its coloring matter to water. It was formerly used in medicine, but has been abandoned as inert. In pharmacy, it serves to color tinctures, etc., but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are due to a crystallizable coloring principle, named *brazilin* or *brasilin*, $C_{16}H_{14}O_5$. This, as usually obtained, is of a sulphur-yellow color, which it preserves in the dark, but in the sunlight, to which it is remarkably sensitive, changes to a reddish hue after a few minutes' exposure, and also more slowly in diffused daylight. The principle should, therefore, be kept in perfectly opaque vessels. It is now stated that when absolutely pure it is colorless, and becomes red on exposure to the air. The change is due to the formation of *brasilein*, $C_{16}H_{12}O_5$, which can be prepared from the brasilin by a variety of methods, such as oxidation by nitrous acid, by alcoholic iodine solution, etc. Brasilin is sparingly soluble in water, yielding a sweet and almost colorless solution which is not changed by acids, but is deeply reddened by alkalies. In alcohol and ether it is somewhat more soluble than in water, giving a light yellow solution. Brasilin and hematoxylin (from logwood) are now recognized as related, each being derived from the pyrone nucleus $C_5H_4O_2$, from which the two groups, the xanthone group and the flavone group, are also taken. The coloring principles of most dye-woods are now referred to this source. (Kupe, *Die Chemie der natürlichen Farbstoffe*, Braunschweig, 1900.)

Brea Gum.—This substance, which has been proposed as a substitute for gum arabic, is believed to be derived from *Cæsalpinia præcox* Ruiz et Pavon, a Brazilian tree. It occurs in stalactitic pieces or oval reddish-yellow tears, isolated or agglomerated. It forms with water a viscous, pale reddish-yellow mucilage, of acid reaction, which may be partially decolorized by heating with a few drops of hydrochloric acid. It is said to contain 77 per cent. of arabin.

Algarobilla, the pod of *Cæsalpinia brevifolia*, (Clos.) Benth. which contains over 60 per cent. of tannin and a quantity of *ellagic acid*, is obtained from Chili. (*J. Chem. S.*, 1891, 918.)

Bromal. *Tribromacetaldehyde.* C_2HBr_3O.—This substance is the bromine analogue of chloral which it resembles in its chemical properties, like it existing as an oily, colorless liquid, or, when united with water or alcohol, as a crystalline hydrate or alcoholate. It is prepared by the action of bromine on alcohol; when water is added *bromal hydrate*, $C_2HBr_3O.H_2O$, is formed in rhombic scales fusing at 53.5° C. This was at once suggested as a nerve sedative but did not prove clinically useful. For further information see *U. S. D.*, 20th edition, p. 1286.

Bromalbacid. *Albumen Bromate.*—This substance, whose therapeutic action is said to be identical with that of the bromides, is a *bromated egg albumen*. It is soluble in water and is administered in seven to ten grain (0.5 to 0.6 Gm.) *doses*.

Brometone. *Tribrom Tertiary-Butyl Alcohol. Acetone-Bromoform. N. N. R.* 1924. $CBr_3C(OH)(CH_3).CH_3$.—It is produced by the action of acetone on bromoform in a caustic alkali solution. It occurs in fine, white, prismatic crystals possessing a camphoraceous odor and taste. It is soluble in water and in almost all organic solvents. Brometone is said to have the sedative action of the bromides without the disadvantage of producing bromism. *Dose*, five grains (0.32 Gm.)

Bromine Chloride. *Bromi Chloridum.* BrCl.—This chloride is prepared by passing chlorine gas through bromine, and condensing the vapors which form, by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a powerful odor and cause a flow of tears. Its taste is hot and unpleasant. Lebeau doubts the existence of bromine chloride and states that it is a mixture of bromine and chlorine in which the chlorine is simply in solution in bromine. (*Chem. News*, 1906, 241.) Bromine chloride was used by Landolfi, of Naples, internally, in the treatment of *cancer* and as an ingredient in his caustic.

Bromipin. *Brominol. Brominized Sesame Oil. N. N. R.*, 1924.—This preparation, which is the analogue of iodipin, is a bromine addition product of sesame oil containing about ten per cent. of bromine in organic combination. It occurs as a yellow oily liquid with a purely oleaginous taste.

When bromipin is taken by the mouth it passes through the stomach unchanged; but in the intestines a portion of it is broken up by the fat splitting ferments, the bromin, which is liberated, then being absorbed as an inorganic bromide. Apparently, however, a portion of the bromipin is absorbed unchanged and deposited in the fat and lipoid tissues of the body, from which it is slowly given up to the system. Its action, therefore, is slower and more persistent than the ordinary bromides. It may be used as a substitute for the inorganic bromides whenever a prolonged action is desired, as in the treatment of *epilepsy, neurasthenia,* and the like. The dose is ordinarily from one to two fluidrachms (4–8 cc.) which, however, is often exceeded in cases of epilepsy.

Bromochinal. *Bromoquinal. Acid Quinine dibromsalicylate.* $C_{20}H_{24}O_2N_{2}.2(C_6H_2Br_2.OH.COOH)_2$.—Bromochinal occurs in yellow crystals, sparingly soluble in water, alcohol, or ether. According to Von Noorden, in *doses* of nine to twelve grains (0.6–0.78 Gm.) given twice a day, it acts as a feeble antipyretic and is also soporific. (*Ther. Geg.*, v.)

Bromocoll. *Dibromtannin-gelatin.*—This is a yellow, tasteless, odorless powder, composed of 20 per cent. of bromine, 10 per cent. of water, 30 per cent. of gelatin, and 40 per cent. of tannic acid. According to the experiments of Brat (*Th. M.*, 1901, xv, 4), bromocoll is very resistant to gastric juice, but is readily dissolved with decomposition in the intestinal juices. It is claimed that it acts precisely like the bromides, but produces the disagreeable symptoms of bromism only in a very mild degree. Friedländer (*Th. M.*, 1901) determined by experimentation that it depresses the irritability of the psychomotor centers. Meier (*Med. Klin.*, 1906) has found that the subcutaneous injection of bromocoll is useful, at least in the lower animals in strychnine poisoning and in *tetanus.* The *dose* is thirty to seventy-five grains (2–5 Gm.) a day.

Bromoform. *Bromoformum. U. S. IX. Tribrommethane, Formyl Tribromide; Bromo-formium* P. G.; *Bromoform, Tribrommethan,* G.; *Bromoformo,* Sp.—"A liquid consisting of about 96 per cent., by weight, of $CHBr_3$ (252.77) and about 4 per cent. of dehydrated alcohol. Preserve it in glass-stoppered bottles, in a cool place, protected from light." *U. S. IX.*

This compound, the analogue of chloroform, is prepared by methods similar to those used for the manufacture of chloroform.

Bromoform is officially described as "a heavy, transparent, colorless, mobile liquid, with an ethereal odor, and a penetrating, sweet taste, resembling that of chloroform. Bromoform is slightly soluble in water; miscible with alcohol, chloroform, ether, benzene, petroleum benzin or fixed or volatile oils. Specific gravity: 2.595 to 2.620 at 25° C. Bromoform is slightly volatile at ordinary temperatures. Bromoform is not inflammable, but when vaporized by the application of heat, its vapors may be ignited. Evaporate 10 mils of Bromoform from a porcelain dish on a water bath; not more than 0.006 Gm. of residue remains after drying at 100° C. Shake 10 mils of Bromoform with 10 mils of distilled water, and allow the liquids to separate completely. The water removed from the layer of Bromoform is neutral to litmus (*free acid*); 5-mil portions, tested separately, show not more than a slight opalescence on the addition of a few drops of silver nitrate T.S. (*bromides or brominated compounds*), and no blue color on the addition of a few drops each of potassium iodide T.S. and of starch T.S. (*free bromine*). Agitate 10 mils of Bromoform with 10 mils of distilled water, and allow the liquids to separate completely. Remove the aqueous layer from the Bromoform, treat it with an excess of ammonia water, and then with a solution of iodine and ammonium iodide, until the black precipitate of nitrogen iodide, which sometimes forms, slowly disappears; it does not become milky in appearance, due to the separation of iodoform, recognizable by its odor (*acetone*)." *U. S. IX.*

At one time bromoform was suggested as a general anesthetic. Experience has shown, however, that although bromoform produces a rapid narcosis when inhaled, its employment is attended with excessive danger. When taken internally by the mouth it is capable of acting like the older bromides, but it has no advantages and is a much more dangerous remedy. In the recorded cases of poisoning by it the symptoms have been pallor, titubation, dilatation of the pupils, coma, heart failure and collapse.

In the latter part of the last century bromoform was brought forward as a remedy for *whooping-cough.* It enjoyed for some time a considerable popularity but has been largely abandoned because of its dangerous effects. Three drops are said to have produced very serious symptoms in a child of four years, and two drops in one of fifteen months. For cases of poisoning, see *Cb. I. M.*, No. 50, 1902; *B. M. J.*, vol. i, 1900; *T. G.;* 1903; *Ap. Ztg.*, July, 1898, March 24, 1900. A saturated aqueous solution of bromoform (containing about 0.3 per cent.) has been recommended by Desesquell (*B. M.*, 1907) for the relief of *sea-sickness,* in tablespoonful doses.

Dose, one to five minims (0.06 to 0.3 cc.), best administered in capsules, dropped on sugar, or mixed with an equal quantity of olive oil and emulsified.

Bromolein is a compound which contains bromine in combination with the unsaturated fatty oleins of the almond oil for their saturation. This substance, introduced by Coronedi and Marchetti (*Settimana med.*, 1899, liii), is a yellow, clear, oily liquid, containing 20 per cent. of bromine. The *dose* of bromolein is from one-half to one fluidrachm (1.9–3.9 cc.).

Bromophenol.—*Phenol Monobromate. Orthomonobromphenol,* $C_6H_4Br.OH$, is obtained by the combination of bromine and phenol at a temperature of 150°–180° C. It is a dark yellow, oily, strong smelling fluid, soluble in alcohol and ether, slightly in water. It is used as a two per cent. ointment in the treatment of *erysipelas,* also to disinfect the sputum. See also *Tribromphenol.*)

Bromophor.—This preparation, which is stated to be the *dibrom-ricinoleate* is recommended as an external application in *pruritus* and *erysipelas*. According to Linke, however (*Ther. Neuheiten*, March, 1910), its use in *erysipelas* is not to be recommended because of its intense irritation of the skin.

Bromotan.—*Bromotannin-methylene Urea* is a light brown, odorless and tasteless powder, insoluble in water. It has been employed by Rockstroth (*Th. M.*, 1906) as a dusting powder in the treatment of moist *eczema*.

Bromural. *N. N. R.* 1924. *Alpha-monobromisovaleryl Urea.* $(CH_3)_2CH.CH.Br.CO.NH.CO.NH_2$.—This occurs as white, almost tasteless, needle-like crystals, soluble in hot water, ether, and alcohol, but only sparingly in cold water. Its melting point is 147°–149° C. Bromural has been widely employed as a general nerve sedative and as a mild somnifacient. Eeckhout (*A. E. P. P.*, lvii, p. 338) administered to a rabbit 0.1 Gm. daily for two weeks with no apparent disturbance of the health. Sollmann and Hatcher (*J. A. M. A.*, 1908, li, p. 487), however, have found that in cats the relation of the sleep-producing to the fatal dose of bromural was practically the same as that of chloral, and that the effects of bromural come on even more quickly than those of chloral hydrate and last for a comparatively short time. According to Eeckhout, the action is similar to that of the bromides. Takeda (*A. I. P. T.*, 1911, xxi, p. 203) has, however, shown that only a small percentage of the molecule is decomposed in the body, and believes that the drug acts as bromural, not as its constituent parts.

While it is often of service in the milder types of *insomnia*, in severer cases bromural is an uncertain hypnotic. Its most important use is as a general nerve sedative, for which purpose it appears to combine the sedative actions of both the bromides and valerian. Like the bromides it has a certain amount of anodyne power in *neuralgic* pains and like valerian is useful to control the various *hysterical* manifestations. It appears, also, according to the experience of Ferrata and Golinelli (*Gaz. Internaz.*, 1908, No. 13), to exercise the motor sedative effect of the bromides in *epilepsy*. It has also been recommended as a sedative in *asthma*, in *whooping cough*, and for *sea-sickness*. The *dose* of bromural, as a sedative, is from five to ten grains (0.32–0.65 Gm.) several times a day, as may be required, as a hypnotic from ten to twenty grains (0.65–1.3 Gm.) should be administered immediately before retiring. It may be prescribed either in the form of a tablet or as a powder enclosed in a capsule.

Brovalol. *Brom-iso-valeric Acid Borneol Ester. Bornyl Brom-valerate. Valisan.* $CH_3CH(CH_3).CHBr.CO.O.(C_{10}H_{17})$.—A colorless, oily liquid, having a slightly aromatic odor, prepared by esterification of borneol with brom-isovaleric acid or its derivatives. It contains 25.2 per cent. bromine. Brovalol has been used as a nerve sedative in the same type of cases in which valerian is employed. It appears on the market in "pearls," each of which contains four grains (0.25 Gm.). The *dose* is one to three pearls, repeated as required.

Burgundy Pitch. *Pix Burgundica. Poix de Bourgogne, Poix des Vosges, Poix jaune,* Fr. Cod. *Poix blanche,* Fr. *Burgundisches Pech, Burgunder Harz, Wasserharz,* G. *Pece di Borgogna,* It. *Pez de Borgoña,* Sp.—Under the name of *Pix Burgundica* was formerly recognized both by the British (1898) and by the U. S. (1890) Pharmacopœias, "the resinous exudation obtained from the stem of the *Picea excelsa* Link., melted and strained." *Br.*, 1898.

Picea abies (L.) Karst. or *P. excelsa* Link. (Fam. *Pinaceæ*), commonly known as *Norway spruce*, is a lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, standing thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green color, and shining on the upper surface. The male aments are purple and axillary, the female of the same color, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges. This tree is a native of Europe and Northern Asia, and is cultivated in the United States as a shade tree. Commercially Burgundy pitch is derived not only from the Norway spruce, but also from the *Abies picea* or European silver fir tree. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, or perpendicular grooved channels are cut, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the east of France, although whether it was ever produced in that province is uncertain. It is chiefly collected in Finland, the Schwarzwald, Austria, and the Bernese Alps. A *factitious Burgundy pitch* is made by melting together common pitch, rosin, and turpentine, and agitating the mixture with water, which gives it the requisite yellow color. Its odor is different from that of the genuine. Hanbury gives as a test of true Burgundy pitch that it is almost entirely soluble in twice its weight of glacial acetic acid while the factitious article similarly treated forms a turbid mixture quickly separating into a thick oily liquid above and a bright solution below.

The resinous exudation from *Pinus sylvestris* is sometimes offered as Burgundy pitch, but Hirschsohn (*Ph. Z. R.*, xxiv) states that it is possible to distinguish the resin of *Picea excelsa* by its being only partially soluble in ether, chloroform, and solutions of salts of ammonium, sodium carbonate, and borax, which dissolve completely the resin of *Pinus sylvestris*. The resin of *Picea excelsa* is also precipitated by the addition of water from its sulphuric acid solution in red violet flakes, while *Pinus sylvestris* resin precipitates white.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state, according to the U. S. P., 1890, it is "hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish-brown or yellowish-brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter. It is almost entirely soluble in glacial acetic acid, or in boiling alcohol, and partly soluble in cold alcohol." *U. S.*, 1890. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil. Instead of the sylvic acid of ordinary rosin, it contains an isomeric acid, which has been called *pimaric acid*, melting at 148° to 149° C., difficultly soluble in cold but readily soluble in boiling alcohol, and also soluble in ether. According to Perrenoud, its formula is $C_{40}H_{54}O_4$, but Vesterberg (*B. Chem. G.*, 1885, 1886 and 1887) showed it to be a mixture, and prepared from it two isomeric crystalline acids, a *dextropimaric acid,* and a *lævopimaric acid,* both of the formula $C_{20}H_{30}O_2$; with these is mixed a varying amount of an amorphous resin acid known as *pinic acid.*

When applied to the skin, as a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight inflammation without separating the cuticle. Sometimes it excites a papillary or vesicular eruption, and we have known it to act as a violent irritant, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in chronic *rheumatic pains,* and in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion of the skin.

Burra Gookeroo or *Burra Gokhroo.*—Under this name, in India, the fruit and sometimes the whole plant of *Tribulus terrestris* L., an annual herb belonging to the *Zygophyllaceæ,* is used as a diuretic and aphrodisiac. The carpels have been commended in London as a remedy in *nocturnal emissions; dose* of fluidextract, from twenty minims to one fluidrachm (1.3–3.75 cc.). The fruits of an allied species, *T. alatus* Delile are used for similar purposes.

Butesin. *N. N. R.* 1924. *Normal Butyl-para-aminobenzoate.* $C_6H_4NH_2.COO(C_4H_9)$.—This is a white, odorless, tasteless powder, soluble in alcohol, but almost insoluble in water. It is a local anesthetic, similar in action to benzocaine. It is used chiefly as dusting-powder but also as ointment or troches.

Butesin Picrate has been used for somewhat similar purposes especially in ointments.

Butyn. *N. N. R.* 1924. Paraminobenzoyl-gammadinormalbutyl-aminopropanol sulphate $[NH_2.C_6H_4.COO(CH_2)_3.N(C_4H_9)_2]_2.H_2SO_4$.—This substance, which is chemically related to procaine, occurs as a colorless, odorless, solid hygroscopic soluble in less than its own weight of water. From its aqueous solution the free base is precipitated by alkalies as a colorless oil.

The reports of Bulson (*J. A. M. A.*, 1922, lxxviii, p. 343) and of Schmitz and Loevenhart (*J. P. Ex. T.*, 1924, xxiv, 167) indicate that butyn is a more active local anesthetic than either cocaine or procaine. It is, however, distinctly more toxic than procaine. It is recommended as a local anesthetic for the eye in strengths of about 2 per cent. It does not affect the pupil nor the local circulation.

Buxus. *Buxus sempervirens* L. *Evergreen Box.* (Fam. *Buxaceæ.*)—This evergreen shrub is too well known to require description. Though much cultivated in this country as an ornamental plant, it is a native of Europe and Western Asia. The wood is considered diaphoretic in its native countries, and is used in decoction in *rheumatism, secondary syphilis,* etc. The leaves, which have a peculiar odor and a bitter and disagreeable taste, are said to be purgative in the *dose* of a drachm. A volatile oil distilled from the wood has been given in *epilepsy.* A tincture formerly enjoyed some reputation as an antiperiodic. (Mérat and De Lens.) The alkaloid *buxine,* which has been discovered in the leaves of this tree, is identical with the bebeerine of nectandra bark. (See *Bebeeru.*) Pavia obtained a second alkaloid, which was investigated by Pavesi and Rotondi. (*Jahresberichte,* 1874, 903.) They named it *parabuxine,* and ascribe to it the formula $C_{24}H_{48}N_2O$. Barbaglia (*A. J. P.*, 1885, 145) described still another alkaloid, *parabuxinidine.* It crystallizes in thin, colorless prisms, is insoluble in water, soluble in ether, freely soluble in alcohol, and colors turmeric paper deep red.

Caapi.—According to Rusby the root and rhizome of the *Banisteria Caapi* Spruce (Fam. *Malpighaceæ*), a woody vine growing along the Amazon, is used as a ceremonial drink by the natives to stimulate fortitude during ordeals. The experiences of Gordon MacCreagh indicate that the drug is a powerful mental and motor stimulant. According to Dr. O. E. White the same drug is known in Bolivia under the name of *ayahuasca.* (See Rusby, *J. A. Ph. A.*, 1924, xiii, 98.)

Cabbage-Tree Bark. *Ecorce de Geoffre,* Fr. *Kohlbaumrinde, Wurmrinde,* G.—The bark of *Vouacapoua inermis,* Sw. (*Andria inermis* H. B. K.) This is a leguminous tree, a native of Jamaica, and other West India islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a brownish-ash color, scaly, and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable odor, and a sweetish, mucilaginous bitterish taste. The cabbage tree contains an alkaloid which has been variously named *jamaicine, andirine, ratanhine* and *surinamine,* but which appears to be *methyl-tyrosine* (see Johnson and Nicolet, *Am. Chem. J.*, 1912, xlvii, p. 459). Two grains (0.13 Gm.) of it produced violent purging in pigeons.

Cabbage-tree bark is cathartic, and, in large doses, prone to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water be drunk during its operation, and may be relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling *lumbrici;* but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The *dose* of the powder is from twenty to thirty grains (1.3–2.0 Gm.); of the extract three grains (0.2 Gm.).

On the continent of Europe the bark of *Vouacapoua retusa* Poir, which grows in Surinam, has also been used. It is considered more powerfully vermifuge and less liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, and very tenacious, and when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon color.

Theodore Peckoldt says of the wood of an allied species, *Vouacapoua Anthelmia* (Vell.) O. Ktze, that the workmen engaged in sawing it are prone to be affected with inflammation of the eyes, constriction of the throat, excessive thirst, a bitter, burning taste, a troublesome itching over the body, and sometimes eruptions on the skin. He obtained a yellowish-brown coloring matter which he called *andirin.* This name has also been given to a glucoside said to have been found in *Vouacapoua inermis,* (see *A. J. P.*, 1885, 558), and a peculiar resin of a bitter, acrid taste, to which is due the irritating properties of the sawdust.

Cacodylic Acid. *Acidum Cacodylicum.* $AsO(CH_3)_2OH$.—Cacodylic Acid is a deliquescent, colorless, crystalline, and odorless solid, which is, however, chemically quite stable. It is very soluble in water with an acid reaction. Cacodylic Acid is *dimethyl-arsenic acid;* that is, arsenic acid in which two hydroxyl radicles have been replaced by two methyl radicles. In the metallic cacodylates the hydrogen in the remaining hydroxyl is replaced by the base; sodium cacodylate is, therefore, $As(CH_3)_2OONa$. The physiological and medicinal properties of Cacodylic Acid are the same as those of sodium cacodylate. (See Part I.) It is, however, rarely used except in the form of one of its salts.

The following preparations have been suggested:

Calcium Cacodylate. Calcii Cacodylas N. N. R. 1924. $[(CH_3)_2AsO_2]_2Ca$ + aq.—A white powder, soluble in water. It contains from 44 to 48 per cent. of arsenic in the form of cacodylic acid and is free from arsenates, arsenites and other arsenic containing compounds. *Dose,* one-half to one grain (0.03–0.06 Gm.).

Guaiacol Cacodylate.—A reddish-white crystalline mass, which dissolves in alcohol and parts with cacodylic acid in the presence of water. Dissolved in oil it has been employed hypodermically in *tuberculosis.* From one to one and a half grains (0.065–0.096 Gm.) may be exhibited every other day.

Ferric Cacodylate. Iron Cacodylate. Ferri Cacodylas. Ferricodil.—Ferric cacodylate is a grayish-brown powder with an apple-like odor, soluble in 16 parts of water, more soluble in hot water but less so in alcohol. It contains from 40 to 45 per cent. of arsenic in the form of cacodylic acid. This salt has been specially recommended by Gilbert and Lereboullet (*R. T.,* 1900, No. 16) for hypodermic use in the treatment of *leukemia, lymphadenoma,* and other serious *anemias.* Montgomery (*J. A. M. A.,* 1916, lxvi, p. 491) calls attention to the fact that iron cacodylate even when given hypodermically may cause the disagreeable garlicky odor of the breath. It is too irritant to be used in concentrated solution, but as much as one grain (0.065 Gm.) dissolved in half a fluidrachm (1.8 cc.) of water may be injected daily. The *dose* by mouth is one to two grains (0.06–0.12 Gm.) several times a day, hypodermically one-sixth to one-half grain (0.01–0.03 Gm.) may be given once a day.

Lithium Cacodylate. Lithii Cacodylas. $(CH_3)_2AsO_2Li$ + aq.—A light, white powder, soluble in water. *Dose,* one-half to two grains (0.032–0.13 Gm.).

Magnesium Cacodylate. Magnesii Cacodylas. $[(CH_3)_2AsO_2]_2Mg$ +aq.—A white powder, soluble in water. *Dose,* one-half to two grains (0.032–0.13 Gm.).

Mercury Cacodylate. Hydrargyri Cacodylas. $[(CH_3)_2AsO_2]_2Hg$.—White crystals freely dissolving in water, but sparingly soluble in alcohol. The solution of pure mercury cacodylate is unstable and locally irritant, and there has been introduced, under the same name, a double salt formed with sodium chloride. Mercury cacodylate is used in the treatment of *syphilis.* Its supposed advantage is in the belief that the cacodylic acid exercises some direct remedial action in syphilis, and will therefore enhance the effects of the mercury. It is generally administered hypodermically in the form of a 5 per cent. solution of which eight to fifteen minims (0.5–0.9 cc.) may be given daily, representing one-third to three-fourths of a grain (0.025–0.05 Gm.).

Potassium Cacodylate. Potassii Cacodylas. $(CH_3)_2AsO_2K$ + aq.—Small, white crystals, soluble in water, but sparingly soluble in alcohol and insoluble in ether.

For description of salts of this acid with quinine and strychnine see *Quinine Cadodylate* and *Strychnine Cacodylate.*

Cacur.—This is a small gourd which, while still unripe, is used by the Kaffirs as an emetic, and which, according to Oliver, is yielded by the *Cucumis myriocarpus* Naud. (Fam. *Cucurbitaceæ.*) G. A. Atkinson (*A. J. P.,* 1887) obtained from it a neutral resinous body, *myriocarpin,* and found that twenty grains (1.3 Gm.) of the fresh pulp produced in man nausea and slight purgation. (*Ed. M. J.,* July, 1886.)

Cadmium. *Kadmium,* G. Cd = 112.4.—This metal is associated with zinc in its ores, occurring principally as *greenockite* (CdS), a yellowish incrustation upon *zinc blende* (ZnS), and, being more volatile than that metal, comes over with the first portions of the zinc in the process for obtaining it. (See *Zincum.*) The cadmium is separated by dissolving the alloy metals in diluted sulphuric acid, precipitating the sulphate by hydrogen sulphide, treating the precipitates with hydrochloric acid, and again precipitating with ammonium carbonate. The cadmium carbonate thus obtained, after being washed and dried, is mixed with charcoal, and exposed to a dull red heat in an earthen retort, when the reduced metal distils over.

Cadmium is a white metal, resembling tin, but somewhat heavier and more tenacious. Like that metal, it crackles when bent. Its sp. gr. is 8.7, melting point from 316° to 320° C. It is little affected by the air, but, when heated, combines with an atom of oxygen to form the oxide, CdO, which forms salts with the acids. The soluble cadmium salts give white precipitates with hydroxides, carbonates or phosphates; and yellow precipitates with soluble sulphides or chromates; with zinc metallic cadmium is precipitated.

Medicinal Uses of Cadmium.—It is probable that the insoluble preparations of cadmium are not actively poisonous, but it is certain that the soluble preparations are corrosive poisons, causing in overdoses giddiness, vomiting, purging, slowing of the pulse and respiration, loss of consciousness, and spasm. In three cases in which the carbonate is said to have been inhaled, the chief symptoms were constriction of the throat, embarrassed respiration, vomiting and purging, giddiness, and painful spasms. (*Ann. Thér.,* 1859.) For a case of poisoning by the *bromide,* see *B. M. S. J.,* 1876.

It has been shown by Athanasius and Langlois (*C. R. S. B.,* 1895, ii,) that the soluble salts of cadmium arrest lactic fermentation. When given hypodermically they produce symptoms similar to those caused by zinc salts, than which, however, they are less powerful; the symptoms are rapid loss of voluntary motion with persistence of the reflexes and pronounced cardiac depression. In the higher animals there is destruction of the red blood corpuscles.

Cadmium Iodide. Cadmii Iodidum. (CdI_2.) *Cadmium Iodatum. Iodidum Cadmicum. Iodure de Cadmium,* Fr. *Jodcadmium, Kadmiumjodür,* G.—Cadmium iodide may be prepared by mixing iodine and filings of cadmium in a moist state, or by dissolving the metal in hydriodic acid, or by double decomposition between potassium iodide and cadmium sulphate. It is soluble in water and alcohol, and may be crystallized from either solution, in large, white, transparent crystals, in the form of six-sided tables, of a pearly luster. These are permanent in the air, melt at 404° C., forming an amber-colored liquid, and give off violet vapors at a dull red heat. The salt is freely soluble in water and in alcohol, and the solution has an acid reaction.

Cadmium iodide was introduced by A. B. Garrod as an external remedy in the treatment of *scrofulous glands, nodes, chronic inflammation of joints,* and various *cutaneous diseases.* The ointment, which was formerly official in the British Pharmacopœia under the name of *Unguentum Cadmii Iodidi* (sixty-two grains to one ounce of simple ointment), is soft, white, and said to readily yield its iodine to absorption when applied by persistent gentle friction.

Cadmium Nitrate.—H. C. Demming recommends a solution of this salt as an insecticide. (*Proc. Penna. Pharm. Assoc.*, 1909, 240.)

Cadmium Salicylate. Cadmii Salicylas. $Cd(C_7H_5O_3)_2 + H_2O$.—Prepared by acting on cadmium oxide with salicylic acid. It is colorless and crystalline, soluble in 24 parts of boiling water, and in alcohol, ether, and glycerin. It is used as an antiseptic.

Cadmium Sulphate. Cadmii Sulphas. Cadmium Sulfuricum. Sulfas Cadmicus. Sulfate de Cadmium, Fr. *Schwefelsaures Cadmiumoxyd, Kadmiumsulfat,* G. $CdSO_4.4H_2O$.—Cadmium sulphate crystallizes in oblique prisms with rhomboidal bases, which are transparent and colorless, and resemble those of zinc sulphate. The ordinary crystals of cadmium sulphate have the formula $CdSO_4.8H_2O$, and, at very low temperature, $CdSO_4.7H_2O$. They have an astringent, slightly acidulous, and harsh taste, effloresce on exposure to the air, and are very soluble in water. The solution, even though acidulated, gives with hydrogen sulphide a yellow precipitate, becoming orange-yellow, of cadmium sulphide, which is dissolved by strong hydrochloric acid, but is insoluble in solutions of potassium hydroxide or ammonia, and is thus readily distinguished from arsenic sulphide. Zinc precipitates cadmium in the metallic state from the solution. Cadmium suspended in a solution of copper sulphate precipitates that metal, leaving cadmium sulphate in solution, and this has been proposed as a method of obtaining the salt. For method of manufacture and tests of purity of cadmium sulphate, see *U. S. D.*, 19th edition, p. 1425.

Cadmium sulphate has been used as a local astringent and stimulant in *diseases of the eye* and in *gonorrhea.* It is employed either in solution, from half a grain to four grains to the fluidounce of distilled water, or in ointment, twelve grains to the ounce of simple ointment.

Cæsium. $Cs = 132.81$.—The physiological effect of cæsium chloride has been investigated by S. Botkin (*In. Dis.*, St. Petersburg, 1888.) He finds that it increases the blood pressure and retards the heart movements to a slight extent. Laufenauer (*Th. M.*, 1889) states that cæsium bromide theoretically ought to, and practically does, control *epilepsy* better than do the ordinary bromides. The physiological and medicinal properties of *rubidium* have also been studied by these investigators and found to resemble those of cæsium.

Cæsium and Ammonium Bromide ($CsBr + 3NH_4Br$).—A white, crystalline powder, readily soluble in water, given in *doses* of fifteen to forty-five grains (1–3 Gm.) in the treatment of *epilepsy.*

Caffeine Arsenate.—A white powder soluble in hot water, used in *neuralgia* and as a cholagogue in certain forms of *jaundice. Dose,* one-sixtieth to one-thirtieth of a grain (0.001–0.002 Gm.).

Caffeine Hydrobromide. *Caffeine Bromide. Caffeinæ Hydrobromidum. Caffeinum Hydrobromicum. Koffeinhydrobromat, Bromwasserstoffsaures Koffein,* G. $C_8H_{10}O_2N_4.HBr + 2H_2O$.—In the form of transparent crystals, readily decomposed but more stable than the hydrochloride. When heated to 110° C. the hydrobromic acid is driven off. Its aqueous solution is very unstable. Used for *nervous headaches* and as a diuretic, injected subcutaneously. *Dose,* one to three grains (0.06–0.2 Gm.).

Caffeine Hydrochloride. *Caffeinæ Hydrochloridum. Caffeinum Hydrochloricum. Koffein-hydrochlorat, Salzsaures Koffein,* G. $C_8H_{10}O_2N_4HCl + 2H_2O$.—Large, colorless, prismatic crystals, readily decomposed by washing with alcohol or water or by long exposure to the air, when water and chlorine are lost. If heated to 110° C. the chlorine is driven off. The normal salt contains about 73 per cent. of caffeine. *Dose,* one to three grains (0.06–0.2 Gm.).

Caffeine Nitrate. *Caffeinæ Nitras. Caffeinum Nitricum. Koffeinnitrat, Salpetersaures Koffein,* G. $C_8H_{10}O_2N_4.HNO_3 + H_2O$.—In the form of yellowish crystals, quickly decomposed by water and alcohol. The salt contains about 70 per cent. of caffeine and all the nitric acid is driven off at a temperature of 100° C. *Dose,* one to three grains (0.06–0.2 Gm.).

Caffeine Salicylate. $C_8H_{10}O_2N_4.C_7H_6O_3$.—White, crystalline masses, soluble in water and alcohol, its solutions, however, undergoing rapid decomposition. It is intended to produce the combined action of its constituents, but the proportion of salicylic acid is too small to exert any perceptible effect. The *dose* is two to four grains (0.12–0.25 Gm.).

Caffeine Sulphate. *Caffeine Sulphas. Caffeinum Sulfuricum. Koffeinsulfat, Schwefelsaures Koffein,* G. $C_8H_{10}O_2N_4.H_2SO_4$.—The sulphate may be made by dissolving caffeine in alcohol, containing more sulphuric acid than is needed to make the salt, and setting the solution aside to crystallize. It is decomposed by alcohol or water alone. The salt contains about 66 per cent. of caffeine. It is used for the same purposes and in the same doses as caffeine. *Dose,* one to three grains (0.06–0.2 Gm.).

Caffeine Triiodide. *Caffeine diodo-hydriodide. Diiodocaffeine.* $(C_8H_{10}O_2N_4.I_2HI)_2 + 3H_2O$.—This occurs in dark green, prismatic crystals soluble in alcohol and water with decomposition. It is used in place of potassium iodide, in the treatment of *rheumatism.* The *dose* is from two to four grains (0.13–0.26 Gm.). It is incompatible with acids.

Cahinca. *David's Root. Radix Caincæ. Cainca,* Fr. *Kainkawurzel,* G.—This medicine attracted at one time considerable attention. The name of *Cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta,* or *black root.* It is derived from the *Chiococca racemosa* L. (Fam.

Rubiaceæ), and perhaps other species of the genus. The virtues of the root reside almost exclusively in its bark. Four distinct principles were discovered in it by Pelletier and Caventou—(1) a crystallizable, bitter substance, believed to be the active principle and called *cahincic acid*, $C_{40}H_{64}O_{18}$ (also called *caïncic acid* and *caïncin*); (2) a green, fatty matter of a nauseous odor; (3) a yellow coloring matter; and (4) a colored viscid substance. Rochleder and Hlasiwetz found also caffetannic acid. Cahincic acid when treated with diluted hydrochloric acid is decomposed into glucose and other products, of which is obtained at first *chiococcaic acid*, $C_{28}H_{42}O_7$ (thought by some to be identical with *quinovic acid*), and later, by boiling with alcoholic hydrochloric acid, *caïncetin*, $C_{22}H_{34}O_3$.

Cahinca is tonic, diuretic, purgative, emetic, and is capable of producing serious gastro-intestinal irritation. In Brazil it has long been used by the natives as a remedy for the *bites of serpents*, also in *rheumatism* and in *dropsy*. *Dose*, of the powdered bark, from twenty grains to a drachm (1.3–3.9 Gm.); of the aqueous or spirituous extract, from ten to twenty grains (0.65–1.3 Gm.). For further information see *U. S. D.*, 20th ed., p. 1295.

Calamus. *U. S. VIII. Sweet Flag. Radix Calami Aromatici. Radix Acori. Sweet Sedge* (*Cane, Rush, Root* or *Myrtle*). *Myrtle-flag* (*Grass* or *Sedge*). *Acore Vrai*, Fr. Cod. *Acore Odorant*, Fr. *Rhizoma Calami*, P. G. *Kalmus, Kalmuswurzel*, G. *Calamo aromatico*, It., sp.—"The unpeeled, dried rhizome of *Acorus Calamus* Linné (Fam. *Araceæ*)." *U. S. VIII.* The sweet flag, or Calamus, has a perennial, horizontal, jointed, somewhat compressed rhizome, from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish roots from its lower surface, and groups of brown fibers resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular leaf scars of light brown and rose color. The leaves are all radical, sheathing at the base, very long and sword-shaped. The scape or flower stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. The fruit is an oblong capsule, divided into three locules, and containing numerous oval seeds.

This plant grows abundantly in the wet places throughout the United States, Europe, Western and Southern Asia. The leaves as well as the rhizome have an aromatic odor; but the rhizome only is employed. It should be collected late in the autumn, or in the spring. After removal from the ground, the rhizomes are washed, freed from their roots, and dried with a moderate heat. Most of the commercial article has the outer portions of the cortex removed. By drying they lose nearly one-half their diameter, but are improved in odor and taste.

Calamus was officially described as follows: "Rhizome 1 to 2 cm. thick, usually in longitudinally split pieces of various lengths; when entire cylindraceous and somewhat vertically flattened, externally reddish-brown, somewhat annulate from remnants of leaf-sheaths; upper surface with triangular leaf-scars, the lower surface with circular pitted scars of roots; fracture short, showing numerous oil cells and scattered fibrovascular bundles, the latter crowded within the endodermis; odor aromatic; taste pungent and bitter." *U. S. VIII.*

The odor of Calamus is strong and fragrant; its taste warm, bitterish, pungent, and aromatic. From 100 parts of the fresh root of the European plant, Trommsdorf obtained 0.1 of volatile oil. The volatile oil is contained in all portions of the plant, the leaves yielding to distillation, according to the analysis of Schimmel & Co., 0.2 per cent., the fresh root 1.5 to 3.5 per cent., the dried German root 0.8, and the Japan root as much as 5 per cent.

The oil is at first yellow, but ultimately becomes red, and has the odor and taste of Calamus. Kurbatow (*Ann. Ch. Ph.*, vol. clxxiii, p. 4) examined *oil of calamus*, and found that the portion boiling below 170° C. yielded, after treatment with sodium, a terpene, having a sp. gr. .8793 at 0° C., and having a boiling point of 158° C. The extractive matter has an acrid and sweetish taste. H. Thomas (*A. Pharm.*, 1886, p. 465; *P. J.*, 1886, p. 1085) obtained from Calamus rhizomes a bitter glucoside, *acorin*, in the form of a clear, thick, yellow liquid, having a neutral reaction and having the formula $C_{36}H_{60}O_6$, splitting into oil of Calamus and sugar. By oxidation *acoretin*, a neutral resin, is formed, and from the extract remaining after the acorin is removed Thomas obtained an alkaloid which he named *calamine*. Calamus is sometimes attacked by worms, and deteriorates on keeping.

Uses.—Calamus is a feeble aromatic and is used chiefly as a household remedy. The volatile oil is largely used in perfumery, and the powdered root itself is esteemed in Ceylon and India as a vermifuge and an insecticide. *Dose*, in substance, fifteen to thirty grains (0.9–1.9 Gm.).

The *fluidextract*, formerly official, *Fluidextractum Calami U. S. VIII*, was given in *doses*, from fifteen to thirty minims (0.9–1.9 cc.).

Calbroben. *N. N. R.*, 1924. *Calcium Dibrombehenate.* $(C_{22}H_{41}O_2Br_2)_2Ca$.—This is a white powder without taste or odor analagous to calcium iodobehenate. It is insoluble in alcohol, water and acetone, soluble in ether and chloroform, and contains after drying 29 per cent. bromine and 3.8 per cent calcium. *Sabromin* and *Asabromine* are proprietary forms of this compound.

The clinical evidence is indisputable that this preparation is capable of exercising many of the therapeutic properties of the alkaline bromides, but there is considerable contradiction as to the extent to which it may replace the older salts. On the one hand, Von Mering (*Med. Klin.*, iv, p. 1464) has found, despite the fact that it contains only one-half the amount of bromine that potassium bromide does, it is equal in power although slower in action, and Bratz and Schlokow (*D. M. W.*, 1909) assert that weight for weight sabromin is more efficacious than potassium bromide. On the other hand, Ellinger and Kotake (*A. E. P. P.*, 1911, lxv) assert that if administered in large enough doses to obtain the bromide action, sabromin is injurious to the kidney, and Bittner (*Pr. M. W.*, 1910) found it of little use in *epilepsy*. It has been employed by many physicians with mostly favorable results in *hysteria, neurasthenia, insomnia, epilepsy*, and other conditions in which the bromides are habitually employed. The *dose* ordinarily given is from eight to thirty grains (0.5–2.0 Gm.).

Calcium Acetate. *Calcii Acetas. Acétate de Chaux*, Fr. *Essigsaurer Kalk*, G. $Ca(C_2H_3O_2)_2$.

—Made by neutralizing acetic acid with precipitated calcium carbonate, evaporating and crystallizing. Colorless needle-like crystals, soluble in water, less so in alcohol.

Calcium Acetyl-Salicylate. *Calcetal. Tylcalsin. Soluble Aspirin.*—This has been introduced under the trade name of *kalmopyrin.* It is a white powder readily soluble in water, differing from the other salts of acetylsalicylic acid in that it is not hygroscopic and its aqueous solution not so rapidly decomposed. It is used as an antirheumatic and analgesic in *doses* of from eight to fifteen grains (0.5–1 Gm.).

Calcium Benzoate. *Calcii Benzoas.* $Ca(C_7H_5O_2)_2 + 3H_2O$.—This salt may be made by adding calcium carbonate to a hot aqueous solution of benzoic acid, filtering, and evaporating the solution, and collecting and drying the crystals, which usually form in beautiful radiating tufts. It is soluble in 18 parts of cold water and 6 parts of boiling water. *Calcium hippurate,* $Ca(C_9H_8NO_3)_2 + 3H_2O$, is made in a similar manner, and is identical in appearance and uses. Poulet recommends the latter highly in the *uric acid diathesis,* for *scrofula,* incipient *cirrhosis of the liver,* and in *struma. Dose,* ten grain (0.65 Gm.).

Calcium Borate. *Calcii Boras.* $Ca_3(BO_3)_2$.—Calcium Borate is prepared by mixing solutions of sodium borate and calcium chloride. It is a white, inodorous, tasteless powder soluble in hot water. It is given internally in *diarrhea,* and used externally as a deodorant and desiccant. *Dose,* ten to fifteen grains (0.65–1 Gm.).

Calcium Chloride Diglycocoll. *Calciglycin,* $(CaCl_2(2NH_2CH_2COOH) + 4H_2O)$.—It occurs as colorless prismatic needles. It is used as a substitute for calcium chloride over which it has the advantage of being non-hygroscopic and comparatively tasteless.

Calcium Creosotate. *Calcreose N. N. R.,* 1924.—This is a dark brown powder with a creosote-like odor and a sharp taste. It appears to be a mixture of creosotic salts of calcium with free calcium hydroxide and carbonate. When mixed with water a portion of calcreose is dissolved yielding an alkaline solution containing the calcium compounds of the phenols of creosote and the insoluble part consisting of the hydroxide and carbonate of calcium.

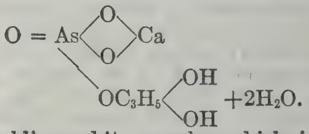
Calcreose is decomposed in the alimentary canal and yields its creosote for absorption and hence may be used for all the therapeutic purposes for which creosote is employed, especially as an expectorant in *tuberculosis, chronic bronchitis,* and the like. It has the advantage over creosote itself of being less irritant to the stomach and may be used in the form of tablets generally without any disturbance of digestion. It represents 50 per cent. of creosote and may be given in doses of from 4 to 16 grains. (0.25–1.0 Gm.).

The term *calcium creosotate* has been also applied to a liquid prepared by mixing creosote with freshly prepared calcium hydroxide in a perculator and then allowing water to run through. It occurs as a reddish-yellow liquid with a creosote-like odor and a sharp, peppery taste, strongly alkaline in reaction. It is asserted to possess the therapeutic properties of creosote and to be much less irritating to the stomach.

Calcium Dithiocarbonate. *Dithio-Calcium Carbonate.* $CaCOS_2$.—An orange-red, crystalline, hygroscopic powder, slightly soluble in water, less so in alcohol. It has been especially employed by Tommasoli and Vicini (*Monatssch. f. Prakt. Dermatol.,* 1892) as a local application in *eczema, psoriasis, lupus, purulent syphilides* and other *skin diseases,* in the form of a 5 per cent. ointment or a somewhat stronger aqueous solution. A 20 per cent. solution produced distinct burning irritation and even pustulation. Sabbatini states that the 1 per cent. solution inhibits, but does not kill pyrogenic micro-organisms. On exposure, its aqueous solution undergoes decomposition with the separation of sulphur and hydrogen sulphide.

Calcium Fluoride. *Calcii Fluoridum.* CaF_2.—A white powder, which is insoluble in water, but becomes soluble in the presence of salts of ammonium. It has been recommended internally by Deninger (*Deutsche Zahnarztliche Wochens.,* 1907, p. 196), during pregnancy, to prevent the loosening of the teeth. It may be given in *doses* of from one-twelfth to one-sixth grain (0.005–0.01 Gm.) twice daily.

Calcium Glycero-arsenate. *Calcii Glycero-arsenas.*



A crumbling white powder which is insoluble in water and alcohol but freely dissolves in mineral and organic acids, especially in a dilute solution of citric acid. According to Schlagdenhauffen and Pagel, the lethal subcutaneous dose of this compound is, for guinea-pigs, 3.10 Gm. per kilo. The preparation is therefore only slightly poisonous and has been employed in daily *dose* of one-sixth grain (0.01 Gm.) internally in *phthisis* by Spillmann and in *diabetes* by Heinrich Stern, in *doses* of 4 to 10 grains (0.26–0.65 Gm.) to be taken three or four times daily.

Calcium Iodate. *Calcii Iodas.* $Ca(IO_3)_2 + 6H_2O$.—This is a white, crystalline powder dissolving in about 400 parts of water. It contains 51 per cent. of iodine and 16 per cent. of available oxygen, which substances are liberated slowly in the presence of putrescent organic matters. It is stated further that in alkaline solution, while the organic matter is being oxidized by the oxygen set free from the decomposing iodate, the iodine slowly reforms iodates by the decomposition of water. The iodate so reformed, in contact with another portion of putrescible matter, yields further proportions of free oxygen and iodine to act as before, and so on. This salt was brought forward by E. Sonstadt as a valuable antiseptic, to be used in the preservation of food. (*Chem. News,* xxviii, 297; confirmed in *Provincial Med. Journ.,* March, 1890.) It is strongly recommended by W. Mackie (*L. L.,* 1900, No. 4035) as a substitute in surgery for iodoform and in internal medicine as a gastro-intestinal antiseptic. The internal *dose* is from three to five grains (0.2–0.32 Gm.) given in capsules after meals.

Calcium Iodide. *Calcii Iodidum. Calcium Iodatum. Iodure de Calcium,* Fr. *Jodcalcium, Calcium Jodid,* G. CaI_2.—According to Malem (*B. G. T.,* April 30, 1868), this salt is preferable to any other iodic compound in *phthisis.* Malem prepares it by treating a solution of ferrous iodide with milk of lime. This liquor thus obtained, being filtered and evaporated, yields crystals of calcium iodide. It may also be made by dissolving lime or calcium carbonate in hydriodic acid.

Pure calcium iodide is white, and crystallizes in large plates of a pearly luster. It is deliquescent, and very soluble in water, and its solution is capable of dissolving iodine added to it. Calcium iodide is much more unstable than potassium iodide. It is incompatible with acids, soluble sulphates, carbonates and tartrates.

Williamson (*B. M. J.*, 1907, p. 909) has found calcium iodide to be especially serviceable in various forms of *ulceration* and *diseases of the skin.* It is also a useful remedy in some cases of *asthma.* The *dose* is from five to ten grains (0.3–0.6 Gm.). The N. F. recognizes a syrup (see *Syrupus Calcii Iodidi,* Part III).

Calcium Permanganate. *Calcii Permanganas. Acerdol.* $CaMn_2O_8$.—This salt probably has the same physiological and medicinal properties as the permanganate of potassium. It has been used in *gastro-enteritis* and *diarrhea* in *doses* of from one-half to one and a half grains (0.032–0.096 Gm.), but has been especially urged for the purification of water. For spring water twenty milligrammes, for river water forty milligrammes, per liter, are recommended. If the color of the water remains red for a short time the permanganate is in excess, as should be the case for effective purification. Calcium Permanganate has also been suggested by Stevens (*K. T. W.*, 1910, p. 166) for the treatment of *lead poisoning.*

Calcium Peroxide. *Calcii Peroxidum.* $CaO_2 + 4H_2O$. *N. N. R.*, 1922.—"A mixture consisting essentially of calcium peroxide and calcium hydroxide and carbonate, containing not less than 60 per cent. of calcium peroxide, equivalent to 13.3 per cent of available oxygen." A yellow, crystalline powder which dissolves but sparingly in water. The solution has an alkaline reaction and possesses a somewhat caustic and astringent taste. In the presence of water Calcium Peroxide splits up into calcium hydroxide and oxygen. It has been brought forward as a powerful oxidizing antizymotic and as an antidote to hydrocyanic acid. In Hornstein's experiments it failed as an antidote unless the cyanide was given in very small quantities and the antidote was administered immediately after the poison. Its germicidal powers appear to be feeble, and its proneness to decomposition is a practical difficulty in its use. It has, however, been highly recommended by Reszkowski (*Gazette Lekarska,* 1899) in the summer *diarrheas* of children, in *doses* of three to ten grains (0.2–0.65 Gm.), administered in milk. It is advised to keep it in parchment capsules in well-stoppered bottles. Under the name of *calcium superoxide* or *gorite* a probably identical oxide has been put on the market. The germicidal influence of gorite was determined by Hornstein (*A. J. P.*, 1901, viii) to be distinctly weaker than that of hydrogen dioxide. Tooth-powders purporting to contain calcium peroxide are upon the market, but in most of them the quantity of the salt present is too small to exercise any therapeutic effect. It is incompatible with acids or acid salts, with soluble phosphates, sulphates and carbonates.

Calcium Phenolsulphonate. *Calcii Sulphophenas. Calcium Sulphocarbolate. Calcium Phenolsulphonate. Karbolsulfosaures Calcium,* G. $[C_6H_4(OH)SO_3]_2Ca + H_2O$.—Made by neutralizing paraphenolsulphonic acid with precipitated calcium carbonate. In the form of a colorless, almost odorless powder, astringent and bitter, readily soluble in water and alcohol. It is incompatible with iron compounds, lead subacetate solution, and peroxides. A 1 per cent. solution is recommended as an intestinal antiseptic, and astringent in *doses* of a fluidrachm (3.75 cc.) every three hours.

Calcium Saccharate.—Under the trade name of *Antacidin* this compound of calcium with cane sugar, $(C_{12}H_{22}O_{11})_3CaO$, has been recommended in the treatment of *dyspepsia* and *flatulency. Dose,* fifteen to sixty grains (1–4 Gm.).

Calcium Salicylate. *Calcii Salicylas.* $CaC_7H_5O_3 + H_2O$.—This compound is the basic calcium salt. It is a sandy, white powder, almost insoluble in water. The neutral salt is also known and is quite soluble in water. Calcium Salicylate has been used in Austria in *doses* of from seven to twenty grains (0.45–1.3 Gm.) for *diarrhea* and *gastro-enteritis.* For method of preparation, see *P. J.*, vol. xxii, 1891.

Calcium Santoninate. *Calcii Santoninas.* $Ca(C_{15}H_{19}O_4)_2$.—This is a white, tasteless, insoluble powder, obtained by saturating hot milk of lime with santonin, and has been brought forward by Bombelen as superior to santonin as a vermifuge on account of its tastelessness, and especially because of its insolubility, which causes it to be absorbed with great slowness. (*Ap. Ztg.*, March, 1899.) *Dose,* one grain (0.065 Gm.).

Calcium Sulph-Ichthyolate.—This preparation, claimed to be more efficient than the ammonium ichthyolate, is made by submitting ammonium sulph-ichthyolate to the action of a solution of calcium chloride in calcium hydroxide solution.

Calcium Sulphate. *Calcii Sulphas Exsiccatus. U. S. VIII. Exsiccated Calcium Sulphate. Dried Calcium Sulphate. Calcii Sulphas,* Br. 1885. *Dried Gypsum. Plaster of Paris. Exsiccated Sulphate of Calcium. Calcis Sulphas. Sulphate of Lime. Gypsum. Calcium sulfuricum ustum,* P. G. *Gebrannter Gyps,* G.—"A powder containing about 95 per cent., by weight, of Calcium Sulphate [$CaSO_4 = 136.14$], and about 5 per cent. of water; prepared from the purer varieties of native gypsum [$CaSO_4 + 2H_2O = 172.17$], by carefully heating until about three-fourths of the water has been expelled. Exsiccated Calcium Sulphate should be kept in well-closed vessels, carefully protected from moisture." *U. S. VIII.* The native sulphate is best known as *gypsum,* and in its massive variety as *alabaster.* Gypsum is an abundant natural product, and the quantity mined in the United States has enormously increased in recent years. It was officially described as "a fine, white powder, without odor or taste. From moist air it attracts water, becomes granular, and then loses the property of hardening with water. When mixed with half its weight of water, exsiccated Calcium Sulphate forms a smooth, cohesive paste, which rapidly hardens. It is soluble in about 378 parts of water at 25° C., and in 451 parts at 100° C. In alcohol it is insoluble. It readily dissolves in diluted nitric or hydrochloric acid; also in saturated solutions of potassium nitrate, sodium thiosulphate, and of various ammonium salts. When heated above 204° C., exsiccated Calcium Sulphate becomes anhydrous and loses the property of forming with water a paste which hardens rapidly. Its saturated solution in water is neutral to litmus paper, and forms white precipitates with barium chloride T.S., with ammonium oxalate T.S., and with alcohol. No effervescence should occur on the addition of diluted acids to exsiccated

Calcium Sulphate (absence of *carbonate*)." *U. S. VIII.*

The solubility of crystallized calcium sulphate, according to Poggiale, varies with the temperature; it is greatest at 35° C. and above or below that temperature gradually diminishes, so that at 100° C., it is very nearly the same as at 5° C. (*J. P. C.*, 4e sér., v, 86.) When deprived of its water by heat, and reduced to the state of a white powder, it rapidly absorbs water added to it, and, from the state of semi-liquid paste into which it is brought with that fluid, hardens without great change of bulk. It is this property which fits plaster-of-Paris so well for all kinds of molding; and to this also it owes its peculiar adaptability to the purpose of a splint. To prepare it for use, the gypsum must first be deprived of the greater part of its water by exposure to a heat of from 100° C. to 121.1° C. It loses both its molecules of water of crystallization at a temperature of about 170° C., and is then known as *burnt gypsum.* If heated above 204° C. it becomes *dead-burnt*, and does not take up water readily and does not harden. When dehydrated, it is reduced to fine powder, and kept in air tight vessels for use. As thus prepared, if mixed with two parts of water, it forms a semi-liquid cream-like mass, which becomes solid and hard in fifteen or twenty minutes, the temperatue rising during the process, as in the slaking of lime. Plaster of Paris sets best when mixed with three-fifths of its weight of water. Colloids retard and crystalline substances hasten the setting; thus, 1 per cent. of salep increases the time of setting from 20 to 50 minutes, while 3 per cent. of alum reduces the time to about five minutes. The hydrated gypsum expands in solidifying, hence its advantages in preparing casts—the expansion causes it to fill accurately all interstices. Cloëz (*Chem. News*, 1903, 58) states that the "setting" of plaster of Paris is due to the succession of three phenomena: (1) Hydration. (2) Partial solution. (3) Solidification of a supersaturated solution.

Gypsum is used, in medicine, chiefly to provide mechanical support or to immobilize various parts of the body. Thus in *fractures* and *sprains* it frequently replaces various forms of splints. Plaster jackets are used to support the thorax in cases of tuberculous diseases of the spine. Ordinarily for surgical purposes it is applied by saturating bandages with the dry powder, these bandages being dipped in tepid water at the time of application. Usually muslin bandages are employed, but, according to T. E. Stark, a medical officer in the British army, flannel is the best material for bandages to be used with gypsum. The bandages should then be rolled up loosely, and kept for use in air tight cases. Dry calcium sulphate has also been recommended as an absorbent dressing in *wounds, foul ulcers* and similar conditions, for which its hygroscopic properties render it valuable.

Cali Nuts.—These nuts, which come from the west coast of Africa, are the seeds of a papilionaceous plant, either a species of *Mucuna* or *Dioclea*, and have a more circular shape than Calabar beans, but otherwise agree with the latter in essential external characters. They contain an alkaloid which is said to be chemically and physiologically closely allied to physostigmine. (Merck, *Chem. Cb.*, 1887.)

Calliandrein.—A glucoside (probably a saponin) obtained from *Calliandra grandiflora* Benth. (Fam. *Leguminosæ*), a Mexican shrub. It is a white, odorless powder soluble in water, the solution forming a heavy froth on shaking. It possesses antipyretic properties, having been administered with asserted good results in *intermittent fever. Dose,* one grain (0.065 Gm.).

Calomelol. *N. N. R.* 1924.—Calomelol is a powder, almost without taste, insoluble in alcohol. It is a colloidal form of calomel containing albuminoids. It is prepared by acting on a solution of sodium chloride in the presence of a proteid with mercurous nitrate, and precipitating the calomel with alcohol. It is asserted to contain 80 per cent. of calomel in the colloidal state and 20 per cent. of albuminoids. It should be guarded from the light and its solution is incompatible with alcohol or alcoholic tinctures and with acids. It is recommended especially for inunction in the treatment of *syphilis.* The advantages over the ordinary mercurial ointment claimed for it are, that it is better absorbed, less likely to cause irritation of the hair follicles, and is almost invisible on the skin. The *calomelol ointment* (*Unguentum Heyden*) contains 45 per cent. of calomelol. The amount applied at one time is ordinarily about ninety grains (5.8 Gm.).

Calotropis. *Mudar. Br. Add.*—The dried root-bark of *Calotropis procera* R. Brown (*Asclepias procera* L.) and of *Calotropis gigantea* R. Brown freed from the outer corky layer. These asclepiadaceous plants are natives of Hindostan, but have become widely naturalized in various parts of the East and West Indies. Their milky juice is a violent local irritant, which, when taken internally, acts as an emeto-cathartic and may produce a fatal gastro-enteritis. In India it has long been used not only for suicidal purposes but to kill newly-born female infants, and is also applied to the womb to cause abortion.

The root-bark occurs in short, more or less quilled pieces having a thickness of from one-tenth to one-fifth of an inch (two to five millimeters) and a width of not more than one and a half inches (thirty-seven millimeters). It is covered with a soft, grayish buff, strongly furrowed and reticulated, easily separated periderm. The fracture is short and mealy; the taste bitter and acrid. According to C. J. H. Warden and L. A. Waddel, calotropis contains an acid resin, a crystalline, colorless substance, *madaralban,* an amber-colored viscid body, *madarfluavil,* and caoutchouc. (*P. J.*, 1885, 165.) Lewin (*A. E. P. P.*, 1913, lxxi, 142) has found a neutral principle (*calotropin*) which is a very active poison of the digitalis type.

Calotropis has been used as a local remedy in Hindostan in *elephantiasis* and *leprosy,* and is asserted by John Morton (*Indian Medical Record,* viii, 1895) to act with extraordinary efficiency upon chronic *eczema.* It has also been employed internally as a remedy in *diarrhea* and *dysentery;* also with less probability of usefulness in *syphilis* and *rheumatism. Dose,* of powder, from three to twelve grains (0.2–0.78 Gm.), three times a day, gradually increased until it affects the system.

Tincture of Calotropis. Tinctura Calotropis. Br. Add., two ounces to a pint (alcohol 6 per cent.), is given in *doses* of one-half to one fluidrachm (1.8–3.75 cc.).

Calycanthus. *Calycanthus floridus* L.—This is a shrub of the Fam. *Calycanthaceæ,* from six to eight feet high, which inhabits the low, shady woods along the mountains of Georgia and North

Carolina, and also Tennessee, where it is known as *sweet shrub* or *Carolina allspice.* The whole plant is aromatic, having, when crushed, the odor of strawberries. According to R. G. Eccles, the seeds contain a fixed oil, and an alkaloid, *calycanthine.* H. W. Wiley (*A. J. P.*, 1890, 96) found in the seeds over 47 per cent. of oil and 4.25 per cent. of alkaloid. H. M. Gordin made an extensive investigation of calycanthine and its salts. (*Proc. A. Ph. A.*, 1905, 224.) According to Cushny (*A. I. P. T.*, 1905, xv, p. 487) calycanthine has the empiric formula of $C_{11}H_{14}N_2$. When injected into the lower animals it causes muscular weakness, by an action upon the peripheral motor nerves, associated with increased reflexes, and, in the higher mammals, with convulsions similar to those seen in picrotoxin poisoning. The alkaloid also exercises a powerfully depressant action upon the heart muscle. Later, a second alkaloid, *isocalycanthine,* was described by Gordin. (*Proc. A. Ph. A.*, 1908 and 1909, 889.) This alkaloid, according to the experiments of MacGuigan and Hess (*J. P. Ex. T.*, 1912, iii), is very similar in its physiological properties to calycanthine. It is asserted that the shrub is important as a source of poisoning to cattle and sheep. Calycanthus has been used as an antiperiodic. The *dose* of the *fluidextract* is thirty to sixty minims (1.9–3.75 cc.).

Calystegia Solandella.—This plant, a member of the fam. *Convolvulaceæ,* has been employed as a cathartic. A compound tincture of solandella has been used with some success, but whether this can be attributed to the calystegia or to other ingredients is not known.

Cam wood.—A red dye-wood, procured from the *Baphia nitida* Lodd., a leguminous tree, growing on the western coast of Africa. The wood is usually kept in the shops in the ground state. When first collected it is white and generally becomes red upon keeping. It yields its coloring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. The coloring matter is thought to be identical with *santalin,* $C_{15}H_{14}O_5$.

Camellin.—A glucoside obtained from the seeds of *Camellia japonica,* $C_{53}H_{84}O_{19}$. It occurs as a reddish-white, bitter powder, soluble in water. It is used as a cardiac stimulant in *endocarditis* and *pericarditis,* several foreign practitioners preferring it to digitalin.

Camphacollasis. *Camphacol.*—This is the *camphoric acid ester of methylene diguaiacol.* It occurs in crystals, and is used as an expectorant in *phthisis* and as an *antiseptic* in *cystitis. Dose,* five to twenty grains (0.32–1.3 Gm.).

Monobromated camphor. Camphora Monobromata, U. S. IX. Bromated camphor, Bromcamphor, "Ortho-monobromcamphor [$C_{10}H_{15}OBr$ or $C_9H_{15}Br.CO = 231.04$]. Preserve it in well-closed containers, protected from light." *U. S. IX.* This substance may be made by heating together bromine and camphor (for details see *U. S. D.*, 20th ed., p. 275). It "occurs in colorless, prismatic needles or scales, or as a powder having a mild but characteristic, camphoraceous odor and taste; permanent in the air. It is decomposed by prolonged exposure to sun-light. One Gm. of Monobromated Camphor dissolves in 6.5 mils of alcohol, 0.5 mil of chloroform, and in 1.6 mils of ether at 25° C.; almost insoluble in water. It melts between 74° and 76° C. Heat a mixture of about 0.1 Gm. each of Monobromated Camphor and silver nitrate and 2 mils each of nitric acid and sulphuric acid until nitrous vapors are no longer evolved; a yellowish precipitate of silver bromide is obtained. Incinerate about 2 Gm. of Monobromated Camphor; not more than 0.05 per cent. of ash remains. Shake about 0.5 Gm. of powdered Monobromated Camphor with 10 mils of distilled water and filter. The filtrate is neutral to litmus and is not rendered more than slightly opalescent by the addition of a few drops of silver nitrate T.S. (*soluble bromide*)." *U. S.*

The therapeutic action of monobromated camphor resembles, but is not identical with, that of the alkali bromides. It can not be given in large enough dose to obtain a full bromide effect without danger of camphor poisoning; epileptiform convulsions have followed its too free use. It is frequently added to the coal tar analysis for the relief of *headaches.* The *dose* is from two to five grains (0.13–0.3 Gm.).

Camphoric Acid. *Acidum Camphoricum. U. S. VIII. Kamphorsäure, Kamphylsaure,* G. $H_2C_{10}H_{14}O_4 = 198.62$.—"A dibasic organic acid obtained by the oxidation of camphor." *U. S. VIII.* This acid is obtained by the oxidation of camphor by heating it with nitric acid, and purifying the crystals so obtained. On further oxidation it is changed into *camphoronic acid,* $C_9H_{14}O_6$. It has been made synthetically by Komppa. (*P. J.*, 1904, 77.)

It occurs in "colorless, odorless, monoclinic prismatic crystals or plates; melting at 187° C.; at a higher temperature yielding an anhydride, and ultimately decomposing without leaving any weighable residue. Soluble in 125 parts of water at 25° C., and in 10 parts of boiling water; readily soluble in alcohol, less soluble in ether and chloroform; soluble in fatty oils. Camphoric Acid is dextro-rotatory, showing in 10 per cent. alcoholic solution, the value $[\alpha]_D = +47.8°$. The aqueous solution reddens blue litmus paper. If 2 Cc. of a saturated aqueous solution of Camphoric Acid be mixed with 2 Cc. of sulphuric acid in a test tube, and 1 Cc. of a solution made by dissolving 1 Gm. of ferrous sulphate in 2 Cc. of diluted sulphuric acid be poured carefully upon it, no dark-colored zone should develop at the line of contact (absence of *nitric acid*)." *U. S. VIII.*

Camphoric acid was at one time used in the treatment of *night sweats* and to a lesser extent in *cystitis,* but both Tyrode (*A. I. P. T.*, 1908, x, p. 393) and Roth (*J. P. Ex. T.*, 1911, ii, p. 405) find that it has no effect on the secretion of either sweat or salivary glands. According to the latter, it is slightly stimulating to the central nervous system, but Tyrode finds that the neutral salts are entirely inert. The *dose* which has been used is from five to fifteen grains (0.3–1 Gm.).

Canada Pitch. *Pix Canadensis. U. S.* 1880. *Hemlock Pitch.*—This is the resinous exudation from the *Tsuga canadensis* (L.) Carr (*Abies Canadensis,* Michx.), *Hemlock* or *Hemlock Spruce,* of the United States and Canada. This tree, when of full growth, is often seventy or eighty feet high, with a trunk of two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. Its leaves are scattered, short, linear, obtuse, from 8 to 13 mm. in length, whitened beneath and appearing as two-ranked. The strobiles are ovate, little longer than the leaves, terminal and pendulous.

The tree is abundant in Canada, Nova Scotia, and northern New England, and is found in the elevated and mountainous regions of the Middle States. Its bark is much used for tanning, an extract being made for the purpose. The tree contains much less juice than some other of the conifers, and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about to, or have begun to decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil. The bark thus incrusted is stripped from the tree, broken into pieces, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. Hemlock pitch is hard, brittle, quite opaque, of a dark reddish-brown color, becoming still darker by exposure to the air, of a weak peculiar odor, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and even at ordinary temperatures takes the form of the vessel containing it, and melts at 92.2° C.

The constituents of this pitch are resin and a minute proportion of volatile oil. It is sometimes known by the incorrect name of *hemlock gum.*

Canada pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from this tree, and called *oil of spruce* or *oil of hemlock,* has been employed to a considerable extent in veterinary liniments.

The U. S. Pharmacopœia of 1880 gave the following directions for preparing the *Hemlock* or *Canada Pitch Plaster* (*Emplastrum Picis Canadensis, U. S.,* 1880): "Canada Pitch, *ninety parts;* Yellow Wax, *ten parts,* to make *one hundred parts.* Melt them together, strain the mixture, and stir constantly until it thickens on cooling." *U. S.,* 1880.

W. Zinn (*M. M. W.,* Oct., 1902) reports a case of stupor and involuntary evacuation of urine, and collapse with subsequent psychic disturbance, as produced by the inhalation for many hours of the emanations from branches of *Pseudotsuga tascifolia* (Lamb.) Britton (*P. Douglassi* Car.).

Canary Seed. *Fructus* (*Semen*) *Canariense, Semence de Canarie,* Fr. *Kanariensamen,* G.—The seeds of *Phalaris canariensis* L., an annual grass originally from the Canary Islands, but now growing wild in Europe and the United States. The seeds are ovate, somewhat compressed, about 5 mm. long, shining and of a light yellowish-gray color externally, and light within. Their chief constituent is starch, and they are used chiefly as bird food.

Canchalagua.—This plant, *Erythræa venusta* A. Gray (Fam. *Gentianaceæ*), found on our Pacific coast, has been used as a bitter tonic and stomachic. (*Ph. Rec.,* 1887, 363.) *Erythræa australis* R. Br. is said to be similarly used in Australia. (*P. J.,* xix.)

Candelilla Wax.—Under this name there has been suggested as a substitute for bee's wax a product of the *Pedilanthus pavonis* Boiss, a Mexican shrub. This plant produces stalks which reach a height of from 3 to 5 feet, a large number of stalks springing from a single root without leaves or thorns. From these are obtained 5 per cent. of a hard wax with a melting point of 67° to 80° C. A sp. gr. of 0.98 to 0.99, an acid value of 12.4 and saponification value of 47 to 65. It is soluble in turpentine and chloroform and has been used for a number of purposes in the arts such as shoe polishes, lubricants and phonograph records and suggested as a substitute for bee's wax in pharmaceutical processes. (See *Ph. Era.,* 1919, lii, p. 13.)

Cangoura.—An evergreen creeper, *Bouea oblongifolia* (Fam. *Anacardiaceæ*), from the seeds of which the natives of Salvador are said to produce a paste which is a violent nerve poison, producing in some cases delirium lasting as long as eight days. (*Nouv. Rem.,* April, 1892.)

Capparis. *Capparis spinosa* L. *Caper-bush.* (Fam. *Capparidaceæ.*)—A low, trailing shrub, growing in the south of Europe and north of Africa. The buds of unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acrid, burning taste, and is considered useful in *scurvy.* The dried bark of the root was formerly official. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It contains *rutic acid* and a volatile substance of garlic-like odor. It is considered diuretic, and was formerly used in *amenorrhea* and *chronic rheumatism.*

Caprokol. (*N. N. R.* 1925) *Hexyl-resorcinol.*—This compound is a resorcinol in which one of the hydrogen atoms of the benzene ring has been replaced by hexyl. It has the formula, therefore, of $C_6H_3(OH)_2C_6H_{13}$. It has been brought forward by Leonard (*J. A. M. A.,* 1924, lxxxiii, p. 2005) as a urinary antiseptic. He finds that it has a phenol co-efficient by the hygienic laboratory method of about 46; that in strengths of one part in 10,000 of urine it kills the *B. coli* in an hour and even in much more dilute solution will destroy the *staphylococcus.* He finds, moreover, that the urine of men taking the drug by the mouth often becomes actively germicidal, and that the effects occur with either acid or alkaline urine. He has employed it in various infections of the urinary tract, such as *cystitis* and *pyelitis* with good results.

The dose advised is from five to fifteen (0.3–1 Gm.) grains three times a day which should be given in enteric-coated capsules to avoid irritation of the stomach.

Capsella. *Capsella Bursa-pastoris* (L.) Medic. *Shepherd's purse. Bourse à Pasteur, Molette,* Fr. *Hirtentäschlein,* G. (Fam. *Cruciferæ.*)—This very common weed in the United States has been naturalized from Europe. Its aerial portion consists of a basal rosette of rarely entire, usually more or less lobed or pinnatifid leaves, from the center of which arises a stem that may attain a length of 20 inches and which bears few lanceolate, auricled or dentate or entire leaves and axillary racemes of white flowers. The fruit is a triangular pod, one-sixth to one-third inch long.

Capsella at one time enjoyed considerable popularity as a uterine stimulant especially in domestic practice. It had disappeared almost from medical notice but in the last few years has been attracting some attention in the treatment of *uterine hemorrhages.* It has been experimentally investigated by Grober (*Ap. Ztg.,* 1915, p. 308) and by Boruttau and Cappenberg (*A. Pharm.,* 1921, cclix,) who both reached the conclusion that it has a stimulating action on the uterine muscles. The latter investigators found that it also produced a lowering of the blood pressure which they attribute to the presence of acetylcholine. In the past the drug has also been used as an antiscorbutic and diuretic. There are several proprietary preparations, ostensibly derived from capsella, upon the market, such as *bursal, thaspan,* etc.

Bombelon, many years ago, asserted the presence of an aklaloid *bursine,* which, however, has been denied by Grimme (*Pharm. Weekblad.,* 1919, lvi, p. 1421) and by Cappenberg (*Ph. Centralh.,* 1921, lxii, p. 751); the former attributes its activity to *bursic acid.* Cappenberg finds in it bases of the choline group and of the nicotine group, also between 0.1 and 0.2 per cent. of tyramine. The plant also yields upon distillation a volatile oil apparently related to oil of mustard. From two to four fluidounces (60–120 cc.) of the freshly expressed juice may be given at a *dose;* or from one-fourth to one-half fluidrachm (0.9–1.8 cc.) of the fluidextract of the dried plant.

Captol. *Chloral Tannin.*—This proprietary preparation is said to be an impure condensation product of tannin and hydrated chloral. It is a brown hygroscopic powder, slightly soluble in cold water, very soluble in hot water and alcohol, not altered by acids but decomposed by alkalies, striking an olive-green color with ferric salts. According to Eichhoff, in *seborrhea capitis* washing the head morning and evening with a 1 to 2 per cent. alcoholic solution of captol is very successful.

Capulincullo.—This drug, derived from the *Rhamnus Humboldtianus* Roem. and Schult. (Fam. *Rhamnaceæ*) of Mexico, is said to be a violent poison, acting like curare. A non-toxic, non-drying fixed oil, tasteless and odorless, is obtained in considerable quantities from the fruit of the tree.

Carana. *Mararo. Gum Carana.*—A resinous substance, in pieces of a blackish-gray color, externally dark brown, internally somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive, like pitch, easily fusible, of an agreeable balsamic odor when heated, and a bitterish resinous taste. (Geiger.) It is said to be derived from *Urotium Carana* (Humb.) L. March (Fam. *Rutaceæ*), a tree growing in Mexico and South America. Geiger refers it also to *Bursera Simaruba* (L.) Sarg. (*Bursera gummifera* L.), of the West India Islands; but the resin of this tree is *résine de Gomari* or *résine de chibou* or *cachibou* of French writers, and is said to bear a close resemblance to the resin *tacamahac.* It is probable that in South America the name *carana* is applied to different products. (*A. J. P.,* xli, 233.)

Carbon Dioxide CO_2.—This gas is used for several purposes in medicine. In solution, it is called carbonic acid, and its popular employment is to improve the taste of disagreeable medicines, especially certain salines, and as a refreshing beverage. *Aqua Acidi Carbonici* (*Carbonic Acid Water,* or *Soda Water* (so-called); *Acidum Carbonicum Solutum, Eau gazeuse simple,* Fr.; *Kohlensaurewasser,* G.), which was formerly official in the U. S. Pharmacopœia, consists of water highly charged with carbon dioxide. It is also used as a mild counter-irritant to the skin in the form of effervescent baths. Certain spas in which there is a supply of naturally carbonated water, such as Nauheim, make these baths a prominent part of the treatment, especialy in cases of circulatory weakness. A formula for preparing these baths is given under *Aqua.*

Another use for carbonic oxide is as an escharotic. Its destructive action depends upon the intense degree of cold produced by the melting of the solidified gas commonly called *carbonic acid snow.* This is prepared by allowing the compressed gas to escape from a cylinder into a cone-shaped felt or woolen receptacle. The rapid expansion of the gas when freed from pressure causes it to solidify in the form of snow which is dished out of the cone with a spoon and pressed into molds of suitable shape. As its melting point is approximately −54° C. when applied to the skin it absorbs an immense amount of heat and almost immediately freezes the area to which it has been applied. The depth and permanency of the results of this freezing depend upon the duration of the application. Superficial freezing of the skin causes complete cessation of all functions and therefore local anesthesia as well as arrest of blood flow. After thorough freezing, as is accomplished with carbonic acid snow, there is probably formed thrombi in the superficial capillaries which lead to a permanent obstruction of the circulation and consequent death of the part. Carbonic acid snow is used with great success for the destruction of various types of neoplasms, as *warts, hairy moles,* and *vascular nevi.* It is also of service in the treatment of *malignant ulcers of the skin* and *epitheliomata.* The duration of single applications is from thirty seconds to one or two minutes, according to the depth of action which is desired. It has long been known that carbon dioxide is a stimulant to the medullary centers causing rise of blood pressure and increased respiration. Henderson and his co-workers (*J. A. M. A.,* 1920, lxxiv, p. 783, and 1921, lxxvii, p. 1065) recommend the inhalations of carbon dioxide as a clinically useful stimulant in the treatment of *surgical shock,* carbon monoxide (*illuminating gas*) poison and similar conditions.

Cardamine. *Cardamine pratensis* L. *Cuckooflower.*—This is a perennial herb of the fam. *Cruciferæ,* with a simple, smooth, erect stem, about a foot in height. The plant grows in Northern Europe and to some extent in wet places and bogs from New Jersey northward to Labrador. Its bitter and slightly pungent leaves are supposed to be antiscorbutic. The seeds are said to contain *myronic acid,* and to yield on decomposition by hydrolysis an oil analogous to oil of mustard. Feist investigated *C. amara* L. and its volatile oil and found *thio-urea.* Kuntze states that two kinds of crystals were isolated, both being forms of thio-urea. (*A. Pharm.,* 1907, 657.) In Europe they are sometimes added to salads. The flowers formerly possessed the reputation of being diuretic, and of being useful in *chorea* and *asthma.*

Carissin.—This is a glucoside which has been isolated from the bark of *Carissa ovata* R. Br. (Fam. *Apocynaceæ*), by J. H. Maiden and H. G. Smith. It is stated to be exceedingly bitter and very poisonous, and in its chemical relations to resemble strophanthin, from which it differs, however, in being precipitated by basic lead acetate and by tannic acid. Its most characteristic reaction is the production of a beautiful emerald-green color on the addition of a minute fragment of potassium dichromate to its solution in concentrated sulphuric acid. (*P. J.,* 1896.)

Carota. *U. S.* 1870. *Carotte,* Fr. *Mohre, Gelbe Rübe,* G. *Daucus Carota* L.—The *wild carrot* (Fam. *Umbelliferæ*) is widely distributed, growing along fences, and in neglected fields and from the beauty of the flowers is often known as *Queen Anne's Lace.* It grows wild also in Europe. The well-known garden carrot is the same plant altered by cultivation. The fruits are very light, of a brownish color, an oval shape, flat on one side and convex on the other, and on their convex surface present four longitudinal ridges, which are beset with stiff whitish hairs or bristles. They have an aromatic odor, and a warm, pungent, and bitterish taste. By distillation they yield about 1.26 per cent. of a yellow to brownish volatile oil, possessing the odor of carrots only to a slight extent. (*Schim. Rep.*, 1907, 31.) Pictet (*B. Soc. Chim.*, 1907, i, 1001) isolated from the leaves of carrots a liquid alkaloid. (*Chem. Ztg.*, 1905, No. 97.) Subsequently two liquid bases, *pyrrolidine* $[(CH_2)_4NH]$ and *daucine* ($C_{11}H_{18}N_2$). Carrot *seeds* are slightly aromatic, moderately excitant and diuretic, and have been employed as a diuretic in chronic *renal diseases* and in *dropsy*. An ounce of them may be given in infusion, in a day. The flowers are sometimes substituted for the seeds, and the scraped root has been used as a local stimulant to sloughing or *indolent ulcers*. For additional information concerning this drug, see *U. S. D.*, 19th edition, p. 1432.

Carthamus. *Carthamus tinctorius* L. *Safflower.*—The *African, false, American,* or *dyers' saffron* is an annual composite, with a smooth, erect stem, somewhat branched at top, and a foot or two in height. The plant is a native of India, the Levant, and Egypt, and is cultivated in those countries, as well as in various parts of Europe and America. The fruit yields 25.82 per cent. of fixed oil, the separated kernels of the seeds 50.37 per cent., according to Fendler. (*Ap. Ztg.*, 1904, 121.) The florets are brought to us chiefly from the ports of the Mediterranean. *Safflower* (*Flores Carthami; Fleurs de carthame, Safran bâtard*, Fr.; *Saflor*, G.; *Cartamo*, It., Sp.) in mass is of a red color, diversified by the yellow of the styles contained within the floret. It has a peculiar, slightly aromatic odor, and a scarcely perceptible bitterness. It contains a fixed oil; also two coloring substances—one red, insoluble in alkaline liquids, and called *carthamin* or *carthamic acid* by Döbereiner, who found it to possess weak acid properties; the other yellow, and soluble in water. Carthamin, $C_{14}H_{16}O_7$, exists to the amount of from 0.3 to 0.6 per cent. only in the safflower, while the safflower-yellow, to which Malin gives the formula $C_{24}H_{30}O_{15}$, is present to the amount of from 24 to 30 per cent. It is the former which renders safflower useful as a dye stuff. Kametaka and Perkins give the formula of carthamin as $C_{25}H_{24}O_{12}$. (*P. J.*, 1910, 299.) The flowers are sometimes fraudulently mixed with Spanish saffron, which they resemble in color, but from which they may be distinguished by their tubular form, and the yellowish style and filaments which they enclose. Unlike Spanish saffron, they do not give a blue color when treated with sulphuric acid.

In large doses carthamus is said to be laxative and, administered in warm infusion, diaphoretic. It is used in domestic practice, as a substitute for saffron, in *measles, scarlatina*, and other *exanthematous diseases*, to promote the eruption. An infusion, two drachms to a pint of boiling water, is usually employed *pro re nata*.

Caruba di Guiden.—Under this name certain gall-like bodies, formed on various species of *Pistacia*, especially *P. Terebinthus* L., as the result of the stings of a hemipterous insect were used for smoking and inhalation in *chronic bronchitis* and *asthma*. They appear to act by exciting free secretion, probably through the turpentine with which they are saturated. For further information, see *U. S. D.*, 20th edition, p. 1306.

Carvacrol. *Isopropyl-o-cresol. Oxycymol.* $C_{10}H_{13}OH$.—A phenol-like body existing in the Trieste and Smyrna *Origanum* oil and some other labiate plants and made artificially from either carvone or camphor. It forms a thick, colorless oil which does not solidify at 25° C., and boils at from 233° to 235° C. For an investigation of *Nitroso-carvacrol*, by Kremers and Brandel, see *Ph. Rev.*, 1904, 248. Cousin and Hérissey prepared from *carvacrol*, *dehydrodicarvacrol* or *dicarvacrol*. (*J. P. C.*, 1910, 2, 49.) Hixson and McKee (*J. Ind. Eng. Chem.*, 1918, x, p. 982) have manufactured carvacrol from spruce turpentine.

According to Martindale, carvacrol is almost as actively germicidal as its isomer, thymol. It has been used in medicine not only for its antibacterial properties, but also as a local anesthetic in *toothache*, cotton saturated with it being inserted into the carious cavity.

The experiments of Sollmann (*J. P. Ex. T.*, 1919, xiv,) and of Livingston (*J. P. Ex. T.*, 1921, xvii, p. 261) have shown that the toxicity of carvacrol on mammals as well as for certain worms is practically the same as that of thymol and the suggestion is made that it would afford a cheap substitute for thymol as an anthelmintic.

Carvacrol Iodide.—*Iodocrol*, $C_{10}H_{13}OI$, is a bulky, grayish-yellow or buff-colored amorphous powder having a faint aromatic odor. It is insoluble in water, slightly soluble in alcohol, soluble in ether, chloroform, petroleum, benzin, carbon disulphide, volatile and fixed oils. From its solution in ether and chloroform it is precipitated on the addition of alcohol, becoming paler in color. This purified product does not show signs of shrinkage until above 170° C., and at 200° C. becomes tarry and black. It is alleged that it combines the antiseptic properties of carvacrol with those of iodine, and possesses the advantage over iodoform in being odorless or nearly so, and in being five times as bulky, It has been used in surgical dressings in *eczema, pruritus, chancres*, and *chancroids*.

Carya. *Hicoria. Hickory.*—Several species of the genus *Carya* Nuttall (*Hicoria* Raf.) grow in the United States of which *Carya illinoënsis* (Wang.) K. Koch bears the *pecan nut*, and grows in the Middle and Southwestern States; *C. ovata* (Mill.) K. Koch, a large and handsome tree known as *shell-bark* or *shag-bark hickory*, is the chief source of the hickory nuts of the market. There are six other common species of *carya* which are indigenous to the United States and Canada, and all yield edible fruits. The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astringent and bitter. In the bark of *H. alba* F. R. Smith found a crystalline principle, *caryin*, which he believed to be quercitrin.

Casearia. *Casearia esculenta* Roxb.—This Indian plant (Fam. *Flacourtiaceæ*) whose leaves are used for a food stuff, is said to be a valuable remedy in *hepatic torpor*, and to contain an organic acid allied to cathartic acid. (*P. J.*, xx.)

Casein.—This substance is one of the important constituents of milk and cheese. It is now made on a large scale in the United States from the "skim milk" obtained from creameries; this is conducted into tanks and heated by steam to 49° C., then coagulated by hydrochloric acid and thoroughly agitated; the *casein* separates into a mass, and the remaining liquid is used in the manufacture of sugar of milk. (See *Saccharum Lactis*, also a paper by C. H. LaWall in the *Alumni Report of the Philadelphia College of Pharmacy*, April, 1902, and one by J. W. England, *Proc. A. Ph. A.*, 1902, p. 357.) Commercial casein is used largely in the sizing of paper and in the manufacture of a glue substitute. It has been proposed by Seger as an emulsifying agent in pharmacy. One gallon of milk is treated with two and a half fluidounces of water of ammonia for twenty-four hours, and, after removing the saponaceous matter from the surface of the mixture, the serum is precipitated with acetic acid. The magma of casein, strongly pressed, is treated with sodium bicarbonate, and with a sufficient quantity of sugar to make the dried product contain one-tenth of its weight of casein. The powdered substance dissolves easily in water, and, mixed with an equal weight of gum, may be used for almost all of the emulsions. Resinous matters and balsams previously dissolved in alcohol, essences, and oils, may be mixed with it in the bottle itself without using the mortar. The only defect in this casein saccharate is its slight odor. The casein of milk prepared by a somewhat similar process to the above is largely used in the preparation of many of the so-called "rolling" creams used for cosmetic purposes.

It is commercially used in the manufacture of foodstuffs, as a fixing agent in calico-printing replacing albumin, as a substitute for glue in cements, as a size in paper manufacture, as a basis for cold water paints, and in the manufacture of plastic compounds, hardened with formaldehyde, such as *galalith.* A prepared casein diabetic flour is on the market in which milk casein is modified by a leavening mixture of sodium bicarbonate and acid calcium phosphate.

Pure casein has a sp. gr. of 1.259. It is readily soluble in 1 per cent. solutions of sodium fluoride, ammonium oxalate, and potassium oxalate, and 5 per cent. solutions of ammonium chloride or sulphate, as well as solutions of alkaline hydroxides, carbonates, borates, etc. Iodine compounds of casein are in use as follows: *periodocasein*, containing 17.89 per cent. iodine; *iodocasein*, containing 15.7 per cent. iodine; and *casein iodine*, containing 8.7 per cent. iodine. Bromine compounds are also known. Metallic casein compounds, as *silver caseinate*, are known and referred to under the appropriate heads. Compounds of casein with alkaloids are prepared by suspending casein in alcohol and adding an alcoholic solution of the alkaloid.

Ammonium Caseinate has been put on the market under the trade name of *Eucasin.* It is a grayish-white powder, with an odor like that of buttermilk, soluble in hot water. Feustell (*D. M. W.*, xxii, 1896) has used it as an accessory food.

Calcium Caseinate N. N. R., 1924, contains between 1.4 and 2.1 per cent. of calcium. It is a pale yellowish fluffy powder which when shaken with water yields a turbid suspension. It is used as an accessory food in *diarrheas* of infancy. Proprietary forms of Calcium Caseinate are known as *Caseo, Larosan-Roche,* and *Protolac.*

Sodium Caseinate. Sodii Caseinas. Nutrose. Casein-natrium, G.—A combination of casein and sodium hydroxide, just enough of the alkali being used to dissolve the freshly precipitated casein. The solution is evaporated *in vacuo*, the dry residue powdered, thoroughly washed with alcohol, and then with ether and dried. A white, amorphous powder, with little odor or taste, insoluble in alcohol and ether, slightly so in cold water, but readily soluble in hot water. It is considered to be a valuable food in intestinal and digestive disturbances, also in *anemia* and *scrofula.*

Casimiroa. *Casimiroa edulis* Llav. et Lex. *Zapote blanco. Cochil Sapote. White Sapota.*—This is a large tree belonging to the *Rutaceæ*, a native of Mexico, the leaves are employed in *diarrhea* and as an anthelmintic. Robin and Coyen (*Press. Med.*, 1909, p. 454) and Chevalier (*B. G. T.*, 1909, clviii, p. 96) have asserted that the Casimoroa seeds are narcotic.

Altamirano obtained from the seeds what he believed to be a glucoside which he called *casimirose* and Bickern (*A. Pharm.*, 1903, ccxli, p. 166) an alkaloidal glucoside which he named *casimirin.* Power and Callan (*Tr. Chem. Soc.*, 1911, xcix, 1093) found two alkaloids *casimiroin* and *casimiroedine*, a small quantity of an agreeable aromatic volatile oil and various other organic substances. Neither the alcoholic extract of the kernels nor any of the principles separated from them possess any physiological action beyond a local irritant effect on the stomach confirming the previous conclusion of Esch and Kochmann (*A. I. P. T.*, 1911, xxi, 353.)

Cassia. *Cassia marilandica* L. *Wild Senna. American Senna. Séné Américain,* Fr. *Amerikanische Senna,* G. (Fam. *Leguminosæ.*)—This is an indigenous perennial plant of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong-lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channelled above, and furnished near its base with an ovate, stipitate gland. The American senna is common from New England to North Carolina. The leaves, which should be collected in August or the beginning of September, are sometimes brought into the market, compressed into oblong cakes. The leaflets are from an inch and a half to two inches long, from one-fourth to half an inch in breadth, thin, pliable, and of a pale green color. They have a feeble odor, and a nauseous taste, somewhat analogous to that of senna. Water and alcohol extract their virtues. Hermann J. M. Schroeter (*A. J. P.*, 1888, 231) found in them chrysophanic acid; also a principle corresponding in all respects with cathartic acid. American senna is an efficient and safe cathartic, acting like senna but more feebly.

Cassia nictitans L., or *Wild Sensitive Plant,* was investigated by Gallaher (*A. J. P.*, 1888, 280), had failed to find any glucoside or alkaloid. The amount of volatile oil found was very small, and cathartic acid could not be prepared from it, although the powder produced griping. The leaves of *Cassia alta* L. are recommended by Conillebault in *ringworm;* they are moistened and the parts affected rubbed with them. (*A. J. P.*, 1887, 266.)

Under the names of *Cheshmat, Chashmizok, Schischen,* the seeds of *C. Absus* L. are said to be used in India and Africa in the treatment of inflammations of the eye, either in the form of a fine powder or an infusion made from the coarsely ground seeds to which several medicinal substances are added.

The root of the *Cassia bearensis* Miq. is said to be very useful in the so-called *black-water fever* of Africa. (See *P. J.*, vols. xlvii, xlviii.)

Castela. *Castela Nicholsoni texana* Torrey and Gray. (Fam. *Simarubaceæ.*)—This plant, which is known among the Mexicans as *Chaparro amargosa*, that is, *bitter bush*, has been highly recommended by Nixon (*J. A. M. A.*, 1916, lxvi, p. 946) in the treatment of amebic *dysentery*. He found that a detannated fluidextract in the proportion of one part in a million was sufficient to cause the *Entamœba histolytica* to become immobile and to assume a spherical shape, with sharp differentiations of ectoplasm and endoplasm. In ordinary diarrhea or in helminthiasis he found the drug of no value. Putegnat (*N. R.*, 1883, xii, p. 102) has separated a bitter principle, *amargosin*, which, however, is of doubtful importance. The conclusions of Nixon concerning the amebicidal effects of chaparra amargosa have been confirmed by Shepheard and Lillie (*L. L.*, April 6, 1918), Seldards and McIver (*J. P. Ex. T.*, 1918, xi, p. 331). The chemical studies of the latter, while not conclusive, suggested the presence of a glucoside. Nixon preferred a decoction of the drug, but the fluidextract is upon the market and may be given in *doses* of one to three fluidrachms (4.0–12.0 cc.).

Castor. *Castoreum. Castoréum*, Fr. *Bibergeil*, G. *Castoro*, It. *Castoreo*, Sp.—In the beaver, *Castor fiber* L., between the anus and external genitals of both sexes, are two pairs of membranous follicles, of which the lower and larger are pear shaped, and contain an oily, viscid, highly odorous substance, secreted by glands which lie externally to the sac. After death, the follicles containing *castor* are removed, and dried either by smoke or in the sun.

This drug is derived either from the northern and northwestern parts of America, or from Russia, and is called in commerce, according to its source, Canadian or American or Russian castor. It is supposed by some that the American and Russian beavers are distinct species, the former being a building, the latter a burrowing animal, and additional ground for the supposition is afforded by the fact that the products of the two differ considerably. Of the Russian castor only a very small portion is imported into this country.

Castor comes to us in the form of solid unctuous masses, contained in sacs about two inches in length, larger at one end than at the other, much flattened and wrinkled, of a brown or blackish color externally, and united in pairs by the excretory ducts which connect them in the living animal. In each pair one sac is generally larger than the other. They are divided internally into numerous cells, containing the castor, which, when the sacs are cut or torn open, is exhibited of a brown or reddish-brown color, intermingled more or less with the whitish membrane forming the cells. Those brought from Russia are larger, fuller, heavier, and less tenacious than the American; and their contents, which are of a rusty or liver color, have a stronger taste and odor, and are considered more valuable as a medicine. A variety of Russian castor, described by Pereira under the name of *chalky Russian castor*, is in smaller and rounder sacs than the American, has a peculiar empyreumatic odor very different from that of the other varieties, breaks like starch under the teeth, and is characterized by effervescing with diluted hydrochloric acid. Müller found 40.646 per cent. of calcium carbonate. According to Kohli, Canadian castor, treated with distilled water and ammonia, affords an orange precipitate, while the precipitate thrown down from the Russian under similar treatment is white.

Good castor has a strong, fetid, peculiar odor; a bitter, acrid, and nauseous taste, and a color more or less tinged with red. It is of a softer or harder consistence according as it is more or less thoroughly dried. When perfectly desiccated, though still slightly unctuous, it is hard, brittle, and has a resinous fracture. Its chemical constituents, according to Brandes, are volatile oil, 2 per cent.; resinous matter, 14–50 per cent.; albumin; a substance resembling *osmazome;* mucus; salicin; cholesterin; calcium urate, carbonate, benzoate, phosphate, and sulphate; sodium acetate and chloride; potassium chloride, sulphate, and benzoate; ammonium carbonate; membranous matter, and a peculiar proximate principle discovered by Bizio, an Italian chemist, and called by him *castorin*. For additional information concerning castor, see *U. S. D.*, 19th edition, p. 1435.

Castor was at one time much used as a stimulant antispasmodic, also as an emmenagogue, but has passed almost entirely out of vogue except in perfumery where the alcoholic solution is used in the same manner as preparations of musk and civet. It may be given in *hysterical affections* in *doses* of ten to thirty grains (0.65–2.0 Gm.), in capsules or emulsion.

A substance allied to castor is the secretion of the anal glands, used for the purpose of defence by the *Mephitis mephitica*, or common *skunk* of North America. According to T. B. Aldrich, this is a neutral, golden-colored liquid, having an extremely penetrating and disagreeable odor, containing mercaptan, allyl-sulphide, and traces of butyl-mercaptan. (*C. D.*, 1897.)

Catalpa. *Catalpa bignonioides* Walt. *Catalpa-tree*, or *Catawba-tree. Indian Bean.*—This is a beautiful indigenous, flowering tree, of the fam. *Bignoniaceæ*, the seeds of which have been employed in *asthma*. Eugene O. Rau obtained from them tannin and a bitter crystalline principle. (*A. J. P.*, xlii, 204.) F. K. Brown obtained from the seeds resin, fixed oil, tannin, sugar, and two crystalline bodies, their exact nature not being determined. (*A. J. P.*, 1887, 230.) I. Schneck states that large doses cause nausea, vomiting, and slow, weak, intermittent pulse. He gave two fluidrachms (7.5 cc.) of the tincture (1 oz. troy to 1 pint) every one to three hours.

Cataplasms. *Cataplasmata. Poultices. Cataplasmes*, Fr. *Umschläge, Breiumschläge*, G.—*Cataplasms*, or poultices, are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighboring parts, or so tenacious as to adhere firmly to the skin. As they are in this country seldom made by the pharmacist they are not deemed by the compilers of the U. S. Pharmacopœia proper objects for official direction. *Cataplasma Kaolini* is official in the National Formulary. (See Part III.)

Catha. *Catha edulis.*—Under various Arabic names, such as *Kât, Khât, Chaat, Kus es Salahin, Tchaad, Tschut, Tohat, Tohai, Gât,* the leaves of

Catha edulis Forsk. (fam. *Celastraceæ*) (*Abyssinian* or *African tea*) are very largely used as a stimulant in Northern Africa, the plant being extensively cultivated.

The plant is a shrub, reaching the height of nine to twelve feet, with thin coriaceous leaves whose margins are bluntly serrate. The rounded grayish-green twigs are, for commercial purposes, dried with the leaves and tied together in bundles containing about forty twigs; the bundles are commonly from twelve to fourteen inches in length and three to four inches in diameter, but sometimes much smaller. The leaves are chewed both in the green and fresh condition, and are in some places made into a tea. The taste is sweetish and astringent, somewhat suggesting licorice. They are asserted to act as stimulants, overcoming the sense of fatigue in the same way as cocaine, or caffeine. Flückiger and Gerrock found in it an alkaloid, *katine*, $C_{10}H_{18}ON_2$, which has been studied by Chevalier (*B. G. T.*, 1912, xviii), who finds that it is a stimulant to the central nervous system. Stockman (*P. J.*, 1912, lxxxviii) found three alkaloids, *cathine*, *cathinine*, and *cathidine*, and also a fourth alkaloid in too small quantities for study. He found (*J. P. Ex. T.*, 1913, iv) that these alkaloids were stimulating to both the brain and spinal cord, and in large doses produced paralysis through a direct action upon the muscle.

Cayaponia. *Cayaponia globosa. Silva Manso.*—This is a cucurbitaceous plant of Brazil, from which Gubler has extracted the alkaloid *cayaponine*, said to purge without griping. *Dose*, one grain (0.065 Gm.). (*Rép. de Pharm.*, 1879, 193.)

Ceanothus. *Ceanothus americanus* L. *New Jersey Tea. Red-root. Céanothe*, Fr. *Seckelblumen-wurzel*, G.—A small indigenous shrub, of the fam. *Rhamnaceæ*, growing from western Ontario and Maine southward. The *root* is astringent, and imparts a red color to water. F. C. Gerlach (*A. J. P.*, 1891, 332) finds 6.48 per cent. of tannin and 0.52 per cent. of an alkaloid to which he gives the name *ceanothine*. J. A. Buckner (*A. J. P.*, 1891, 428) found 9.45 per cent. of tannin in the leaves. Gordon (*Pharm. Rev.*, 1900, xviii) reported the presence of two crystalline alkaloids melting at 200° C. and 255° C. respectively. *Ceanothus* is said to be useful in *syphilis*. Schoepf states that it is purgative. Ceanothine has also been stated to act as a vasoconstrictor and a preparation of the bark has been put upon the market as a hemostatic. The leaves were used during the Revolutionary War as a substitute for tea. The Mexican *C. cœruleus* Lagasca (*C. azureus* Desf.) is used as a febrifuge.

Cecropia Obtusa Trec. (Fam. *Urticaceæ.*)—An extract of these leaves is used as a diuretic, having an action similar to that of digitalis though less toxic than it. *Dose* of the liquid extract, thirty minims (1.8 cc.).

Cedron.—The seeds of the *Simaba Cedron* Planch., a tree growing in Colombia and Central America, belonging to the *Simarubaceæ*. The fruit is a large solitary drupe, containing a single seed. *Cedron* seed is from 3 to 4.5 cm. long, and 1.5 to 2.5 cm. broad, elongated ovate, convex on one side, flat or slightly concave on the other, and presenting an oval scar near one extremity of the flat surface. It is often yellowish, hard and compact, but readily cut with a knife; is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. Lowry (*J. P. C.*, xix, p. 365) separated from what he believed to be the seeds of *Simaba Cedron*, a crystalline substance which he named *cedrin*. Tanret, however, in attempting to confirm his work, was unable to obtain a crystalline substance from this plant, but he did from one closely allied to it, namely, the *S. waldivia*, and believed that Lowry was mistaken in the identity of his crude material. (See *P. J.*, 1908, lxxxi, p. 103.) Cedrin is now an article of commerce in the colorless crystals. It is bitter, slowly soluble in water, more readily so in alcohol or ether.

Cedron has been used in Central America as a remedy for snake bite and Purple has recommended it as an antiperiodic. The *dose* of the crude drug is from five to fifteen grains (0.3–0.9 Gm.). The bitter principle cedrin has been given hypodermically in *doses* of one-fifteenth of a grain (0.004 Gm.).

Celastrus.—Various species of the *Celastraceæ* have medicinal properties. In the East Indies the oil obtained from the seeds of *Celastrus paniculatus* Willd. is used as a powerful stimulant and diaphoretic in *rheumatism*, *gout*, and various *fevers*. The oil is said to be deep reddish-yellow, and to become thick and honey-like on keeping. It is sometimes known as *oleum nigrum*. In Abyssinia, according to Dragendorff, the leaves of *C. serratus* Hochst. (*C. obscurus* A. Rich.) are used as an antiperiodic under the name of *Add-add*. Dragendorff found in them tannic acid, a volatile oil, and a bitter principle, *celastrine*. (*A. J. P.*, xxvi.) In North America the bark of *Celastrus scandens* L. (*climbing staff tree, false bittersweet, fever twig*) has been used in chronic affections of the *liver* and in *secondary syphilis*, and is said to be emetic, diaphoretic, and alterative. C. H. Bernhard found in the bark acid and neutral resin, starch, glucose, gum, a caoutchouc-like body, coloring matter, and volatile oil. (*A. J. P.*, 1882, 1.) Wayne stated that he had isolated from *C. scandens* white minute crystals, to which he gave the name of *celastrine*. According to Ugolino Mosso (*Rivista Clinica*, 1891), celastrine arrests the frog's heart in systole; does not affect markedly the blood pressure in mammals, and influences the respiration only through its action on the vagus. The stimulant action is especially manifest on the brain and is not followed by a secondary depression. There is marked, persistent elevation of the temperature.

Celloidin.—A proprietary purified form of pyroxylin. It is supplied in shreds immersed in water. It is much used in microscopical technique.

Cellotropin. *Monobenzoyl Arbutin.* $C_6H_4.O.C_6H_5CO.O.C_6H_{11}O_5$.—This is prepared by acting upon arbutin with benzoyl chloride. It is a white, odorless and tasteless powder, practically insoluble in water or ether, but freely soluble in alcohol. To this substance Kapp (*Med. Rund.*, 1904) attributes the remarkable quality of being a specific curative in *pulmonary tuberculosis*. He asserts that it exercises direct action on the tubercle bacilli which he believes is probably due to an increase of the bodily enzymes. Its influence is generally manifest within a few weeks. It has also been used in *gastro-intestinal catarrh* and digestive disturbances of children. The *dose* for adults is put down as eight to fifteen grains (0.5–1.0 Gm.).

Cellu Flour. *N. N. R.* 1922.—Commercially pure cellulose in the form of flour, used as a means of filling out reduced diets in the Allen treatment for diabetics. A non-nutritive food substitute used to give bulk to foods.

Celluloid. *Zylonite.*—This material, which has been manufactured into so many useful forms, furnishes an excellent substitute for ivory, tortoise shell, amber, and vulcanite. It is a nitrocellulose, which is made capable of molding into any desired form by the admixture of a small amount of camphor. At the temperature at which the camphor melts, it acts as a solvent for the nitro-cellulose and forms a uniform plastic mass with it. This mass may be used directly in the manufacture of various articles, or it may be admixed with mineral coloring matters so as to imitate the various natural stones. The stratified appearance of ivory and the mottled appearance of tortoise shell and amber are obtained by passing between heated rolls plain and colored or clouded celluloid in alternating layers. The material is combustible when ignited, and in thin pieces burns rapidly with a bright light. For this reason it is a dangerous material from which to manufacture articles of wearing apparel, such as collars, combs, etc. Many of these articles are found on the market made of celluloid and some of these are falsely labeled rubber, ivory, tortoise shell, etc.

Within recent years so-called celluloid varnishes have come into extensive use for lacquering on metal; these are often nothing but pyroxylin solutions in which methyl alcohol, petroleum naphtha, and amyl acetate are used as a mixed solvent.

Cephalanthus. *Cephalanthus occidentalis* L. *Button Bush. Button Wood. Crane Willow. Swamp Dogwood.* (Fam. *Rubiaceæ.*)—A common indigenous shrub which grows in moist places, as along streams or on the borders of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion. (See *M. R.*, 1911, 216.) E. M. Hattan found in it crystallizable fluorescent acid, a bitter uncrystallizable principle, a principle resembling saponin, tannin, two resins, fatty matter, gum, glucose, and starch. (*A. J. P.*, xlvi, 314.) According to Claassen (*Ph. Rund.*, Bd. vii, 1889), the fluorescent acid of Hattan is composed of two substances, *cephalin* and *cephaletin.* Carl Mohrberg has separated from the bark a substance which he knows as *cephalanthin*, and also a toxic saponin-like principle which, like its allied poisons, has the power of dissolving the blood corpuscles. Cephalanthin he finds to be a distinct poison to both cold and warm blooded animals, causing destruction of blood corpuscles with conversion of oxyhemoglobin into methemoglobin, violent vomiting, convulsions, and paralysis. (See *Kobert's Arbeiten*, viii, 1892.)

Ceratopetalum.—The New South Wales species of this genus, viz., *C. gummiferum* Sm. and *C. apetalum* Don., of the *saxifragaceæ*, yields considerable quantities of a kino-like gum. The barks contain coumarin. (See *P. J.*, xxi, 742.)

Cerberin.—The original substance described under this name was obtained from the seeds of the *Cerbera Odallam* Gärtn. (*Apocynaceæ*), but the name has been applied to principles from various allied plants. Under the name of *cerberid* there is upon the market a glucoside obtained from the *Thevetia Ycottli* DC. (*Cerbera Thevetia* L.). This is a yellowish, amorphous powder, with a bitter taste and soluble in water. According to Zotos (*In. Dis.*, Dorpat, 1892), it acts upon the heart like digitalis. Wagner (*Russki Vratch*, 1892, 1033) finds that it is too irritant to the intestinal tract to be clinically valuable. The *dose* is, hypodermically, one one-hundredth of a grain (0.0006 Gm.), by mouth, one-sixtieth to one-thirtieth of a grain (0.001–0.002 Gm.).

Cercis. *Cercis canadensis* L. *Judas Tree. Redbud.*—The bark of this beautiful leguminous tree, indigenous and well-known throughout the Eastern and Central United States on account of its brilliant red-purple flowers, which appear before the leaves, has been highly recommended by Wm. R. Smith as a mild but very active astringent in the treatment of *chronic diarrhea* and *dysentery. Dose,* of the fluidextract, from half to one fluidrachm (1.8–3.75 cc.).

Ceresin. *Ozokerite. Earth-wax. Neft-gil.*—Under this name there has been introduced into commerce, as a substitute for wax, a substance which closely resembles white wax, but which is a natural mineral product. It is found most abundantly in Galicia, on the slopes of the Carpathian Mountains, and also on the Wallachian side of the range, in smaller deposits along the Caspian. A valuable deposit has also been discovered in Southern Utah. It consists of a mixture of solid paraffin with some oxygenated bodies. The crude ozokerite is melted to allow earthy impurities to settle out, is treated with sulphuric acid and alkali, as in the treatment of paraffin, and is clarified by bone black, or, better, the black from the manufacture of potassium ferrocyanide. The refined ozokerite or *ceresin* melts between 58° C. and 80° C., is quite odorless and colorless, and has the appearance of bees' wax. It may be distinguished from the latter by its lower specific gravity (0.753 at 98° C. against 0.822) and its absolute resistance to alcoholic potassium hydroxide, no trace of saponifiable matter being present. F. Metz reports the finding of ceresin, colored with coal tar colors. (See *Ph. Ztg.*, 1904, 1031.) The Galician product is worked chiefly in Vienna and in London, where ozokerite candles are manufactured. (See *A. J. P.*, xlv, 11.) In this country ceresin bottles have replaced the gutta-percha bottles formerly used to contain hydrofluoric acid.

Cervitan. *Eldoform.*—This proprietary compound of tannin and yeast has been brought forward as an astringent for the treatment of various types of *diarrhea.* It is a grayish, tasteless powder, sparingly soluble in water or acid solutions but soluble in alkalies. It is marketed in the form of five-grain (0.3 Gm.) tablets of which from 2 to 3 may be given at a dose.

Cereus.—From *Cereus Cæspitosus* Engl. and A. Gray, Heyl separated an alkaloid, *pectenine*, which, according to Heffter (*A. Pharm.*, 1901, ccxxxix, p. 462), produce both in cold and warm blooded animals tetanic convulsions with heightened reflexes. According to the experiments of Mogilewa, the alkaloid acts upon the isolated frog's heart as a depressant.

From *Cereus pilocereus* (?), Heyl separated the alkaloid *pilocerëine*, which Heffter found to produce in frogs central paralysis with great cardiac depression, and in warm blooded animals to kill by cardiac arrest.

Anthelmintic properties have been ascribed to *Cereus flagelliformis* Miller and to *C. divaricatus* (Lam.) DC.

Cerium. (Ce. Atomic Weight 140.25.)—This metal was discovered in 1803 by Berzelius and Hisinger, and named cerium in honor of the goddess Ceres. It was obtained from a Swedish mineral, formerly, from its great weight, called *heavy stone of Bastnas* (*Bastnas Schwerstein*), but now named *cerite*, after the metal extracted from it. Besides cerite, it has been found in several other minerals, as *gadolinite, orthite*, and *monazite*, etc. It is not easy to obtain it pure in the metallic state, as its oxides and salts are difficult of reduction. Berzelius describes cerium as in the form of pulverulent masses, of a deep chocolate-brown color which exhibit, however, under the burnisher a metallic appearance and a dark gray color. Hildebrand and Norton have since prepared it in large quantity by the electrolysis of its chloride. It is a poor conductor of electricity. Sp. gr. 6.92 at 25° C., melting point 645° C. Heated in the air it takes fire before the point of ignition, and burns vividly, passing to the state of peroxide. At ordinary temperatures it is oxidized, in a moist atmosphere, giving out a strong and disagreeable odor. In water, especially when moderately heated, it rapidly oxidizes, with the evolution of hydrogen and the water does not become alkaline. There are two cerium oxides, Ce_2O_3 and CeO_2. Sulphur and phosphorus combine with it.

For methods of isolating metallic cerium see *U. S. D.*, 20th ed., p. 315.

The cerium compounds were formerly obtained chiefly from cerite, which occurs in considerable amounts in Sweden, and affords at least 50 per cent. of *cerium oxide*. The thorium salts were obtained from the mineral *thorite*, which is found in Norway, and contains about 60 to 70 per cent. of its peculiar earth. The supplies of thorite are not sufficient to even approximately meet the demand for thorium salts required for the incandescent gas mantle industry. At present most of it is made from the mineral *monazite*, which occurs in considerable quantities in North Carolina and in the Province of Bahia, in Brazil. Monazite is a *cerous phosphate*, in which a portion of the cerium is replaced by the other cerite earths. The thorium earth is not an integral constituent of the mineral, and, although quite regularly admixed with it, its amount varies within very broad limits.

Metallic cerium has come into prominence recently as an essential constituent of a class of alloys known as *pyrophoric alloys*, of which ferrocerium is the commonest and cheapest. These are used to set fire to inflammable gases, in what are called mechanical or automatic gas lighters, by means of a shower of bright sparks which is emitted when one of these alloys is filed. This property of certain alloys of cerium and other metals was discovered in 1903 by Welsbach, who found the best results to follow the use of a combination carrying about 65 per cent. of cerium earth metals and 35 per cent. of iron. Other alloys have also been experimented with, the one with zinc being used in practice in connection with automatic lighting mine lamps. The greatest pyrophoric power of any alloy yet experimented with was found to be developed in a platinum cerium alloy, but, of course, this is too expensive for practical use. Various theories have been advanced to explain the reason for the spark producing power of these alloys, it being claimed that the property is due to the presence of nitrides, hydrides, etc. None of these theories have been substantiated and the cause remains a mystery.

Cerium Oxalate. *Cerous Oxalate.*—Under the title *Cerii Oxalas*, the U. S. formerly recognized. "A mixture of the oxalates of cerium, didymium, lanthanum, and other associated elements." *U. S. IX.*

From the existing conditions of the thorium industry, the cerium oxalate of commerce, which, although used medicinally, consists of a complex mixture of the oxalates of cerium, lanthanum, and didymium, being more or less a by-product in the manufacture of thorium salts. See Power and Shedden, on the Composition and Determination of Cerium Oxalate. (*J. Soc. Chem. Ind.*, xix, No. 7; also *Ph., Ztg.*, 1902, 297.)

Cerium oxalate was officially described as "a fine white or slightly pink powder, without odor or taste; permanent in the air. It is insoluble in water, alcohol, ether, and in solutions of potassium or sodium hydroxide; insoluble in cold, diluted sulphuric or hydrochloric acid, but dissolved by these acids when heated. When heated to redness it is decomposed, leaving not less than 47 per cent. of a reddish-brown residue. Boil Cerium Oxalate with potassium hydroxide T.S.; an insoluble precipitate of white hydroxides is produced. Filter and supersaturate the filtrate with acetic acid; the addition of calcium chloride T.S. produces a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. From a solution of Cerium Oxalate in diluted hydrochloric or sulphuric acid, potassium hydroxide T.S., added in slight excess, precipitates white hydroxides, which do not redissolve in a larger excess of the reagent, but gradually turn yellow in contact with air. Ammonium carbonate T.S. added in slight excess to a similar acid solution produces a white precipitate of the mixed carbonates of cerium and associated elements, which is somewhat soluble in a larger excess of the reagent. Dissolve 0.1 Gm. of Cerium Oxalate in 1 mil of sulphuric acid and add 2 mils of potassium sulphate T.S.; small, colorless crystals of double sulphates of potassium and the rare-earth elements in the mixture are deposited after some time. No effervescence occurs when Cerium Oxalate is dissolved in diluted hydrochloric acid (*carbonates*). A solution of Cerium Oxalate (1 in 50) in diluted hydrochloric acid does not respond to the Test for heavy metals (see Part III, Test No. 3). A solution of Cerium Oxalate (1 in 25) in hot dilute sulphuric acid (1 in 3) meets the requirements of the Test for arsenic (see Part III, Test No. 1). Boil 0.3 Gm. of Cerium Oxalate with 15 mils of potassium hydroxide T.S. and filter. No precipitate is produced in 5 mils of the filtrate by boiling with an excess of ammonium chloride T.S. (*aluminum*) or in another 5 mil portion of the filtrate by the addition of sodium sulphide T.S. (*zinc*)." *U. S. IX.*

Bachem (*A. I. P. T.*, xvii, p. 363) has shown that cerium, didymium and lanthanum are all practically non-toxic although some of their salts possess antiseptic virtues. The commercial cerium oxalate being almost insoluble is not absorbed when given by the mouth and escapes wholly through the feces. It was originally brought forward by Sir James Y. Simpson as a remedy for the *vomiting of pregnancy* and has been used extensively in this affection and also in various other gastric disturbances attended with vomiting. Baehr and Wessler (*A. in M.*, 1909) have shown, however, that it has no effect in vomiting which is of central origin. Its value as an antemetic is probably precisely parallel to that of the insoluble salts of bismuth; when used in large quantities it forms a protective coating over the mucous membrane of the stomach.

Dose, one to ten grains (0.065–0.65 Gm.) three or more times a day.

Cetraria. *U. S.* 1890. *Iceland Moss. Iceland Lichen.*—Under this name the U. S. P. formerly recognized the dried plant of *Cetraria islandica* Acharius (*Lichen islandicus* L.) This plant, although known as Iceland moss, is not a moss, but a lichen which grows in most northern latitudes and on elevated mountains further south, including the Northern United States.

The dried plant is of diversified color, grayish white, brown, and red, in different parts, with less of the green tint than in the recent state. It was officially characterized as follows: "From 5 to 10 Cm. long, foliaceous, irregularly branched into fringed and channelled lobes, brownish above, whitish beneath, and marked with small, depressed spots; brittle and inodorous; when softened in water, cartilaginous, and having a slight odor; its taste is mucilaginous and bitter." *U. S.*, 1890. Macerated in water, it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence without viscidity. After some time the dissolved matter separates, and when dried forms semi-transparent masses, insoluble in cold water, alcohol, or ether, but soluble in boiling water, and in solution forming a blue compound with iodine. *Lichenin*, or *lichen starch*, $C_{12}H_{20}O_{10}$, resembles starch in its general characters, but differs from it in some respects. Lichenin has been found to consist of two distinct proximate principles, for one of which the name lichenin may be retained, while the other has been called *isolichenin* or *dextrolichenin* or *lichenoid*. According to Th. Berg (*Thèse de Dorpat*, 1872), *cetraria* yields 35.15 per cent. of total lichen-starch. Lichenin is insoluble in cold water, but swells up and easily dissolves in hot water. It is insoluble in alcohol and in ether. It is only tinged by iodine. Isolichenin is, on the contrary, colored blue by that reagent. It is, in part, dissolved in cold water, and the undissolved part is equally colored blue by iodine. It is, like lichenin, insoluble in alcohol and ether. Both substances are hydrolizable with mineral acids, yielding dextrose. For a further account, see *J. P. C.*, 1873.

The name *cetrarin* has been conferred on the bitter principle. Herberger's process for extracting it may be found in the 18th ed., U. S. D. By it one pound of moss yielded to Herberger 133 grains of cetrarin. Schnedermann and Knop have ascertained that cetrarin consists of three distinct substances: (1) *cetraric acid*, $C_{18}H_{16}O_8$, which is the true bitter principle, crystallizable, and intensely bitter; (2) a substance resembling the fatty acids, called *lichen-stearic acid*, $C_{14}H_{34}O_3$, the crystals of which melt at 120° C. and, (3) a green coloring substance, which they name *thallochlor*. These principles are obtained perfectly pure with great difficulty. (*Ann. Ch. Ph.*, lv, 144.) Hilger and Buchner (*Ber. d. Chem. Ges.*, 1890, p. 461) gives to lichen-stearic acid the formula $C_{43}H_{76}O_{13}$, and to cetraric acid the composition $C_{30}H_{30}O_{12}$, and both are shown to be dibasic acids.

The gum and starch amounting to about 80 per cent. in the air dried moss contained in the moss render it sufficiently nutritive to serve as a food for the Lapps and Icelanders, who employ it powdered and made into bread, or boiled with milk, after having partially freed it from the bitter principle by repeated maceration in water. As suggested by Berzelius, the bitterness may be entirely extracted by macerating the powdered moss, for twenty-four hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, then decanting the liquid, and repeating the process with an equal quantity of the solution. The powder, being now dried, is perfectly sweet, and has been used to some extent in pharmacy as a substitute for acacia, although lacking in adhesiveness. (See *Proc. A. Ph. A.*, 1892, 455.) It has been recommended for emulsion, salve bases, etc., and as a vehicle for disguising the bitter taste of some laxative drugs. This plan which has been proposed of first extracting the bitterness by maceration in water or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, has been criticized, as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. A pint (473 cc.) of the decoction may be taken during the day.

Iceland Moss has been much used in chronic *catarrhs*, especially of the pulmonary mucous membrane and even in *phthisis*. It acts chiefly as a mucilaginous drink, but as Kobert has found that *cetrarin* is a stimulant to the gastro-intestinal mucous membrane and to peristalsis, cetraria probably is feebly tonic. A 20 per cent. tincture has been recommended in *doses* of twenty to thirty minims (1.2–2 cc.) by Deying and Brice-Moret as an anti-emetic (*P. J.*, Oct. 30, 1897), which is confirmed by Gigon. (*R. T.*, 1905, p. 610.)

Cetraric acid, $C_{30}H_{30}O_{12}$, the bitter principle, is soluble in solutions of alkalies and their carbonates, in hot water and slowly in cold water. It has been used in the treatment of *anemias* and *digestive disturbances*. *Dose*, one and a half to three grains (0.096–0.2 Gm.).

Decoctum Cetrariæ. U. S., 1890. *Decoction of Cetraria. Decoction of Iceland Moss.*

"Cetraria, *fifty grammes;* Water, *a sufficient quantity*, to make *one thousand cubic centimeters.* Cover the Cetraria, in a suitable vessel, with *four hundred cubic centimeters* of cold Water, express after half an hour, and throw the liquid away. Then boil the Cetraria with *one thousand cubic centimeters* of Water for half an hour, strain, and add enough cold Water, through the strainer, to make the product, when cold, measure *one thousand cubic centimeters.*" *U. S.*, 1890.

Saccharum Cetrariæ.—Cetraria 1, sugar 1, water 100. Wash the cetraria with water to remove bitterness, then boil with 100 cc. of water, strain and express lightly, and in the strained liquid dissolve the sugar and evaporate upon a water bath. When sufficiently firm remove from the bath and dry in an oven to a scale or a powder.

The *Cetraria juniperina* (probably *Cetraria vulpina*) of Europe is said to be sometimes used as a poison for wolves and foxes, while the *wolf's moss* (*Ulfmossa*) of the north of Europe contains *vulpinic acid*, $C_{19}H_{14}O_5$, which has been found by Kobert to be an active protoplasmic poison; in frogs it produces tetanus, convulsions, and paralysis of central origin; in mammals it causes dyspnea, vomiting, trembling, and a slowing of the pulse, with rise of the blood pressure due to stimulation of the respective nerve centers. After death the blood is not coagulable, and the secreting kidney cells are found covered with a crystalline or amorphous mass of a vulpinate. No difference of action exists between vulpinic acid derived from wolf's moss and that synthetically produced. From *Cetraria pinastrin* Zopf has separated *pinastrinic acid,* which seems to be very closely allied to vulpinic acid. (*Sitzungsb. der Dorpat. Naturforsch.-Gesellschaft,* 1892.)

Cetyl Alcohol. *Alcohol Cetylicum.* $C_{16}H_{33}$-OH.—*Cetylic alcohol, ethal, æthol, primary hexadecyl alcohol,* is a tasteless, odorless, waxy powder, which fuses at 49.5° C. and boils at 344° C. It is soluble in alcohol and ether. According to Grimm (*Derm. Zeit.,* 1899, vol. vi), cetyl alcohol is absorbed and obstinately retained by the epidermis, producing a peculiar velvety condition of the skin. It has been found useful in the treatment of *chapped hands,* weeping *eczema,* and *prurigo.* Mixtures of it with boric acid or the borates have been put upon the market as cosmetics under the name of *Borsyl.* Grimm especially recommends equal parts of cetyl alcohol with boric acid or one part with five of powdered talc.

Champaca.—This is the *Michelia Champaca* L. (fam. *Magnoliaceæ*), a Javan tree which is famous for the sweet odor of its blossoms. From it Merck has obtained a camphor ($C_{17}H_{30}O$) to which the name *champacol* has been applied. For a study of the volatile *oil of champaca* flowers, see *Schim. Rep.,* Oct., 1907, p. 32 and Brooks (*J. Am. C. S.,* 1911, xxxiii, p. 1763).

Cheiranthus. *Cheiranthus Cheiri* L. *Wall flower.*—The flowers yield an oil which when highly diluted has the natural pleasant odor, but when concentrated the odor is disagreeable. (*Schim. Rep.,* 1911, 95; also *A. Pharm.,* 1912, 211.) From the leaves of this cruciferous European plant Moritz Reeb (*A. E. P. P.,* 1899, xliii, p. 130) separated a glucoside which exerted a digitalis-like effect on the heart and an alkaloid resembling quinine in its physiological action. These he called, respectively, *cheiranthin* and *cheirinine.* Subsequently Wagner separated another crystalline principle, *cheiroline,* that resembled cheirinine in its effects. Schneider (*Ann. Chem.,* 1912, cccxcii, p. 1) showed that it was a methylthiocarbimido-propylsulphone $C_5H_9O_2NS_2$.

Chelidonium. *U. S.* 1890. *Chelidonium majus* L. (Fam. *Papaveraceæ.*) *Celandine. Tetterwort.* —A perennial herbaceous plant growing wild in both Europe and America, recognized readily by its pinnate leaves, small peduncled yellow flowers and yellow opaque juice. The plant was formerly official and was described as follows: "Root several-headed, branching, reddish-brown; stem about 50 Cm. long, light green, hairy; leaves about 15 Cm. long, thin, petiolate, the upper ones smaller and sessile, light green, on the lower side glaucous, lyrate-pinnatifid, the pinnæ ovate-oblong, obtuse, coarsely crenate or incised and the terminal one often three-lobed; flowers in small, long-peduncled umbels with two sepals and four yellow petals; capsule linear, two-valved and many-seeded. The fresh plant contains a saffron-colored milk-juice, and has an unpleasant odor and acrid taste." *U. S.,* 1890.

Probst, of Heidelberg, found in it a peculiar acid denominated *chelidonic acid;* also the alkaloids chelerythrine, chelidonine and homochelidonine. For description of these see Sanguinaria Part I. There is present also a neutral crystallizable, bitter principle, which from its yellow color he calls *cheliodoxanthin.* Schlotterbeck (*A. J. P.,* 1902) has shown, however, that this is berberine. For an elaborate investigation of chelidonine, see a paper by Schlotterbeck and Knapp in *Proc. A. Ph. A.,* 1905, 217. For color tests for chelidonine, see *Proc. A. Ph. A.,* 1895, 922.

Chelidonine phosphate, chelidonine sulphate, chelidonine tannate, and *chelidonine muriate* have been used medicinally.

Under the name of *Panchelidon* there has been placed upon the market a preparation said to contain all the alkaloids of Chelidonium (see *Ph. Ztg.,* 1915, 539). Hanzlik (*J. A. M. A.,* 1920, lxxv, 1324) has suggested its use in *asthma* and *spasmodic colic.* Ribbing and Rumpf have used chelidonine clinically in *gastralgias* in *doses* of one and one-half to three grains (0.1–0.2 Gm.), but Peronin used from one-twentieth to one-third of a grain (0.003–0.02 Gm.).

Celandine is an irritant purgative to which toxic properties have been ascribed with doubtful correctness; in the fatal case of poisoning reported in the *Zeitsch. f. Medizinalbeamte,* 1898, it was not the cause of death. The irritant juice has long been used locally upon *corns, warts, eczema,* and other diseases of the skin, and even in *cancer.*

The *dose* of the dried root or herb is from thirty grains to a drachm (2.0–3.9 Gm.), that of the fresh root one or two drachms (3.9–7.7 Gm.), and the same quantity may be given in infusion. The *dose* of the aqueous *extract* is from five to ten grains (0.32–0.65 Gm.), of the expressed juice from ten to twenty minims (0.6–1.3 cc.), to be gradually increased.

Chelone. *Chelone glabra* L. *Snake-head. Turtle-head. Balmony. Shellflower. Chelone,* Fr. G.—The leaves of this common indigenous, perennial, herbaceous plant, of the fam. *Scrophulariaceæ,* have a bitter taste, and are said to be tonic and aperient, with a supposed peculiar action on the liver. The decoction (two ounces of the fresh herb to the pint) may be given in the *dose* of one or two fluidounces (30–60 cc.). *Chelonin,* an eclectic medicine prepared from *chelone,* is a brown, bitter powder administered as a tonic laxative in one and two grain *doses* (0.06–0.12 Gm.).

Chemical Food. *Compound Syrup of Phosphate of Iron.*—Under the name of *Chemical Food* several of the older writers have given complex formulæ for syrup containing combined phosphates of calcium, potassium, sodium and iron. Any virtue which resides in these preparations is represented by the compound syrup of the phosphate of the N.F. (See Part III). For Parrish's formula for similar syrup see *U. S. D.,* 20th edition, page 1315. *Compound Syrup of the Phosphates* (see Part III).

Chenopodium. *Chenopodium. American Wormseed.*—The fruit of *C. Ambrosioides* var. *anthelminticum* (L.) Gray (Fam. *Chenopodiaceæ*). This species of *Chenopodium,* known commonly by the names of *wormseed* and *Mexican Tea,* grows in almost all parts of the Eastern United States. By some it is regarded as a distinct species (*C. anthelminticum* L.), by others as only a variety. It is largely cultivated in Maryland (see *Ph. Era.,* 1921, liv, 23). The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odor, which it retains when dry. All parts of the plant are occasionally employed, but the fruit alone was official in the U. S. P., 1890. This should be collected in October.

Wormseed is a utricle, a type of fruit which consists of an achene with a bladdery calyx investment. It is about 2 mm. in diameter, with a membranous pericarp, irregularly spherical, very light, of a dull greenish-yellow or brownish color, a bitterish, somewhat aromatic, pungent taste, and possessed in a high degree of the peculiar odor of the plant. These fruits, when deprived, by rubbing them in the hand, of the membranous calyx covering which invests the achene, exhibit the shining, blackish surface of the obtusely-edged achene. They abound in a volatile oil, upon which their sensible properties and medicinal virtues depend and which is obtained by distillation. (See *Oleum Chenopodii*, Part I.) The same oil impregnates to a greater or less extent the whole plant.

Of the activity of the wormseed as an anthelmintic there can be no question, but it has been entirely displaced by the official oil. The *dose* of the crude drug is from twenty to forty grains (1.3–2.6 Gm.). The seeds of *Chenopodium quinoa* form one of the staple foods of New Granada, Chili and Peru, and were used by Germany to some extent during the war. The protein content is about 20 per cent. and the starch content about 60 per cent. and 5 per cent. of fat is present also.

China Green.—This dye is asserted to have a specific antiseptic action on the *Bacillus coli* and to be useful as a means of distinguishing between that organism and the *B. typhosus.* For method of use, see Werbitzki, *Arch. f. Hyg.*, 1909, p. 191.

China Morada.—Under this name there appear to be used in Bolivia several barks. One of these has been ascertained by Arati and Canzoneri (*L'Orosi*, Feb., 1889) to be the product of a rubiaceous tree, *Pogonopus tubulosus* (Rich.) K. Sch., and to contain an alkaloid *moradeine* besides a fluorescent substance, *moradin*, allied to scolopetin. (See *P. J.*, xix.)

Chinaphenine. $CO\begin{cases}NH.C_6H_4OC_2H_5\\OC_{20}H_{23}N_2O\end{cases}$. *Quinine Carbophenetidide. Phenetidin Quinine Carbonate.*—*Chinaphenine* occurs as a white, tasteless powder, slightly soluble in water, easily in alcohol, ether, and chloroform and benzene, forming salts which are soluble in water. Chinaphenine has been recommended by von Noorden as a mild antipyretic, as an analgesic in *diabetic* and other forms of *neuralgias;* also in *whooping cough.* The analgesic *dose* is twenty to thirty grains (1.3–2.0 Gm.) given in two portions. (*Ther. Geg.*, Jan., 1903.)

Chinaphthol. *Quinaphthol. Quinine-β-naphthol-α-mono-sulphonate.* $C_{20}H_{24}N_2O_2(C_{10}H_6OHSO_3H)_2$.—This substance is a yellow, crystalline powder fusing at 185° C., of a bitter taste, insoluble in cold water, moderately soluble in hot water and alcohol; it has been proposed by E. Riegler (*W. M. Bl.*, xix, 1896) as an antipyretic and intestinal antiseptic. He states that it is decomposed by the alkalies of the intestinal juices into its constituents—namely, quinine and β-naphthol-sulphuric acid—and that he has used it up to forty-five grains (3 Gm.) a day with satisfaction in acute *rheumatism* as well as in *typhoid fever.* It contains about 42 per cent. of quinine.

Chineonal.—This is *quinine diethyl-barbiturate* and represents approximately 63.8 per cent. of quinine and 36.2 per cent. of barbital. It occurs as colorless bitter crystals, sparingly soluble in water, readily so in alcohol. The idea of combining the properties of quinine and diethyl-barbituric acid does not appear to us to be an extraordinarily happy one. Fraenkel and Hauptmann, however (*Med. Klin.*, 1912, p. 1871), believe that the drug is of special value in *whooping cough.* It has also been used as a general nerve sedative. The *dose* is five to ten grains (0.32–0.65 Gm.), preferably in the form of tablets.

Chinoidinum. *U. S.* 1880. *Chinoidine. Quinoidine. Chinoidin. Quinoidin. Precipitated Extract of Bark. Amorphous Quinine. Quinine brute ou amorphe,* Fr.—The term chinoidine was first applied to all of the amorphous alkaloids existing naturally in cinchona bark, but it is now used to define a complex body consisting largely of alkaloidal products which are artificial and accidental, resulting from the application of heat. Evaporation of the mother liquor left after the crystallization of the quinine sulphate in the preparation of that salt, yields a dark colored substance having the appearance of an extract. Sertürner supposed that he had discovered a new alkaloidal principle in this product. Later, by the conjoint labors of the chemists, Winckler, Liebig, and Pasteur, it was proved that ordinary quinoidine consisted of two alkaloids, derivatives from quinine and cinchonine, with which they are respectively isomeric, though differing in being uncrystallizable, and named, in view of their origin, *quinicine* and *cinchonicine.* These alkaloids are decomposition products, caused by the action of heat, from quinine and cinchonine respectively. They differ from their natural alkaloids in being dextrorotatory. The pure amorphous quinine of Liebig was the former of these alkaloids. (*A. J. P.*, xviii, 181.)

The U. S. P. of 1880 described chinoidine as "a brownish-black or almost black solid, breaking, when cold, with a resinous, shining fracture, becoming plastic when warmed; odorless, having a bitter taste and an alkaline reaction. Almost insoluble in water, freely soluble in alcohol, chloroform, and diluted acids; partially soluble in ether and in benzol. The solutions have a very bitter taste. If Chinoidin be triturated with boiling water, the liquid, after filtration, should be clear and colorless, and should remain so on the addition of an alkali (abs. of alkaloidal salts). On ignition, Chinoidin should not leave more than 0.7 per cent. of ash." *U. S.*, 1880.

For formulas for various salts of chinoidine, see *N. R.*, 1882, 11, or *Proc. A. Ph. A.*, 1882, 417.

As an antiperiodic, chinoidine is inferior to the Cinchona alkaloids and more nauseating. From thirty grains to a drachm (2.0–3.9 Gm.) may be given, in divided doses, between the paroxysms of an *intermittent*, and its action closely watched.

Chinol. *Quinoline mono-hypochlorite.* $C_9H_6N.ClO$.—A white crystalline powder, odorless, having a pungent but not disagreeable taste. It is almost insoluble in cold and hot water, but quite soluble in alcohol. This substance is said to be actively antipyretic and analgesic, useful for the purposes for which antipyrin is employed. *Dose*, from three to five grains (0.2–0.32 Gm.).

Chinosol. *Quinosol. N. N. R.* 1924. $(C_9O_7ON)_2H_2SO_4$. *Normal Oxyquinolin Sulphate.*—This is a neutral compound of *oxyquinoline* from which the latter is readily liberated in a nascent condition.

It is a crystalline, yellow powder, very soluble in water, insoluble in alcohol and ether, having a feeble saffron-like odor. Its aqueous solution when very dilute produces with ferric chloride a bright green color.

Chinosol does not precipitate albumin, is affirmed to be very slightly toxic, unirritating, and possessed of an extraordinary power of penetrating tissues. It is incompatible with alkalies, and with iron and mercury compounds. In the report of the Council on Pharmacy and Chemistry of the American Medical Association (*J. A. M. A.*, 1910, liv, p. 1801), it was shown that chinosol is decidedly less efficient in its killing power on bacteria than is phenol; the 1 per cent. solution is not certainly fatal to the bacillus of typhoid fever even after ninety minutes' exposure. On the other hand, its power of restraining development is far superior to that of phenol; one part in ten thousand is sufficient to prevent development of the *Staphylococcus pyogenes* or the *Bacillus typhosus*, while I in 20,000 shows a marked inhibiting effect. Its toxicity is certainly very low; in the report of the Council on Pharmacy and Chemistry, guinea-pigs and rabbits frequently survive the administration of 3 Gm. by the mouth, or 1 Gm. hypodermically. In addition to its antiseptic action it is claimed for chinosol that while its own odor is comparatively little, it is a powerful deodorizer, and also energetic as a styptic.

Although it has been used in surgery for the disinfection of instruments and of the surgeons' hands, the use of chinosol for this purpose is not to be recommended, because of its low germicidal value. On the other hand, as an antiseptic in various conditions, as *vaginitis*, *rhinitis*, and similar *catarrhs*, there is much evidence of its value. It has also been used successfully as an intestinal disinfectant, and Lorch (*Deutsche Ärzte Zeitung*, 1908, p. 406) has even obtained favorable results in the treatment of *Asiatic cholera*.

As a local application to mucous membranes, it may be used in strengths of from 1 to 500 to 1 to 2000. Internally, it has been given in *doses* of five to fifteen grains (0.3–1. Gm.).

Chione. *Chione glabra* DC. *Palo Blanco.*—The bark of this West Indian rubiaceous plant is said to be largely used as an aphrodisiac and tonic. According to B. H. Paul and A. J. Cownley, it yields 1.5 per cent. of a pale yellow volatile oil composed largely of phenols. (*P. J.*, vol. lx.)

Chloral Ammonium. $CCl_3.CH(NH_2)OH$. *Trichloramido-ethylic Alcohol.*—This substance is said by W. B. Nesbit to act like hydrated chloral, but to be a stimulant to the circulation in *doses* of from five to twenty grains (0.32–1.3 Gm.). For method of preparation, see *T. G.*, 1888. The name *chloralamide* is correct as applied to this compound, but it is more frequently, although incorrectly, applied to the substance, Chloralformamide, which see.

Chloral Amylene Hydrate. *Amylene-chloral. Methyl Butanol Chloral. Dormiol.* $CCl_3.CHOH.O(CH_3)_2C_2H_5$.—Made by mixing 10 parts of anhydrous chloral with 6 parts of amylene hydrate. It is a colorless, oily liquid, sp. gr. 1.24, having a pungent, mint- and camphor-like odor and a cooling pungent taste. It is not miscible with cold water and is decomposed by boiling water, but is freely soluble in alcohol, ether, acetone, and the fixed oils. Its incompatibilities are the same as for chloral hydrate. While there is no doubt that dormiol is a powerful somnifacient, the experiments of Mayer (*Th. M.*, 1907, p. 250) indicate that its toxicity is practically the same as that of chloral hydrate. It is at present marketed in the form of a 50 per cent. solution, the *dose* of which is ten to thirty minims (0.6–1.8 cc.).

Chloral Carbol. *Chloral Phenol. Carbolated Chloral.*—According to Boureiz, when hydrated chloral and phenol are rubbed up in the proportion of 10 parts of the former to 14 parts of the latter, a liquid is obtained which has the sp. gr. of about 1.5 and is soluble in all proportions in water, alcohol, and ether. Applied locally it is a counterirritant and local anesthetic.

Chloral Cyanhydrate. *Chloral Hydrocyanate.* $CCl_3.CH(OH)Cn$.—This is a compound first prepared by Pinner and Bischoff, and recommended by Hermes (*Ph. Centralh.*, Aug., 1887) as a substitute for hydrocyanic acid, whose physiological action it is stated to share. *Chloral cyanhydrate* is represented by the formula $CCl_3—CH—\left\{\begin{matrix}OH\\CN\end{matrix}\right.$, and is described as a crystalline powder, consisting partly of colorless prisms and partly of rhombic tables, fusing at 61° C., easily soluble in water, alcohol, and ether. With the vapor of water it volatilizes in small quantity, and breaks up into its components, chloral and hydrocyanic acid. It contains 15.33 per cent. hydrocyanic acid. It is also decomposed by alkalies, with the formation of alkaline cyanides. Its aqueous solutions remain unaltered for a long time. Six and a half parts by weight of chloral cyanhydrate correspond with one part of anhydrous hydrocyanic acid.

Chloralformamide. *N. N. R.* 1924. *Chloralformamidum. U. S. VIII. Chloralamide. Chloralum Formamidatum.* P. G. $CCl_3.CH(OH)NH.CO$.—This compound of chloral and formamide which was formerly official is made by mixing 45 Gm. of formamide with 147 Gm. of anhydrous chloral, when combination ensues; the crystalline mass is purified by recrystallization. Chloralformamide occurs as in "colorless, lustrous crystals, without odor, and having a somewhat bitter taste. Soluble in about 18.7 parts of water, and in 1.3 parts of alcohol at 25° C. It is readily soluble in ether, glycerin, acetone, and acetic ether. When heated with water to 60° C., it is hydrolyzed, hydrated chloral and formamide being produced. When heated to from 114° to 115° C. it melts, but at a higher temperature it is decomposed. It is not affected by diluted acids, but it is decomposed on warming with alkali hydroxides, the solution becoming at first turbid, and then clear, while chloroform separates. If 0.2 Gm. be heated carefully in an open dish, it should not give off inflammable vapors, and should volatilize without leaving a weighable residue (absence of *inorganic impurities* and distinction from *chloral alcoholate* and *ethyl carbonate*). One Gm. of Chloralformamide dissolved in 10 cc. of alcohol should yield a solution which does not redden moistened blue litmus paper (absence of *formic, hydrochloric*, or *other free acids*). If 1 Gm. of Chloralformamide be dissolved in 10 cc. of alcohol, the addition of a few drops of silver nitrate T.S. should not at once produce turbidity (the absence of *decomposition products*)." *U. S. VIII.*

Chloralformamide is rapidly absorbed and after absorption gradually broken up in the system liberating chloral which exercises its characteristic narcotic effects. Apparently the formamide which is liberated at the same time antagonizes the depressant action of the chloral upon the nerve centers, for in the experiments of Wood and Cerna it was found that the action upon the circulation was feeble and the respirations more rapid than normal, which results are in accordance with those of Halasz (*W. M. W.*, 1889). On the other hand Langgaard (*Th. M.*, 1889) maintains that both of these functions are depressed. Clinically the drug is much slower in its action than chloral hydrate and has the advantage of being less irritant to the stomach. It is, however, much less certain in its action and while often of service in the milder types of *insomnia* can not be relied upon for more obstinate cases. The *dose* is from fifteen to thirty grains (1 to 2 Gm.).

Chloralimide. $CCl_3.CH—NH$.—This compound should not be confounded with chloralamide. Chloralimide is in colorless, inodorous, and tasteless long crystalline needles; melting at about 166° C.; insoluble in water; readily soluble in alcohol, in ether, in chloroform, and in oils. Concerning its physiological action we have no certain knowledge; it is asserted to be hypnotic in doses of from fifteen to sixty grains (1 to 3.9 Gm.).

Chloral Menthol. *Mentholated Chloral.*—This is obtained by triturating equal weights of hydrated chloral and menthol, and heating gently in a water bath until liquefied. It is an oily, colorless liquid, with a distinctly mint-like odor and warm taste, having a specific gravity of 1.1984. It is freely soluble in alcohol, chloroform, and petroleum benzin. (*A. J. P.*, 1886, 283.) *Chloral menthol* has been used as a counter-irritant and local anesthetic in facial and other *neuralgias*.

Chloralose. $C_8H_{11}Cl_3O_6$. *Anhydro-gluco-chloral.*—When equal parts of anhydrous chloral and glucose are heated together for an hour at the temperature at which chloral boils, two isomeric substances—*chloralose*, which is soluble, and *parachloralose*, which is insoluble—are formed. *Chloralose* occurs in small crystals having a very bitter and disagreeable but not acrid taste. It is freely soluble in alcohol and in hot water, slightly so in cold water, a little less than five grammes to the liter. Its melting point is 185° C.

Chloralose was introduced by Henriot and Richet (*C. R. S. B.*, 1893) who state that in the lower animals it is an active hypnotic differing from chloral in that it is not depressant to the circulation, has a stimulant rather than a depressant effect upon the motor centers of the brain and spinal cord and has a marked anesthetic power. This statement has been confirmed by Gautrelet (*J. P. C.*, 1918, xvii, 408).

As a practical hypnotic, the action of chloralose is very variable and is often attended by disagreeable results, ten grains frequently failing to cause sleep, although the same amount has produced complete unconsciousness with alarming symptoms. Partial general paralysis, tremors, great slowing of the pulse, and marked evidences of enfeebled heart action have not rarely followed the use of the drug, while involuntary discharges of urine, delirious intoxication, excessive vomiting, and other disagreeable symptoms have been noted. The *dose* is from five to ten grains (0.32–0.65 Gm.), given in capsules.

M. H. Rendu (*B. Hôp. Par.*, xx, 1895) has reported violent collapse, excessively rapid feeble pulse, pronounced disturbance of respiration, epileptiform convulsions, and collapse as produced by four grains (0.26 Gm.) of chloralose.

Chlorarsenol. *Solarson.*—Under this name is furnished a solution which is stated is contain 1 per cent. of *ammonium heptinchlorarsenate*.

This solution is recommended as a substitute for arsenous oxide in the treatment of *anemia, skin diseases, malaria,* etc. The advantages claimed for it are that it is much less irritant and can be given successfully by hypodermic injection and that, therefore, there is more certain absorption and benefit. It is supplied in the form of ampules, each containing 1 cc. and representing approximately 0.004 Gm. (one-fifteenth grain) of arsenous acid.

Chlorcresols.—The combinations of chlorine with the cresols are all of them active germicides.

The alcoholic solution of meta-chlorcresol has been highly recommended by Gottschalk (*D. M. W.*, 1911, p. 928) and others for the disinfection of the surgeon's hands. He used a proprietary preparation, *eusapyl*, which is an aqueous solution of chlorcresol in potassium ricinoleate. He used this solution in 1 per cent. strength in 70 per cent. alcohol. Another similar preparation is on the market under the name of *lysochlor*.

A compound of meta-chlorcresol with an alkali which is sold under the name of *grotan*, according to Schottelius, destroys all vegetative bacteria within five minutes if present in the strength of 0.5 per cent., and even the highly resistant anthrax spores are killed by a 1 per cent. solution in twenty minutes.

Chloretone. *Trichlorbutyl Alcohol. Acetone-chloroform. Chlorbutanol. N. N. R.* 1924. $CCl_3.(CH_3)_2.C.OH + \frac{1}{2}H_2O$.—It forms colorless crystals fusing at 80° to 81° C. It is soluble in approximately 125 parts of water, more readily soluble in alcohol and glycerin. It forms a mass or liquid when triturated with antipyrine, exalgine, menthol and phenol.

Chloretone, in 1894, was introduced as an anesthetic and hypnotic by J. A. Abel. When given in proper *doses* it produces in the lower animals a profound sleep with complete anesthesia without the respiration or blood pressure being seriously affected, although the period of sleep may last some hours or even days. If the dose be sufficient, however, death occurs from asphyxia. Chloretone has no influence upon the blood, very little upon blood pressure, although when brought locally in contact with the heart it acts as a depressant. The bodily temperature is distinctly lowered during anesthesia. The results of Abel in regard to the toxicity of chloretone have been challenged by E. Impens, who finds that chloretone restricts the combustion of oxygen more than 50 per cent. and that it is more dangerous than hydrated chloral.

Chloretone is a very useful anesthetic in the physiological laboratory. For this purpose it is best dissolved in olive oil and administered by intraperitoneal injection. The *dose* should be from 0.1 to 0.2 Gm. (1.5–3 gr.) per kilogramme of body weight.

Chloretone, as a hypnotic and antispasmodic, has failed to achieve the confidence of the profession, possibly because of timidity in dosage. Hutchins (*Annals of Surgery*, July, 1909) and Hobbs (*B. M. J.*, Nov., 1910) found it useful to control the convulsions of *tetanus*. They give from 45 to 60 grains (3–4 Gm.), dissolved in olive oil, per rectum in 24 hours. According to Hamilton chloretone has a phenol coefficient of 1.2. The saturated aqueous solution (containing about 0.8 per cent.) is a complete bacteriostatic and will destroy the *Bacillus typhosus* in two minutes' exposure. Rowe (*J. A. Ph. A.*, 1924, xiii, 22) finds that it has a marked relaxing effect on involuntary muscles. As a local remedy, chloretone is often of value because of its being both antiseptic and anesthetic, although its slight solubility in water interferes with its usefulness.

A dusting powder containing 1 to 2 per cent. has been found a serviceable application in painful ulcerations. Fioca (*Press. Med.*, 1917, p. 460) has reported favorable results from the use of pure chloretone, finely powdered, in painful conditions of the mucous membranes, as in the dysphagia of *laryngeal tuberculosis.* It is also of service for the relief of *gastralgia* and *vomiting;* Wynter (*Lancet*, 1907) and others have reported good results in the treatment of *sea-sickness.* A 1 per cent. solution, with menthol and camphor, in liquid petrolatum, has been used as a spray in inflamed states of the nasal mucosa.

The *dose* of chloretone for internal administration is ordinarily from five to fifteen grains (0.32–1 Gm.), but larger amounts may be given with safety.

According to Aldrich (*J. Biol. Chem.*, 1918) it may be detected in aqueous solutions by distilling with steam and then boiling the distillate in a flask provided with a reflex condenser. Needle-shaped crystals of chloretone will appear in the lower cooled end of the condenser which can be distinguished from chloral, camphor and brometone by physical and chemical tests.

Chlorine. *Chlorine gas.* Cl = 35.46.—The element chlorine is a greenish-yellow gas with an extremely irritating odor and about 2.5 times heavier than the air. It is the active ingredient in several official compounds, such as chlorinated lime and solution of chlorinated soda. In the elemental form it was the first poison gas employed during the World War. It has also recently come into popularity as a treatment for acute respiratory infections such as acute coryza. Vedder and Sawyer (*J. A. M. A.*, 1925, lxxxiv, 361) have reported over 1000 cases of *coryza, acute laryngitis, bronchitis, whooping cough* and *influenza* in which the inhalations of the gas apparently proved of much value. They used a concentration of about 0.015 milligramme per liter of air. Its real value, however, remains to be proven.

Chlorostigma. *Tasi.*—The *C. Stuckertianum* (*Asclepiadaceæ*), a South American plant, is asserted to contain an alkaloid, *chlorostigmine*, which has been used to stimulate the secretion of milk.

Chlorphenols.—By the action of chlorine upon phenol is produced a mixture of ortho- and para-chlorphenol ($C_6H_4Cl.OH.$) and by continued action trichlorphenol ($C_6H_2Cl_3.OH.$). *Orthochlorphenol* is a liquid boiling at 175° C. and solidifying at 7° C.; the *parachlorphenol* forms crystals melting at 37° C. and boiling at 217° C. Both have an unpleasant penetrating odor. *Trichlorphenol* (*omal*), which was discovered by Laurent, crystallizes in needles, which melt at 68° C. and boil at 244° C. It is easily soluble in alcohol and ether.

The introduction of one or more chlorine atoms into the phenol molecule increases very markedly the germicidal power and apparently in proportion to the number of chlorine atoms introduced. Unfortunately, however, the caustic and poisonous actions seem to be increased also. Karpow, working in the laboratory of Nencki, demonstrated that both orthochlor- and parachlorphenol escape with the urine, in combination with sulphuric acid, and probably also with glycouronic acid, the urine becoming rapidly blackish on exposure to air, and confirmed the observations of Külz (*A. G. P.*, Bd. xxx) that the urine of dogs poisoned with the chlorphenols polarizes to the left. It would appear almost certain that the chlorphenols undergo at least partial decomposition in the organism, giving origin to hydroquinone, pyrocatechin, and other educts found after poisoning with phenol. The action of these chlorophenols upon the general system is probably practically that of phenol. According to Bechold and Ehrlich (*Z. P. C.*, 1906, xlvii, p. 173), trichlorphenol in the strength of 1 part in 10,000 prevents the growth of all bacteria and is equivalent to 1 in 800 of phenol. Nencki states that a 2 per cent. solution of monochlorphenol is superior to a 5 per cent. phenol solution.

Spengler (*Arch. des Sci. Biol.*, 1895, iv) states that the parachlorphenol is especially poisonous to the tubercle bacillus and recommends its 10 per cent. solution in the treatment of *tubercular laryngitis.* In dilute solution the chlorphenols have also been used as general surgical disinfectants, but have failed to establish themselves clinically.

The *chlorsalols*, the *salicylic esters of chlorphenols*, were studied by Nencki and found to undergo decomposition in the intestines or system, the salicylic acid or its derivatives appearing in the urine. The antiseptic properties of these chlorsalols were found to be much greater than that of salol. Girard has used them in *doses* of from sixty to ninety grains (3.9–5.8 Gm.) a day in *cystitis* and *diarrhea* with excellent results. Passerini has employed them in *phthisis* and in *bronchitis* by means of an inhaling apparatus in which fifteen minims (0.9 cc.) are placed on a piece of cotton, the patient inhaling with slow and deep inhalations from five to ten minutes daily. Usually at first some pulmonic irritation, and even for a day or two temporary exacerbation, occur, but the final results were said to be remarkable.

Chlorolin is a liquid said to contain about 20 per cent. of a mixture of mono- and tri-chlorphenols. It is used as a disinfectant.

Menthorol, so-called, is a moderately thick liquid, with an agreeable taste and the odor of parachlorphenol, which is said to be a mixture of menthol and parachlorphenol. It may be used as a local remedy in a 5 to 15 per cent. solution in the treatment of *ulcerations of the throat and lungs.*

Chlorpicrin.—This compound which results from the action of nitric acid upon chloroform has been found practically useful for the destruction of insects in rooms. According to Roux (*C. D.*, 1919, xci) 750 Gm. of the gas will kill all insects in a room of 75 cubic meters within four hours.

Cholesterin. *Cholestrin. Cholesterol.* $C_{27}H_{46}O$.—This is a monatomic alcohol and occurs in wool fat, bile, and cod liver oil. When pure it is in the form of white scales, unctuous to the touch, very sparingly soluble in water but readily so in ether or chloroform. It has the property of neutralizing many hemolytic poisons, such as snake venom, saponin, etc., as has been shown by Ranson (*D. M. W.*, 1901) and confirmed by Jahnson-Blohm. (*Z. P. C.*, 1913, lxxxv, p. 59.) Because of this property it has been used in medicine in the treatment of various dyscrasias of the blood; thus it has been employed in *malarial hematuria* and other forms of *hemoglobinuria*, in *purpura*, *chlorosis*, *pernicious anemia*, and other forms of *anemia.*

Pringsheim (*Med. Klin.*, 1913, p. 254) recommends that it be administered intramuscularly, using doses of eight grains (0.5 Gm.) daily in the form of an aqueous emulsion. Reicher (*B. K. W.*, 1908) administers it by mouth dissolved in olive oil. He gives a 3 per cent. solution in tablespoonful *doses.* Under the name of *choleol* there is upon the market an oily solution which is claimed to contain the palmitin and olein esters of cholesterin. Almangea and Mendes (*Il Morgagni,* March 30, 1907) assert that *cholesterin* has the power of fixing the toxin of tetanus, and report two cases of *tetanus* which were cured by daily injections of cholesterin.

Chrome Yellow. *Chromate of Lead. Lemon Yellow. Leipsic Yellow. Paris Yellow.* $PbCrO_4$.—This is the neutral *lead chromate* prepared by precipitating a solution of lead nitrate with potassium chromate. It is of a beautiful lemon-yellow color. The *basic lead chromate* ($PbO,PbCrO_4$) possesses a red color, and is sometimes used as a pigment. *Chrome green* is either *chromium sesquioxide* or a mixture of chrome yellow and Prussian blue. The chromates are often adulterated with lead sulphate. Duviller (*J. P. C.,* Août, 1873, 114) detects this by heating one part of the suspected pigment with a mixture of from two to three parts of nitric acid, sp. gr. 1.420, one to two parts of water, and one-fourth part of alcohol. The chromate is all dissolved, but any sulphate present remains unaffected. Lead chromate has been used by bakers in place of eggs for giving a rich yellow coloring to buns, and there can be no doubt of its having produced fatal poisoning in a number of cases. This dangerous adulteration of food has not been reported for some years, but it was recently reported as being used in a coffee glazing preparation.

Chromium.—Chromium was discovered by Vauquelin in 1797. Its most common ore is *chrome iron,* consisting of ferrous oxide and chromium sesquioxide. This is not an abundant mineral, the principle source of supply being at present Asia Minor. Chromium is obtained by igniting its oxide in contact with charcoal with the aid of the electric arc; or by the more recent methods of reduction of its oxide by finely divided metallic aluminum (Goldschmidt), or by metallic silicon (Gren and Wahl). It is a brittle metal, of a grayish-white color like platinum, with some luster, and very hard, so that it scratches glass. Its sp. gr. is 6.5 to 6.8 at 15° C., atomic weight 15.7, and symbol Cr. It does not change by exposure to the air, and is with difficulty attacked by the acids. It forms with oxygen five compounds: (1) the monoxide (CrO), (2) the sesquioxide (Cr_2O_3), (3) the trioxide or chromic anhydride (CrO_3). (See *Chromii Trioxidum.*) Of the two others, one may be considered as a compound of the monoxide and sesquioxide ($CrO.Cr_2O_3$), and the other, called *perchromic oxide,* consists of two atoms of chromium and seven of oxygen (Cr_2O_7). Chromium combines with chlorine in two proportions, forming the *dichloride* and *sesquichloride.* The chief value of chromium in the arts is as the source of potassium dichromate and of pigments.

Chromium Sulphate.—This salt has been used by Kolipinski (*M. A.,* 1908) in a remarkably wide range of disorders. Thus, he has employed it with asserted success in *prostatic hypertrophy,* in *fibroid tumors* of the *uterus,* in *nervous vomiting,* for the relief of *menopausal symptoms,* but he especially recommends it in the treatment of *locomotor ataxia* and *exophthalmic goiter.* His results do not appear to have been confirmed.

Chrysarobin Oxidized. *Chrysarobini Oxydatum.*—A brownish-black powder, obtained by boiling chrysarobin in water with sodium peroxide; its 5 to 10 per cent. ointment has been highly recommended by Unna in the treatment of facial, genital, and other forms of *eczema* for which chrysarobin is too irritating. It has no influence in dry eruptions.

Cichorium. *Cichorium Intybus* L. *Chicory. Succory. Blue Sailors.*—A perennial herbaceous composite plant, indigenous to Europe, but naturalized in the Northern United States and Canada, where it grows in fields, and in roads along the fences. The whole plant has a bitter taste, without acrimony or any very peculiar flavor. The taste is strongest in the root and weakest in the flowers. The leaves, when young and tender, are eaten as salad. Chicory is a feeble, non-irritating tonic. Nietzki (*A. Pharm.,* 1876) found in the blossoms a glucoside to which the formula $C_{32}H_{34}O_{19}$ has been assigned.

The root is much used as a substitute for, or adulterant of, coffee. In preparing it, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (*Ph. Cb.,* 1850, 688.) For methods of detection in ground coffee, see *P. J.,* 1867, 141; also Allen (*Com. Org. Anal.,* 2d ed., vol. iii, part 2, 540), and J. R. Leebody (*Chem. News,* 1874, 243); see also paper by LaWall and Forman (*A. J. P.,* 1913, 535). Chicory root itself is sometimes adulterated with beet root. The latter may be detected according to Collin (*Ann. Falsif.,* 1917) by numerous oral cells filled with calcium oxalate.

The garden *endive* is a variety of *Cichorium, Endivia* L.

Cicuta. *Cicuta virosa* L. *Water Hemlock. Cowbane. Ciguë vireuse,* Fr. *Wasserschierling,* G.—A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous to most animals, though said to be eaten with impunity by goats and sheep. A number of the species of *Cicuta* are intensely poisonous; indeed, the statement is made that *C. maculata* L. is the most poisonous plant native in the United States. The *C. vagans* (*Oregon water hemlock*), *C. occidentalis* Dougl. and *C. bulbifera* L., all of which are found in various parts of North America, are actively poisonous, as is also the European species *C. virosa.* From the last named, Van Ankum (*J. P. C.,* 1868) obtained a resinous body which was intensely poisonous, resembling picrotoxin in its physiological action, and to which he gave the name of *cicutoxin.* This has since been shown by Jacobson (*J. Am. Chem. Soc.,* 1915, xxxvii, 1916) to occur in the *C. maculata, C. bulbifera* and *C. occidentalis.* It is a yellowish, viscid liquid which, however, can be obtained as an amorphous solid by dropping a concentrated alcoholic solution in the cold benzin. It has weak alcoholic properties and is very sensitive to heat being decomposed by a temperature of 100° C. Jacobson assigns to it the formula $C_{19}H_{26}O_3$. Böhm (*A. E. P. P.,* v, 281) obtained from the dry root about 3.5 per cent., the fresh 0.2 per cent. of cicutoxin. The presence of a volatile alkaloid resembling coniine, and termed *cicutine,* has been observed by Wittstein and Buignet. According to Jacobson, cicutoxin is fatal to lower animals in doses of 50 mgm. per kilo.

Cicuta maculata L., *American water hemlock, Musquash root, Beaver poison, Spotted cowbane.*

This grows in meadows and on the borders of streams throughout the United States, and is closely analogous, in botanical character and in effects, to the European species. In several instances children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having an odor and taste not unlike those of parsnip. For microscopic examination of plant, see *A. J. P.*, July, 1891, and *Merck's Report*, 1909, p. 35. Cicuta has been highly lauded as a specific in nervous and sick *headache* (*Proc. A. Ph. A.*, 1858, 253), but is rarely if ever used. J. E. Young found in the seeds an alkaloid supposed to be identical with coniine. (*A. J. P.*, xxvii, 294, confirmed by R. Glenk, *A. J. P.*, 1891, 328.)

Egdhal (*A. I. M.*, 1911, vii, p. 348) has collected the history of 46 cases of poisoning by cicuta, of which twenty-one were fatal. Nausea, vomiting, and convulsions occurred in practically all the cases. In most of them there was also bloody froth at the mouth and in many dilated pupils and unconsciousness. In his own case there was cyanosis apparently from interference with the respiration by the convulsions.

In cicuta poisoning there is generally violent vomiting, followed by vertigo, cold clammy skin, slow, feeble pulse, general convulsions and later paralysis, unconsciousness and dilated pupils. Tannic acid has been suggested as an antidote, but its efficiency has not been proved. The treatment should be evacuation of the stomach, stimulants to combat the collapse, and the cautious use of morphine to control the vomiting and convulsions.

Cignolin. 1–8—*Dioxy-Anthranol.*—This is a yellow powder soluble in fats, alcohol, acetone, etc. It is asserted to have a similar effect to chrysarobin and to be a valuable local remedy in *psoriasis.* (See *Ph. Era.*, 1916, xlix, 193).

Cinchonidine Salicylate. *Cinchonidinæ Salicylas.* $C_{19}H_{22}ON_2.C_7H_6O_3$.—This salt occurs in needles soluble at 18° C. in 766 parts of water. It is capable of producing physiologically the action of the quinine salts, but as an antiperiodic is inferior to other salts of that alkaloid. It has been recommended and considerably used as a specific in *chronic* and *subacute rheumatism*, in *doses* of from fifteen to twenty grains (1–1.3 Gm.) a day, best given in pill or capsule.

Cinchophen Compounds.—A number of compounds of phenyl-cinchoninic acid have been introduced under various trade names as remedies in *rheumatism* and *gout.* The action of these is essentially similar to that of the official cinchophen (see Part 1) although various advantages of lower toxicity and lack of irritant action upon the stomach is claimed for them.

Acitrin is the ethyl ester of phenyl-cinchoninic acid $C_9H_4N.C_6H_5COOC_2H_5$. It occurs as a pale yellow crystalline powder without odor or taste, very slightly soluble in water but soluble in alcohol or ether. The *dose* is eight to fifteen grains (0.5–1.0 Gm.).

Chloroxyl (*Cinchophen Hydrochloride*—$C_{16}H_{11}O_2N.HCl$) is a yellow crystalline powder with an astringent, bitterish taste, insoluble in water, sparingly soluble in alcohol. The *dose* is eight to fifteen grains (0.5–1.0 Gm.).

Paratophan. Methyl-atophan. Homophan $CH_3.C_9H_4N.C_6H_5COOH$.—This is the methyl ester of phenyl-cinchoninic acid. It is a yellow crystalline powder insoluble in water but dissolved by alkalies, also soluble in alcohol or ether. The *dose* is eight to fifteen grains (0.5–1.0 Gm.).

Iriphen is *strontium-alpha-phenylcinchoninate.* It occurs as a yellowish-white crystalline powder and is employed in *doses* of from eight to fifteen grains (0.5–1.0 Gm.).

Neocinchophen. N. N. R. 1924. *Novatophan,* or *Neoquinophan* $CH_3.C_9H_4N.C_6H_5COOC_2H_5$ is the ethyl ester of paratophan. It is a yellowish, odorless and tasteless powder, almost insoluble in water but soluble in alkaline solutions and in alcohol. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Oxyl-iodide—$C_{16}H_{11}O_2N.HI$.—This is said to be the hydriodide of cinchophen and to represent 67 per cent. of phenylcinchoninic acid and 33 per cent. of iodine. Its effects would seem to be due more to the iodine than to the cinchophen portion. It is recommended in *doses* of three to nine grains (0.2–0.6 Gm.).

Isatophan. Methophan. Methoxy-Atophan. Methoxy-phenyl-cinchoninic acid. $C_9H_5N.C_6H_5COOCH_3O$. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Tolysin.—This is an ethyl ester of para-methyl phenyl cinchoninic acid and therefore isomeric with neocinchophen. Barbour, Lozinsky and Clements (*A. J. M. S.*, 1923, clxv, p. 708) find that this compound differs in its effects from cinchophen in that it is so slowly absorbed from the intestines that it is very difficult to give large enough doses to cause toxic manifestations. They find it is a useful drug in *rheumatic fever* and other forms of *arthritis.* They recommend *doses* of fifteen to thirty grains (1–2 Gm.).

Cineraria Maritima L.—This composite plant, known popularly as *Dusty Miller,* is a native of the West Indies, and has been introduced as a house plant into this country. There is upon the market a proprietary preparation which professes to be the expressed juice of this plant, and is recommended in diseases of the eye, especially as an absorbent of *cataracts.* We do not know, however, of any sufficient scientific justification for a belief in this improbable property.

Cinnamic Acid. *Acidum Cinnamicum.* $C_6H_5-CH=CH.COOH$.—This acid occurs naturally in Peru and Tolu balsams and in Styrax, and is made synthetically by the reaction of acetyl chloride upon benzaldehyde, or by the action of a mixture of acetic anhydride and fused sodium acetate upon benzaldehyde. It forms colorless, lustrous plates, melting at 133° C., and is insoluble in cold water, but quite soluble in boiling water and in alcohol. Under the name of *hetol, sodium cinnamate* has been used to a considerable extent in the treatment of *tuberculosis.* For a volumetric method of assay of sodium cinnamate, see *P. J.*, 1910, 365. A. Landerer (*M. M. W.*, xxxv, Nos. 40, 41), put forward most remarkable claims for it; but W. J. Robinson (*M. A.*, 1902), after careful review of all the evidence, reached the conclusion that sodium cinnamate is not a direct curative agent in tuberculosis and is of no more value symptomatically than is creosote. Sodium cinnamate may be given by the mouth in *doses* of from two to three grains (0.13–0.2 Gm.). The initial intravenous *dose* of the intravenous treatment recommended by Landerer, should not exceed one-fiftieth of a grain (0.0013 Gm.); the injection may be made every third day and the amount increased until one-third of a grain (0.021 Gm.) has been reached. A 10 per cent. solution in glycerin affords an excellent method of administration. Sodium cinnamate has also been recommended for the treatment of *keratitis*. Pflüger (*Klin. Monatsbl. für Augenheilkunde*, 1901) instils into the eye a 1 per cent. solution to which is added 1 per cent. of cocaine.

Citarin. *Citromin. Goutine. Sodium Anhydromethylene-citrate.*  $(NaO.COCH_2)_2.CO\left\langle\begin{matrix}CH_2\\CO\end{matrix}\right\rangle O$.—This is a white, granular, hygroscopic powder possessing a slightly acidulous taste. It is soluble in less than 2 parts of water. It readily liberates formaldehyde from its solutions, especially in the presence of alkalies. It is asserted to be a useful remedy in cases of *uric acid gravel*, and in *gout* and *chronic rheumatism*, in *doses* of thirty to forty-five grains (2–3 Gm.) four times a day.

Citrophen. *Paraphenetidin Citrate.* $C_3H_4(OH)(CONH.C_6H_4OC_2H_5)_3. + 3H_2O$.—This compound of citric acid and *p*-phenetidin is a white, crystalline powder, soluble in forty parts of water, with a faint acid taste; its melting point is 181° C. and its ready solubility in water adapts it for hypodermic use. It is used as an antipyretic, also in *migraine* and *neuralgia*. *Dose*, ten to fifteen grains (0.65–1.0 Gm.).

An identifying test for citrophen is the production of a beautiful violet color when its solution is mixed with a solution of potassium dichromate. This reaction is also given by pyramidon which, however, does not give the reaction for the phenetidin group.

Civet. *Zibethum. Civette*, Fr. *Zibeth*, G.—This is an odorous substance, obtained from two animals of the genus *Viverra;* the *V. Civetta* or *civet cat* of Africa, and the *V. Zibetha*, which inhabits the East Indies. It is secreted in a cavity opening between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odor, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable fatty taste. When heated it becomes quite fluid and at a higher temperature takes fire and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol, but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. Sack (*Ap. Ztg.*, 1915, 423) has separated from civet a ketone which he calls *zibethon* which, even in solutions as low as 1 in 1000, shows a fine musk-like odor. E. Charabot and A. Hébert give the following tests for *civet* of normal quality: When dissolved in a mixture of alcohol and ether less than 6 per cent. residue should remain. The saponification number of civet should exceed 100, and the fatty acids which are separated from the saponified civet after acidulation with sulphuric acid should exceed 50 per cent. (*Bull. Soc. Chim.*, 1910, iv, 7, 687.) In medicine it was formerly employed in lieu of castor and musk; it is now used exclusively as a perfume. For analyses of commercial samples, see *P. J.*, 1897, 101.

Clematis. *Clematis recta* L. (*C. erecta* L.) (Fam. *Ranunculaceæ.*) *Upright Virgin's Bower. Waldrebe*, G.—A perennial European plant. The leaves and flowers have an acrid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing, and applied to the skin they produce inflammation and vesication; hence their old name of *Flammula Jovis.* The acridity is greatly diminished by drying. Störck found this clematis to be diuretic and diaphoretic, in *doses* of from one to two grains (0.065–0.13 Gm.) of the extract a day, or from thirty to forty grains (2–2.6 Gm.) of the leaves given in infusion three times a day, and to be useful, locally and internally, in *syphilitic, cancerous*, and other *foul ulcers.*

Other species of *clematis* have the same acrid properties; among these *C. flammula* L., or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. vitalba* L., or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. virginiana* L., or *common virgin's bower*, *C. viorna* L., or *leather flower*, and *C. crispa* L. have been used as substitutes for *C. recta* L. All these are climbing plants. Rochebrune (*Toxicol. Africaine.* i) affirms that he has found in *C. flammula* L. an alkaloid, *clematine*, two milligrammes of which will produce in the guinea-pig copious and frequent urination, general tremors, great disturbance of respiration, feebleness and intermittency of the heart beat, followed in seven minutes by convulsions ending in coma and death.

From the bruised roots and stems of *C. vitalba* L., boiled for a few moments in water to diminish their acridity, and then digested in sweet oil for a little while, is made a preparation used locally in Europe for the *itch.* Gaube has found in this species an alkaloid. (*J. P. C.*, 1869.)

Clemens's Solution.—*Arsenic bromide* was introduced as a remedy in diabetes by Clemens. This preparation is recognized in the N. F. IV under the name *Liquor Arsenicalis Clemens* (see Part III). It was formerly called *Liquor Potassii Arsenitis et Bromidi* and contains one gramme of arsenic trioxide to the liter (in the form of a complex mixture with bromine and potassium). According to Clemens, the commencing dose of such a solution is one minim three times a day, increased gradually until the equivalent of one-fifth of a grain of the salt is daily exhibited. The clinical reports in regard to this remedy in *diabetes* seem to indicate that along with a restricted diet it is occasionally of distinct service, but in the majority of instances fails to accomplish good.

Clove Bark. *Cortex Caryophyllatus. Cassia Caryophyllata.*—The bark of *Dicypellium caryophyllatum* Nees. (Fam. *Lauraceæ*), a tree indigenous to Brazil but also growing in the West Indies. It is usually in large compound quills, up to 4 cm. thick and 60 cm. in length, composed of numerous separate pieces 1 to 2 mm. thick, rolled around one another and having a chestnut brown color, being more or less flaky on the outer surface and finely striate on the inner surface, with a short fracture showing a whitish line near the outer margin, a pungent taste, and an odor similar to that of cloves (see *A. J. P.*, vol. xv).

Cnidium Officinale.—K. Sakei (*Chem. Abst.*, 1917, xi, 2386) states that native practitioners of China, Japan and Korea use the roots of this plant extensively for various nervous diseases, especially those of the head and brain, and for some female disorders. The chief ingredient of extracts of this drug is a volatile oil—*oil of cnidium*, which is present to the extent of about

0.82 per cent. He finds the volatile oil is a stimulant to the vaso-motor system and to the spinal cord.

Coal Tar Colors.—Many colors used in dyeing and in coloring food-stuffs, beverages and medicines are synthesized from one or the other of the commercially valuable fractions of coal tar. Many of these were formerly known as *aniline colors*, because the earlier colors of coal tar origin came from the fraction known as *aniline*. As many of them are now commercially prepared from other fractions of coal tar, the term *coal tar colors* seems more appropriate. A large number of the coal tar dyes are active anti-bacterial agents. Davis found that 61 out of 204 dyes studied by him had antiseptic properties. Kligler (*J. Ex. M.*, 1918, xxvii, p. 463) has made an elaborate study of the relation between chemical structure and germicidal effect, especially of the triphenylmethane compounds. Most of these which have attained any therapeutic importance, are described under their appropriate titles. (See *Fuchsine, Methyl Violet, Scarlet Red*, etc.)

The use of coal tar colors for artificially imitating the natural color of any food-stuffs is now largely prohibited by law, with the exception of such instances where the color is used principally for æsthetic reasons, as in confectionery, or where proper notice is given to the consumer by plainly printing on the label of the package the words "Artificially colored." Even then such colors are sometimes prohibited, as in the legislation in Pennsylvania concerning fruit syrups (Act of 1905) where all coal tar colors are specifically prohibited in the act.

The feeling against the use of coal tar colors as such, which still largely obtains among the uneducated and less well informed, is undoubtedly due to the indiscriminate use of them in the early days and the fact that many of them were not freed from poisonous mineral constituents like arsenic or mercury, compounds of which were often used in their manufacture. Many of the coal tar colors in former use are now known to be harmful, such as *victora yellow* (*dinitrocresol*). A list of permissible colors has, therefore, been prepared by the U. S. Department of Agriculture, which may be used under such circumstances as permit the use of a harmless color and when not otherwise prohibited. This list has been adopted by a number of the States having food laws in harmony with the National legislation on this subject.

Cobalt. (Co = 58.56.)—This not very abundant metal is usually found associated with arsenic, and is rarely used in its pure condition in medicine or pharmacy. It occurs as *smaltine* or *tin-white cobalt, cobalt glance*, or *sulpharsenide; cobalt bloom, erythrine*, or *arsenate*; *earthy cobalt* or *wad*, a mixture of cobaltous oxide and black manganese oxide, and *spiess cobalt*, $(Co,Ni,Fe)As_2$. It is found chiefly in Bohemia, Pretoria, Sweden, Ontario and Colorado and in smaller amounts in Cornwall and Silesia. Almost the whole of the world's commercial supply now comes from Cobalt City, in the Lake Tamiskaming district, Ontario, Canada. Here the arsenides of cobalt and nickel are associated with silver and constitute a valuable by-product of the silver mining of that district.

Spiess cobalt is frequently employed as the source of cobalt salts, and the substance called in commerce *zaffre* is an impure cobalt arsenate, made by simply roasting the crude cobalt ores or calcining them, with access of air, and is used to give a blue color to glass, enamels, and pottery glaze. The native ore is frequently found in commerce under the name of *flystone*, and is used for poisoning flies, by roughly grinding it and putting a small quantity in a saucer with sweetened water. *Smalt* is the common name used for glass colored by fusing with cobalt oxide, producing a blue pigment, for coloring glass, etc. The soluble salts of cobalt, particularly the *chloride* and *sulphocyanate*, have been used to impregnate paper,* etc., giving it ordinarily a pink tint, indicative of the presence of moisture, while on elevation of temperature and drying the color changes to blue. Advantage has been taken of this fact to produce the so-called *barometer paper*.

A cobalt oxide, prepared by precipitating the chloride with potassium hydroxide, has been employed in *rheumatism*. It is emetic in the *dose* of 10 to 20 grains (0.65–1.3 Gm.). The salts of the metal are irritant poisons. The statement that the cobalt salts and hydrocyanic acid will form in the animal system a potassium or sodium-cobalt-cyanide and are antagonistic poisons and may be used as antidotes one for the other, is probably not correct. (See Hübner, *A. I. P.*, vol. ix.)

Cobalt Blue.—This beautiful pigment is a compound of cobalt oxide and aluminum oxide, obtained by precipitating the mixed solutions of a salt of aluminum and one of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (Berzelius.) The *cobalt blue* of Thénard is made by heating together the hydrated cobalt sulphosphate and aluminum hydroxide. It is used in painting.

Cobweb. *Spiders' Web. Tela Arachneæ.*—Spiders' webs were formerly much used in *headache, hectic fever, asthmas, hysteria*, and *nervous irritation*, but probably acted solely through the imagination. *Dose*, from ten to twenty grains (0.65–1.3 Gm.) *pro re nata*. Spider's web was formerly used as a styptic, especially after extraction of teeth, the cavity being stuffed full of the web.

Coca. *Cocæ Folia U. S. P. VIII. Br.* 1898. *Coca Leaves. Cuca. Feuilles de Coca*, Fr. *Cocablätter*, G. *Coca del Peru, Ipadu*, Sp.—"The dried leaves of *Erythroxylon Coca* Lamarck (Fam. *Erythroxylaceæ*), known commercially as Huanuco Coca, or of *E. Truxillense* Rusby, known commercially as Truxillo Coca, yielding when assayed by the process given below, not less than 0.5 per cent. of the ether-soluble alkaloids of Coca." *U. S. VIII.* "The dried leaves of *Erythroxylum Coca*, Lam., and its varieties." *Br.*, 1898.

The *coca* plants are shrubs or small trees, some of the species reaching the height of fifteen or twenty feet. It is conjectured that the original habitat was in the Peruvian mountains, from 7° South to 10° North, but either spontaneously or through cultivation the coca shrubs have spread until they are found in the whole Eastern curve of the Andes, from the Straits of Magellan to the borders of the Caribbean Sea, growing on the moist sides of the mountains at the elevation of 1500 to 6000 feet, the climatic requisites being moisture and equable temperature, with a mean of about 17.7° C. The wild coca shrub commonly reaches the height of 12 feet, and some are 18 feet, but the cultivated coca is usually kept down to about 6 feet. The leaves are gathered three times a year; the first harvest, or preliminary picking, is taken at the time of the trimming of the bushes, from the cut-off twigs. Then about the end of June, a scanty crop is gathered, while the last crop of the season is gathered in October or November. Harvesting must always take place in dry weather, so that the fresh leaves when spread out in layers two or three inches thick on the drying pavement can be collected in six or eight hours.

The coca plant, which is propagated from the seed in nurseries, begins to yield in eighteen months, and continues productive for half a century. The leaves, when mature, are carefully picked by hand so as to avoid breaking them or injuring the young buds, are slowly dried in the sun, and are then packed in bags holding from twenty-five to one hundred and fifty pounds each. Coca was in general use among the natives of Peru at the time of the conquest, and has continued to be much employed to the present time. It is affirmed that nearly ten million dollars' worth, or forty million pounds, are annually produced, some plantations yielding three or four harvests a year. For details as to method of cultivation, etc., see *T. G.*, Jan., 1886; also *C. D.*, 1897, 182. Coca leaves are chiefly imported from Peru, where the plant has been under cultivation since prehistoric time. Two varieties of the coca leaf occur in the commerce of the United States, namely, the so-called Huanuco coca and the Truxillo coca, the Huanuco variety being produced in Bolivia, Huanuco, Brazil, Venezuela and Argentina, while the Truxillo coca is produced chiefly in Northern Peru. The great variation in the leaves and other portions of the coca plant, produced by its long-continued cultivation, has produced much doubt and discussion as to the specificity and characteristics of the plant: H. H. Rusby has made an elaborate study of the subject (*D. C.*, Nov., 1900).

Huanuco coca has been for a long time believed to be obtained from *Erythroxylon Coca;* this belief is confirmed by Rusby and was accepted by the Pharmacopœial authorities.

Truxillo coca is the product of the *E. Coca Spruceanum* of Burck; the name "spruceanum" had, however, been used elsewhere before it was suggested by Burck and in obedience to the ordinary rules of botanical nomenclature it was changed by Rusby, who regards it as a distinct species, to *E. Truxillense.*

Coca is cultivated in the British East and West Indies, and in Java, and the product is said to appear, in the London markets, under the names of Truxillo coca and *Java coca.* This coca is entirely distinct from the Truxillo coca of the American market, and does not reach the United States. According to Emma Reens, *E. spruceanum* or *E. novogranatense* are cultivated in Java (*B. Sc. Pharm.*, 1919, xxvi, 497). The coca shrubs of India and Ceylon are the offspring of plants originally sent out from Kew Gardens, which plants were derived from seeds obtained in Huanuco, and were considered by Morris as representing a variety of *E. Coca* to which he gave the name of *E. Nova-Garatense.* According to Rusby, however, this plant is a distinct species, and the same as that previously described by Jacquin, from Colombia, under the name of *E. carthagenense* (the name *E. carthagenense* not being, as it is held in the Kew Index, a synonym of *E. areolatum*).

The leaves of the different varieties of coca do not, on the whole, resemble one another at all closely, but are distinguished from most other leaves by a slightly curved line on each side of the midrib, running from the base to the apex. This line has the appearance of a rib, but is really not of this character, having been produced during development by the peculiar folding of the leaf in the bud. The two commercial varieties were very well described in the *U. S. VIII* as follows:

"*Huanuco Coca.*—Greenish-brown to clear brown, smooth and slightly glossy, thickish and slightly coriaceous, stoutly and very shortly petioled; blade 2.5 to 7.5 Cm. long and nearly elliptical, with a very short and abruptly narrowed basal portion and a short point, the margin entire; midrib marked above by a slight ridge, very prominent underneath, the remaining venation rather obscure, especially above; underneath, a conspicuous line of collenchyma tissue runs longitudinally on either side of the midrib and about one-third of the distance between it and the margin, the enclosed areola being of a slightly different color from the adjacent surface; odor characteristic; taste bitterish, faintly aromatic, followed by a numbness of the tongue, lips and fauces.

"*Truxillo Coca.*—Pale green, thin, brittle and usually much broken, smooth, but not shining, shortly and stoutly petioled; blade 1.6 to 5 Cm. long and one-third to one-half as broad, obovate to oblanceolate, narrowed from near the middle into the petiole, usually with a slight projecting point at the summit, the margin entire; underneath two irregular lines of collenchyma tissue, usually incomplete or obscure, and frequently wanting, run beside the midrib at about one-third the distance from it to the margin; odor more tea-like than that of Huanuco Coca; taste and numbing effect similar." *U. S. VIII.* "The midrib itself is prolonged into a minute horny apiculus, which, however, is frequently broken off. Most of the epidermal cells of the under surface are seen in transverse section to project in the form of small papillæ." *Br.*, 1898.

Coca contains a number of alkaloids (see under *Cocaina* Part I). In addition Hesse (*P. J.*, April, 1903, p. 285) has also extracted four definite compounds not alkaloids, from the leaves of coca obtained from Java. These bodies are 1. *Cocacitrin*, $C_{23}H_{32}O_{17}$, a yellow crystalline compound with three molecules of water, melting at 186° C. This appears to be a glucoside yielding a sugar, *cocaose*, which may be identical with *dextrotalose*, since its osazone melts at 180° C. 2. *Cocacetin*, $C_{16}H_{12}O_7$, forming yellow needles with three molecules of water of crystallization. This melts at 260° to 265° C. 3. *Cocaflavin*, $C_{34}H_{38}O_{19}$, which forms yellow crystals with four molecules of water. It yields dextrose and galactose on hydrolysis with diluted sulphuric acid, and is, therefore, probably a glucoside. 4. *Cocaflavetin*, containing two methoxy groups, forms greenish-yellow needles with three molecules of water and melts at 230° C. The tannin of coca leaves strikes a green-black with ferric salts, and has received the name of *cocatannic acid.* Romburgh detected traces of *methyl salicylate* in the distillate from coca. (*Chem. Ztg.*, 1895, 130.)

Assay. U. S. VIII.—"Coca, in No. 60 powder, *ten grammes;* chloroform, ether, normal sulphuric acid V.S., ammonia water, distilled water, tenth-normal sulphuric acid V.S., fiftieth-normal potassium hydroxide V.S., cochineal or odeosin T.S.,

each, *a sufficient quantity.* Place the *Coca* in an Erlenmeyer flask, add 50 cc. of a mixture of chloroform 1 volume and ether 4 volumes and insert the stopper securely. Allow the flask to stand ten minutes, then add 2 cc. of ammonia water mixed with 3 cc. of distilled water, and shake the flask well, at frequent intervals, during one hour. Then transfer as much as possible of the contents of the flask to a small percolator which has been provided with a pledget of cotton packed firmly in the neck, and inserted in a separator containing 6 cc. of normal sulphuric acid V.S., diluted with 20 cc. of distilled water. When the liquid has passed through the cotton, pack the Coca firmly in the percolator with the aid of a glass rod, and, having rinsed the flask with 10 cc. of chloroform-ether mixture, transfer the remaining contents of the flask to the percolator by the aid of several small portions (5 cc.) of a chloroform-ether mixture, using the same proportions as before, and continue the percolation with successive small portions of the same liquid (in all 50 cc.). Next, shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid liquor into another separator. Add to the chloroform-ether mixture 10 cc. of a sulphuric acid mixture, using the same proportions as before, agitate well and again draw off the acid liquid. Repeat this operation once more, drawing off the acid solution as before into the second separator, introduce a small piece of red litmus paper, add ammonia water until the liquid is distinctly alkaline, and shake out with three successive portions of ether (25, 20, and 15 cc.). Collect the ether-solutions in a beaker, place it on a water-bath filled with warm water, and allow the ether to evaporate entirely. Dissolve the residue in 3 cc. of ether, and let this also evaporate completely. To the alkaloidal residue add 4 cc. of tenth-normal sulphuric acid V.S. and 5 drops of cochineal or iodeosin T.S., then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 4 (the 4 cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.03 and this product by 10, to obtain the percentage of ether-soluble alkaloids contained in the Coca." *U. S. VIII.* For methods of assaying coca leaves, see Lyons, *Ch. Ph.*, Sept., 1885; Squibb, *Ephem.*, 1887; Dohme, *Proc. A. Ph. A.*, 1893, 159; Prescott, *Organic Analysis; Proc. A. Ph. A.*, 1895, 268; *P. J.*, 1896, 1901, 222, 254; *Ph. Ztg.*, 1901, 965.

In South America many of the Indians habitually chew the leaf of the coca plant, generally mixed with some alkali as ashes or lime. It is stated on good authority that they will go for days performing hard physical labor without any other food. It is, however, clearly proven that these leaves do not take the place of nutriment, but simply put off the sense of fatigue and hunger. Eventually, however, this habit undermines the health and finally the inveterate excessive coca-chewer can be recognized by his uncertain step, general apathy, sunken eyes surrounded by deep purple aureoles, trembling lips, green and crusted teeth, and excessively fetid breath, with peculiar blackness about the corners of the mouth. An incurable insomnia is apt to be developed, emaciation becomes extreme, dropsy appears, and even death results from a condition of general marasmus. It has been believed that the effects of coca chewing are different from those produced by the alkaloid cocaine and hence it has been by some argued that the coca leaf contains other active principles, but there is no difference between the results of the habit as practised by the South American Indian and the use of the alkaloid by depraved Caucasians, which cannot be readily explained on the ground of difference in the mode of taking the stimulant or racial variation. While there are other active substances present in the coca leaf, it is not manifest that they modify the action of the crude drug materially. For a study of the uses and effects of its alkaloids see *Cocaina* Part I and *Tropacocaine* Part II.

Coca has a slight bitter tonic effect as well as a stimulant action upon the central nervous system and has been used as a tonic in *neurasthenia* and other debilitated conditions. The danger of the formation of the habit, however, far outweighs any value the drug may possess, and the use of the crude preparation of coca seems to us hardly justifiable except under the most extraordinary conditions. The *U. S. P., VIII*, recognized a fluidextract, the dose of which was from thirty to sixty minims (2–3.9 cc.), and a wine the dose of which was two to eight fluidrachms (7.5 to 30 cc.).

Cochlearia. *Cochlearia officinalis* L. *Common Scurvy-grass. Herbe au Scorbut*, Fr. *Herba Cochleariæ*, P. G. *Löffelkraut*, G. *Spoonwort.*—This annual or biennial cruciferous plant is a native of northern and middle Europe and grows in Arctic America generally. The whole herb is active. It has, when fresh, a pungent, unpleasant odor if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water, and is probably produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (*Chem. Cb.*, 1856, 124.) According to Hofmann, the oil is a sulphur-containing oil of the butylic series, having the formula $C_5H_9NS = C_4H_9CSN$.

Common scurvy-grass has been much used in *scurvy*, and even in *chronic rheumatism*. The fresh plant may be eaten as a salad, or used in infusion; the expressed juice has also been used.

Codeonal.—Under this name a mixture which is asserted to contain 2 parts of *Codeine-diethyl-barbiturate* with 15 parts of *sodium-diethyl-barbiturate* has been introduced. The purpose of the combination is to obtain the sedative action of codeine and barbital in combination. It is used as a somnifacient, as a cough sedative, and as an analgesic. The *dose* recommended is from two to eight grains (0.13–0.5 Gm.).

Codeine Hydriodide. $C_{18}H_{21}O_3N.HI + 2H_2O$.—A crystalline powder, slightly soluble in cold and very soluble in warm water, is made by the action of hydriodic acid on codeine (alkaloid). It has been used subcutaneously in lung affections and internally in *doses* of one-sixth to one-fourth grain (0.011–0.016 Gm.), several times daily.

Codeine Methyl Bromide. *Codeine Brommethylate.* $C_{18}H_{21}NO_3\ (Br.CH_3)$.—Under the trade name of *Eucodein*, this has been introduced as a cough sedative. The experiments of Jacoby (*Med. Klin.*, 1905, p. 208) indicate that it is a less powerful drug than codeine, but because of its more feeble convulsant effect can be used in larger *doses.* It has been used in doses of one or two grains (0.065–0.12 Gm.) three times a day.

Cœlocline. *Xylopia polycarpa* Oliver. (*Cœlocline polycarpa* DC.). *Berberin Tree. Yellow-dye Tree of Soudan.*—This is a small tree, of the Fam. *Anonaceæ,* growing in Soudan, Sierra Leone, and certain parts of Western Africa. When wounded, the tree exudes a juice which produces a yellow stain upon linen that cannot be washed out. The outer surface of the bark is greenish-gray interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in ribbon-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its color and bitterness. Stenhouse has ascertained that it contains *berberine.* The bark is much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, in powder or decoction, for *obstinate ulcers.*

Colalin.—A mixture of hyoglycocholic and hyotaurocholic acids obtained from bile, with a little magnesium carbonate to retain the pulverulent condition. *Dose,* one-fourth to one-half grain (0.016–0.032 Gm.).

Collinsonia. *Collinsonia canadensis* L. *Stone-root. Horseweed. Horse-balm. Richweed. Heal-all. Knot-root. Knob-weed. Guérit-tout, Baume de Cheval,* Fr. *Collinsonie,* G.—A labiate plant, which grows in woods from Canada to the Carolinas. The whole plant has a strong disagreeable odor, and a warm pungent taste. C. N. Lochman (*A. J. P.,* 1885, 228) found in the root a resin, tannin, starch, mucilage, and wax; in the leaves resin, tannin, wax, and volatile oil. The alkaloid discovered by H. J. Lohmann in the root of the *Collinsonia canadensis* appears to have been a magnesium salt. (See *D. C.,* 1902.) Collinsonia is tonic, astringent, diaphoretic, and diuretic. It is said to be locally irritant. A decoction of the fresh root has been used in *catarrh of the bladder, leucorrhea, gravel,* and *dropsy.*

Colloids.—The studies of Thomas Graham in 1862 in connection with dialysis, in which he originated the terms "crystalloid" and "colloid," remained without any special industrial or therapeutic application for many years. Recently much work has been done upon this somewhat neglected subject and some wonderful results have been obtained. The *colloids* of Graham's time were mainly organic substances analogous to glue or gelatin, although some inorganic colloids were known, such as the colloidal form of ferric hydroxide formerly known as *dialyzed iron.* As the osmotic pressure observed in colloidal solutions is extremely small we may infer that the colloids possess large molecular weights. They do not form true solutions, but form pseudo-solutions known as *sols,* or *hydrosols* when they are placed in water. The substance separating from a sol or hydrosol is called a *gel* or *hydrogel,* and the phenomenon of separation is called gelatinization. In the case of suspension of a very fine solid in a liquid by means of colloids the sol is called a *suspensoid,* or if globules of liquid are suspended, it is called an *emulsoid.*

Colloids are also known as reversible colloids or non-reversible colloids according to the stability when evaporated or redissolved. As a rule colloidal solutions are decomposed by the presence of ionizable compounds in appreciable amounts. Some colloidal substances as gelatin, casein, etc., promote stability of colloidal forms of other substances and are therefore known as protective colloids. Many colloidal preparations of the metals such as silver, mercury, etc., are prepared in this way and are much more stable than the colloidal form of the pure elements.

Hydrosols have all the external appearance of true solutions because they are homogeneous and may be filtered without leaving any solid residue on the filter and show no visible particles under ordinary microscopic observation. The small suspended particles of hydrosols may be seen clearly with the ultramicroscope (a microscope in which a luminous ray is concentrated by means of a lens and the illumination of the microscopic field produced by directing the ray at right angles to the direction of vision) as shown by the researches of Siedentopf and Zsigmondy in 1903. The particles thus observed are visible as luminous points which are in constant motion, called Brownian movements. The size of the particles varies from one ten-thousandth mm. to one two-hundred thousandth mm. A colloidal solution of gold containing 0.005 Gm. per cc. contains about 1000 million particles of suspended gold per cu. mm., which is equivalent to an immense increase of exposed surface and which accounts for some of the marvellous effects of colloidal metal solutions, particularly as catalysts.

Colloidal metals, gold, silver, iron, etc., are all found in the market at the present time under various designations. They are prepared by either electrical or chemical methods. The electric method comprises the use of the electric arc which, passing between two pieces of a given metal under water, produces the microscopic pulverization of the metal, resulting in a colloidal solution (so called) or hydrosol of that particular metal. The chemical method consists in the application of a powerful chemical reducing agent to a solution of the salt of the desired element. Colloidal suspensoids of metallic salts, as calomel (see calomelol), or bismuth oxide (see bismon), are also coming into use.

In view of the increasing number and importance of colloidal silver preparations, the assay for silver content has been given considerable attention by various authorities (see *Merck's Rep.,* 1914, 69; *Arch. Pharm.,* 2529, 69 and 497).

The colloidal metals in some cases produce catalytic effects similar to those produced by certain enzymes, as, for instance, the inversion of cane sugar by colloidal platinum. The metallic hydrosols are therefore sometimes called metallic ferments.

The colloidal solutions of the metals usually exhibit dichroism to a certain degree, that is, they are clear by transmitted and turbid by reflected light. The coloration of the famed ruby glass is due to a colloidal state of the particles of metallic gold therein contained. The ripening of the silver bromide gelatin plates in photography and of certain clays in ceramics, which require several months' empiric treatment to produce the proper degree of elasticity, is now known to be due to the formation and action of colloids.

In 1905, Robin (*Nouv. Rem.,* 1905) reported the results of some observations of the effects of subcutaneous injections of hydrosols. He found that they produced an increased excretion of urea and uric acid and marked leucocytosis. He likewise reported favorable clinical results in *pneumonia* and *articular rheumatism* from their employment. His results were confirmed by Izar and Hergage, 1909, who also found that it was of no importance which metal was employed. This fact taken together with the statements of Paderi (*Lo Sperimentale*, 1909) that silver hydrosol is without bactericidal or antiseptic properties, and especially in view of the extremely small quantity of metal in solution in many of the preparations used, point strongly toward the conclusion that such benefit as has resulted from the use of colloidal metals is not to be attributed to the influence of the metals themselves. On the other hand, many of those who have assigned beneficial effects to the use of these preparations describe reactions very similar to those which have since been found to be brought about by the parenteral administration of various proteins. (See *Protein therapy*). It seems to justify the hypothesis that the colloidal metals when injected subcutaneously bring about a stimulation of the defensive processes of the body of the same nature as those caused by foreign proteins, in fact, Auld (*B. M. J.*, Feb. 16, 1918) is led to the conclusion that the metals themselves play no part in the clinical benefit but that the favorable results are due to the peptone which has been added as protective.

Among the preparations of colloidal metals which are on the market are: *Electrargol*, a form of colloidal silver (see under *Silver, Colloidal*); *Electraurol*, a form of colloidal gold; *Collaurum*, another form of colloidal gold; *Electrocuprol*, a form of colloidal copper; *Electromercurol*, a form of colloidal mercury (see also *calomelol*); *Electromartiol*, a form of colloidal iron; *Cuprase*, a form of colloidal copper.

Cologne Water. *Spiritus Odoratus. N. F. IV. Perfumed Spirit. Eau de Cologne*, Fr. *Kölnerwasser*, G.—*Cologne water* is official in the N. F. IV (see Part III). A more fragrant spirit, and one more closely resembling the original, would be made if the quantity of oil of orange flowers were doubled.

Colubrina.—*Mabee bark*, yielded by the *Ceanothus reclinatus* L'Herit. (*Colubrina reclinata*, Brongn.) (Fam. *Rhamnaceæ*) of South America, has been analyzed by Elborne and Wilson, who find in it a glucoside. It is used in the West Indies as a stomachic. (See *P. J.*, April 11, 1885.)

Colutea. *Colutea arborescens* L. *Bladder Senna. Baguenaudier, Séné Indigène*, Fr. *Falsche Senna*, G.—A leguminous shrub growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens. The leaflets are purgative, and in some parts of Europe are used as a substitute for senna, which is said to be sometimes adulterated with them. Barbey (*P. J.*, 1895, 261) isolated *coluteic acid*, which occurs in white crystals, insoluble in water, soluble in alcohol, chloroform, and carbon disulphide. Bladder senna is comparatively very feeble. A decoction made from one to two ounces (30–60 Gm.) of the leaves may be given at a dose.

Combretum. *Jungle-weed.*—The roasted leaves and stalks of the *Combretum sundaicum* (Miquel) have been used in China in the treatment of the *opium habit.* Harrison (*P. J.*, lxxx, 52) was unable to find any alkaloid or glucoside in the plant, and Stanislaus (*J. A. Ph. A.*, 1912) confirmed the absence of active principle, but found a considerable proportion of tannic acid.

Heffner has reported favorably upon its use, but H. C. Wood, Jr., (*J. A. Ph. A.*, 1912), was unable to note any beneficial action from it which might not be justly ascribed to the tannic acid which it contains.

The *Combretum Raimbaultii* is a shrub native of West Africa, where it is known under the name of *Kinkelibah* and is used by the natives in the treatment of *black-water fever* and was introduced a number of years ago into Europe by a missionary, Father Raimbault. Dammermann has reported favorably on its value in this condition (*D. M. W.*, 1906, p. 921), but Heckel was unable to find any active constituent except a tannin. (*Jahresber, d. Pharm.*, 1891 p. 64.) Other species of the combretum appear also to have been used for the same purpose, notably the *C. Altum* Guill. et Perr. (*C. micranthum*, G. Don).

Commelina. *Day-flower.*—Under the name of *Yerba del Pollo, Commelina tuberosa* L. is said to be very largely used in Mexico in the treatment of *internal hemorrhage*, especially from the womb. From thirty to sixty grains (2.0–3.9 Gm.) of the extract may be taken in the course of one day. (See *A. J. P.*, 1897, 290.) The North American species, *Commelina communis* L., has also had hemostatic properties attributed to it. For chemical and microscopical study, see *A. J. P.*, July, 1898.

Comptonia. *Comptonia asplenifolia* Gaertn. (*Comptonia peregrina* (L.) Coulter). *Sweet Fern. Ferngale. Meadow-fern.* (Fam. *Myricaceæ.*)—A shrubby indigenous plant, named from the resemblance of its leaves to the spleenwort fern. It grows in sterile soil, from Nova Scotia to North Carolina and Michigan. All parts of it possess a resinous, spicy odor. R. T. Chiles has found in it tannic and gallic acids, volatile oil, extractive, gum, resin, and a substance resembling saponin. (*A. J. P.*, xlv, 306.) H. K. Bowman found it to contain 8.20 per cent. of tannin. (*A. J. P.*, 1869, 193.) It is said to be tonic and astringent; its decoction is used in *diarrhea.*

Condy's Fluid.—A solution made by dissolving 53 parts of potassium permanganate and 333 parts of crystallized aluminum sulphate in 777 parts of hot water.

The potassium alum, which crystallizes out when the liquid cools, is separated. The liquid is therefore a solution of the permanganate of aluminum with some aluminum sulphate. It is used as a disinfectant.

Condy asserted that in this disinfecting solution all of the available oxygen in the permanganate is utilized, whereas only 60 per cent. of the oxygen is utilized in the simple alkaline permanganate.

Congluten.—A vegetable casein obtained from almonds, containing 18 per cent, nitrogen and 0.6 per cent. sulphur. It is a white powder, soluble in weak alkaline solutions, and used in the form of a 6 per cent. solution in endovenous nutrition.

Conessi Bark. *Holarrhena antidysenterica* (Roxb.) Wall. (Fam. *Apocynaceæ.*)—Under the names of *Conessi bark, Tellicherri bark, Kurchi*, etc., a spongy, rusty-colored, bitter bark of this apocynaceous tree was formerly used in Europe as a remedy in *dysentery* and *diarrhea*, and is said still to be largely employed by the native practitioners of India. Stenhouse in 1864 obtained from the seeds, besides a fixed oil which they contain in large quantity, an alkaloid, called by him *wrightine*, which seems to be the same substance previously described by Haines under the name of *conessine* $C_{24}H_{40}N_2$. The alkaloid conessine is now a commercial product prepared by Merck, and the formula $C_{24}H_{40}N_2$ is given it. It occurs in delicate, white, interlaced masses of crystals, melting at 121° C., sparingly soluble in water, readily so in alcohol. For study of the chemical properties of this alkaloid see Giesma and Halberkann (*A. Pharm.*, 1919, cclvi, 201).

The same alkaloid occurs in the *H. africana* (A.) DC. is stated by German missionaries to be used in parts of tropical Africa in *dysentery*. Pyman (*J. Soc. Chem. Ind.*, 1919, xxxviii, 231) has found conessine and a new alkaloid *holarrhenine* $C_{24}H_{38}ON_2$ in the *H. Congolensis*. Burn (*J. P. Ex. T.*, 1915, vi, p. 305) has found that conessine and holarrhenine have very similar physiological actions. They are only moderately toxic, have a pronounced local anesthetic action, but are of no practical value because of their irritating effects. In small doses they cause a marked rise in the blood pressure due to an action upon the arterial walls, and in large doses lower blood pressure through their disturbing influence on cardiac rhythm. Brown (*B. M. J.*, June 24, 1922) has found that conessine has a powerful amoebicide action approximately equivalent to that of emetine and that it is decidedly less poisonous. When oxidized by iodic acid in sulphuric acid solution, conessine is changed to *oxyconessine* $(C_{12}H_{20}NO.)_2$.

Connarus. *Connarus guianensis* Lamb. *Seribéle.*—The seeds and root bark of this plant (Fam. *Connaraceæ*), from French Guinea, are used as tænifuges; two ounces of the seeds in decoction, without straining. (Maclaud, *P. J.*, 1896, 243.)

Contrayerva. *Contrayerba. Contrayerve*, Fr. *Bezoarwurzel, Giftwurzel*, G.—The root of *Dorstenia Contrajerva* L. (Fam. *Moraceæ*), a native of Mexico, the West Indies, and Peru. The term *contrayerba*, in the language of the Spanish Americans, signifies *counterpoison* or *antidote*, and was applied to this root under the impression that it had the property of counteracting all kinds of poison. The probability is that the root sold as contrayerva is derived from several species of *Dorstenia*, among which, besides *D. Contrajerva*, two others are mentioned by Houston, *D. Houstoni* L. and *D. Drakena* L., the former growing near Campeachy, the latter near Vera Cruz. According to Pereira and Martius, the *contrayerva* of the shops is the product of *D. brasiliensis* Lam., and is brought from Brazil.

The root, as found in commerce, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown color externally, and pale within; and has numerous, long slender, yellowish rootlets attached to its inferior part. The odor is aromatic; the taste warm, slightly bitterish, and pungent. The rootlets have less taste and odor than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and precipitates on the addition of water. Mussi (*L'Orosi*, 1894, 259) investigated this plant and found two substances, which he called provisionally *cajapine* and *contrayerbine*. Contrayerva is a stimulant tonic and diaphoretic, and has been given in *low fevers, typhoid dysentery*, and *diarrhea*, and other diseases requiring gentle stimulation. *Dose*, of powdered root, half a drachm (2 Gm.). In the root of the *Gabbon ivy* (*Dorstenia klaineans?*) Heckel and Schlagdenhauffen have found a coumarin-like body, *pseudocoumarin*. (*Ph. Cb.*, xliii.)

Copal.—The *copals* are a class of hard resins used principally in varnish manufacture. They are of various origins, both geographically and botanically. Their principal characteristics are their hardness, high melting point and comparative insolubility unless subjected to destructive distillation. There are three chief varieties: (1) *Fossil copal*, found in the ground in localities from which the trees yielding it have entirely disappeared. (2) *Semi-fossil copal*, collected from the ground in the neighborhood of living copal trees. (3) *Fresh copal*, found on living trees, either as the result of natural exudation or from artificial incisions. The fresh copal is of least value and the fossil copal is most highly prized.

The term *animé* (*animi* or *gum animé*) has been applied to a variety of resinous substances, several of them of fossil origin.

East African copals, known in commerce as *Animi gum*, or *resin*, are fossil varieties coming from Zanzibar, Madagascar and along the East African Coast. M. Kahan has investigated *Accra copal* and *Benin copal* (*A. Pharm.*, 1910, ccxlviii, p. 443) and gives the percentages of the various constituents found.

Zanzibar copal is obtained from *Trachylobium Hornemannium* Hayne (Fam. *Leguminosæ*). The trunk and limbs are covered with a clear resinous exudation, portions of which, after solidifying, drop to the ground and are collected, while other portions are broken from the tree. This kind of resin is always smooth, and is exported to India. The variety, known in the English market as *animé* (*gum animi*) is dug from the earth, and, though the product of forests now extinct, originated probably from the same tree. It is in roundish, irregular, or flattish pieces, sometimes several pounds in weight, often rough over the surface, probably from the impression of sand in its soft state, colorless, or brownish-yellow, more or less transparent, very hard, with a shining, conchoidal fracture, inodorous and tasteless. By heat it melts and emits gases, loses from 15 to 20 per cent. of weight, and is altered so as to become more soluble in ether, alcohol, or oil of turpentine, and in this way copal varnishes are usually made. It is not a proximate principle, but consists of various resins united in different proportions. According to Unverdorben and Filhol, some five different resins can be obtained by the successive action of solvents.

Sierra Leone copal or *West Africa copal* is derived from the *Copaifera Guibourtiana* Benth., a large tree growing preferably in mountainous regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hillsides, in the soil of which it has been deposited.

The Sierra Leone copal is described by Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their color graduates from a pale green to a lemon or dull yellow."

Inhambane copal has been shown to be the product of *Copaifera Gorskiana* Benth. and seeds sent to Kew Gardens in 1886 germinated, and the plant has been widely introduced into both the East and West Indies, and into Australia. (*P. J.*, xix, 508.)

American copal is a resin supposed to be derived from the *hymenæa courbaril* L., a leguminous tree of South America, although this origin was denied by Hayne. According to W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. It is in small, irregular pieces of a pale lemon-yellow color, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odor, and a mild, resinous taste. It softens in the mouth, adheres to the fingers when in powder, and readily melts with heat, diffusing its agreeable odor in an increased degree. It consists of two resins, one soluble, the other insoluble, in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker color, less transparent, and with small cavities in the interior, in other respects resembling the preceding. A study of South American varieties of copal has been made by S. Machenbaum (*A. Pharm.*, ccl, Nos. 1–6 and 13), in which the constituents are stated to be *copalic acid, copalolic acid, copaloresene, copalmic acid,* volatile oil and ash.

Fossil copal from Guiana has been studied by J. C. Essner (*Annal. Chim. Anal.*, xvii, p. 166), who gives the following constants: Sp. gr. 1.089; colorless portion, acid value 118, saponification value 127, iodine value 84.3, yellow portion, acid value 125, saponification value 151, iodine value 81.5.

East Indian copal.—This is supposed to be derived from *Vateria indica*, L. (Fam. *Dipterocarpaceæ*), but never reaches American commerce. According to W. C. Ondaatje, the bark of this plant is in daily use by the natives of Ceylon to arrest the alcoholic fermentation of the juice of the Jaggery palm, *Caryota urens*, L., a favorite beverage. (*P. J.*, 1883, 818.)

The *Dammara* (*Dammar*) resins which come from India and the East Indies are obtained from species of *Hopea, Shovea* and *Balanocarpus.* The dammars are acid resins partly soluble in alcohol and completely soluble in fixed and volatile oils. (See also *Kauri Gum.*) For an account of the present views on the nature of copal resins, see Tschirch, *Die Harze und die Harzbehälter*, Leipzig, 1900.

For descriptions of the so-called Manila copal and Australian copal which are derived from the conifers, see under *Kauri.*

Copal lotion.—Under the trade name *Adhæsol* there appears on the market a lotion containing: Copal, 350 parts; benzoin, 30 parts; tolu, 30 parts; ol. thyme, 20 parts; alpha-naphthol, 3 parts; ether, q. s., 1000 parts. It is used as an antiseptic varnish in *diphtheritic affections* of the throat.

Copper Abietinate. $Cu(C_{19}H_{27}O_2)_2$.—This forms green scales, soluble in oils, imparting to the solutions a rich emerald color. It has been used as an anthelmintic and vermifuge in veterinary practice. It is also used technically for impregnating and preserving wood.

Copper Acetate. *Cupri Acetas. U. S.* 1880. $Cu(C_2H_3O_2)_2.H_2O = 198.14$. *Crystallized verdigris. Crystals of Venus. Verdet, Cristaux de Vénus,* Fr. *Essigsaures Kupfer, Aerugo Crystallisata, Crystallisirter Grünspan,* G.—This salt may be prepared by dissolving verdigris in acetic acid, or by precipitating a concentrated solution of lead acetate with copper sulphate. It is the normal cupric acetate, as distinguished from the basic salt. "Deep green, prismatic crystals, yielding a bright green powder, efflorescent on exposure to air, odorless, having a nauseating, metallic taste and an acid reaction. Soluble in 15 parts of water and in 135 parts of alcohol at 15° C., in 5 parts of boiling water and in 14 parts of boiling alcohol. When heated above 100° C., the salt loses its water of crystallization, and at a temperature above 200° C., it is gradually decomposed. The aqueous solution of the salt has a bluish-green color, which is rendered deep blue by an excess of ammonia. On heating the salt with sulphuric acid, acetous vapors are evolved. If the aqueous solution of the salt be treated with hydrogen sulphide until all the copper is precipitated, the filtrate should leave no residue on evaporation (alkalies, alkaline earths, and iron). If the aqueous solution be heated to boiling with solution of soda in excess, it will yield a filtrate which should not be clouded by hydrogen sulphide (absence of lead, zinc)." *U. S.*, 1880.

Verdigris. Impure Subacetate of Copper. U. S. 1870. *Copper Subacetate. Viride Æris, Ærugo, Cuivre, Vert-de-gris, Verdet,* Fr. *Grünspan, Basisches Essigsaures Kupfer, Kupferoxyd,* G. *Verde Rame,* It. *Cardenillo,* Sp.—It occurs in masses of a *pale green* or *bright blue color,* and composed of a multitude of minute silky crystals.

The *blue variety* has approximately the composition $(C_2H_3O_2)_2Cu_2O$. When treated with water it is generally decomposed. The *green variety* of verdigris has the composition $CuO.2Cu(C_2H_3O_2)_2$. Its taste is coppery. It is insoluble in alcohol, and, by the action of water, a portion of it is resolved into the neutral acetate which dissolves, and the tribasic acetate which remains behind in the form of a dark green powder, gradually becoming black. The green rust, called in popular language verdigris (*vert-de-gris*), with which copper vessels are very frequently coated, when not kept clean, is a copper carbonate, and should not be confounded with true verdigris. Verdigris, apart from its impurities, is a variable mixture of the basic copper acetates.

The local and general action of copper acetate upon the animal economy and the treatment of its poisoning are the same as those of copper sulphate. It is not used internally. Dr. G. Billard (*Presse Medicale,* 1909) uses the fine dust of copper subacetate by inhalation of minute quantities in the treatment of *tuberculosis;* he states that the cough is usually lessened and sometimes disappears completely.

Copper Aluminated. *Lapis Divinus. Divine Stone.*—This copper compound, in the form of a green powder or plates, is a combination of copper and aluminum sulphates and potassium nitrate. It is soluble in water and is used solely as a mild caustic in *ophthalmology.*

Copper Ammonio-sulphate. *Cuprum Ammoniatum. U. S.* 1870. *Ammoniated Copper Sulphate. Cuprum Sulfuricum Ammoniatum. Sulfate de Cuivre ammoniacal, Cuivre ammoniacal,* Fr. *Schwefelsaures Kupferoxyd-Ammoniak, Ammoniakalisches Kupfersulfat,* G.—The character of the salt which results from the interaction between copper sulphate and ammonia varies according to the conditions under which the reaction takes place. The formerly official process was as follows: "Take of Copper Sulphate *half a troyounce;* Ammonium Carbonate *three hundred and sixty grains.* Rub them together in a glass mortar until effervescence ceases. Then wrap the Ammoniated Copper in bibulous paper, dry it with a gentle heat, and keep it in a well stoppered glass bottle." *U. S.*,

1870. The salt which results from this process is probably the same as that which is made by adding copper sulphate to a solution of ammonia and has the composition $CuSO_4.4NH_3 + H_2O$. If this preparation be allowed to remain exposed to the air, it will lose ammonia and water, and be changed into a mixture of basic sulphates. Ammoniated copper sulphate loses two molecules of NH_3 and the one molecule of water at 150° C. and at 260° C. only anhydrous sulphate remains, which frequently, however, contains cuprous oxide.

This salt has a beautiful deep azure-blue color, a strong ammoniacal odor, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction to vegetable colors; but, unless there is excess of ammonium sesquicarbonate, the solution deposits copper subsulphate if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into ammonium sulphate and copper carbonate. This change is apt to occur, to a greater or less extent, while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat the whole of it is dissipated, except the copper oxide. Arsenic trioxide precipitates a green copper arsenite from its solution. Solutions of potassium and sodium hydroxides, lime water, and the acids are incompatible with it. Ammoniated copper was at one time employed internally in various nervous diseases, especially *epilepsy*, as well as locally for its astringent action, but is at present very seldom exhibited. In overdoses it produces vomiting, and the poisonous effects which result from the other preparations of copper. *Dose*, in pill or solution, a quarter or half a grain (0.016–0.032 Gm.), twice a day, and gradually increased to four or five grains (0.26 or 0.32 Gm.).

Copper Arsenite. *Cupri Arsenis. Copper orthoarsenite.* $Cu_3(AsO_3)_2$. *Scheele's Green.*—This salt was brought forward for the purpose of treating *diarrhea* on the homeopathic principle, in the *Symptomen-Codex* of Jahn, in 1865, and has been greatly lauded by John Aulde and other regular practitioners in the treatment of *diarrhea, enterocolitis, cholera morbus,* and *dysentery.* It is to be given in doses of from one three-thousandth of a grain (0.000022 Gm.), at intervals of from ten to twenty minutes, until some effect is produced. It does not seem to be sustaining its first reputation. According to H. A. Hare, *copper arsenite* is a valuable remedy in *anemia.* The *dose* ordinarily is from one one-hundredth to one-twentieth grain (0.0006–0.003 Gm.).

Copper Citrate. *N. N. R.* 1924. $Cu_2C_6H_4O_7 + 2\frac{1}{2}H_2O$.—*Cupric citrate* contains from 34 to 36 per cent. of copper. It is a bluish-green, finely crystalline powder, without odor or taste. Very slightly soluble in cold water, soluble in acids and alkalies. Used for the same purposes and in the same doses as other salts of copper over which it possesses the advantage of its sparing solubility in water. Proprietary preparations of similar properties are known by the names of *cuprocitrol* and *cusylol.* Copper citrate has been used in the treatment of *conjunctivitis* and *trachoma* in aqueous solutions of from ½ to 5 per cent. An *ointment of copper citrate* in glycerite of boroglycerin has been proposed by Hoffman (*A. J. P.*, 1917, p. 298) for the treatment of *trachoma* and disturbances of the follicles of the ciliæ. It is prepared as follows: Copper citrate, 8 Gm.; glycerite of boroglycerin, 80 Gm.; wool fat, 2 Gm.; white petrolatum, 10 Gm. Heat the glycerite of boroglycerin to 125° C. and slowly add the copper citrate and continue the heat until it dissolves. Then remove the heat, and when it has cooled to 75° C. add the wool fat and white petrolatum and stir constantly until it has cooled to 50° C., and transfer to air tight containers.

Copper Iodide. *Cupri Iodidum. Cuprous Iodide. Kupferjodür,* G. Cu_2I_2.—A white powder, insoluble in diluted acids and in water; soluble in ammonia water and solution of potassium iodide. Made by adding a solution of potassium iodide to a solution of copper and iron sulphates.

Copper Nitrate. *Cupri Nitras. Br.* 1885. *Cupric Nitrate.* $Cu(NO_3)_2,3H_2O$.—"May be obtained by dissolving copper in diluted nitric acid and evaporating the solution until crystallization takes place on cooling to a temperature not lower than 70° F. (21.1° C.)." *Br.*, 1885. This salt, as obtained by the above process, forms prismatic crystals of a deep blue color, and very deliquescent and corrosive. At a temperature below 21.1° C., with one-third of its weight of water it forms tabular crystals which have the composition $Cu(NO_3)_2.6H_2O$. The addition of a very little more water causes the crystals to form a styptic and caustic fluid. The diluted aqueous solution should show only a faintly acid reaction to litmus paper. This salt has the medicinal properties of copper sulphate, and may be used in the same dose.

Copper Nucleinate. *Cuprol.*—This salt is a greenish powder and is said to contain 6 per cent. of the metal and to be readily soluble in hot water and not to be thrown out of its solution by alkalies and not to precipitate with albuminous liquids. It has been highly recommended in the treatment of *trachoma* and other conditions of the conjunctiva. The assertion is made that it has greater penetrating powers and produces less irritation than ordinary salts of copper. (Von Sicherer, *Die Ophthal. Kl.*, 1901.)

Copper Oleate. *Cupric oleate,* $Cu(C_{18}H_{33}O_2)_2$, with excess of oleic acid. A greenish-blue mass, consisting of 10 per cent. copper oxide dissolved in an excess of oleic acid. It is soluble in ether and is used for its antiseptic action as a 10 to 20 per cent. ointment in indolent *ulcers* and unhealthy *granulations.*

Copper Oxide, Black. *Cupri Oxidum Nigrum. Cuprum Oxydatum. Oxyde noir de Cuivre, Safran de Vénus,* Fr. *Kupferoxyd,* G.—*Cupric oxide,* CuO, is obtained most conveniently by heating the nitrate to redness. This oxide, in the form of ointment, made by mixing four parts with thirty of lard, was formerly used locally in chronic *lymphadenitis.* It is also asserted to be an active *tænicide* of very feeble toxic power. It is given by Dörr in *doses* of one and a half grains (0.096 Gm.) four times a day for several days, the last dose followed by castor oil. (See *Ther. Geg.*, 1901.)

Copper Phenolsulphonate. *Cupri Phenolsulphonas. Copper Sulphocarbolate. Paraphenolsulfosaures Kupfer,* G. $(C_6H_4(OH)SO_3)_2Cu + 6H_2O$.—Green prismatic crystals soluble in water and alcohol. Made by reaction between copper sulphate and barium phenolsulphonate. A solution of from ½ to 1 per cent. is applied locally in *gonorrhea,* and also as a styptic, hemostatic and antiseptic under the name of *cupriaseptol.*

Coral. *Corail,* Fr. *Koralle,* G.—The solid mesodermal calcareous skeletons of the coral polyps, *Anthozoa,* were formerly used in medicine, but have passed out of vogue. Their chief constituent is calcium carbonate, colored by ferric oxide, and united with more or less animal matter.

Corallin. *Pæonin. Aurine R.*—A coloring or dyeing material, derived from *rosolic acid* or *aurin* ($C_{19}H_{14}O_3$)—which is made by acting upon phenol with sulphuric and oxalic acids—by exposing together rosolic acid and alcoholic ammonia to a heat of 149° C., and is considered to be an intermediate product between pararosaniline and pararosolic acid. A solid substance is thus obtained, in scales of a peony redness, with reflected green or dull yellow rays, almost insoluble in water, soluble in alcohol and the fixed oils. It has been accused of causing violent toxic symptoms when used as a dye, but it is doubtful whether the effects were due to the dye or to arsenic or other contaminating substances. (See *M. T. G.*, 1869, 421; *P. J.*, 2d ser., xi, 360; also *N. Y. M. J.*, 1870, 599; *N. R.*, i, 228.)

Local poisoning may be caused by *aniline red* (see *Fuchsin*) as well as by corallin. The two colors may be distinguished in tissues. Aniline red disappears very rapidly by contact with ammonia; but the color reappears by the addition of an acid, or by the evaporation of the alkali. Corallin red is not dissolved by cold water, yields a slight color to boiling water, but rapidly disappears from the tissue under the action of boiling alcohol. Alkalies brighten the color without changing it; acids precipitate the coloring matter in yellow flakes.

Corallorhiza. *Corallorhiza odontorhiza* (Willd.) Nutt. *Coral root.* (Fam. *Orchidaceæ.*)—This is a parasitic leafless herb, sending up from a coral-like rhizome a simple scape or flower stem, from six to sixteen inches high, furnished with sheaths instead of leaves, of a light brown or purplish color, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. The rhizome is the part used. It is much branched and toothed, and of a brown color, and its resemblance to coral gave name to the plant. It has a strong peculiar odor, and an astringent bitterish taste. It was much valued by the eclectics as diaphoretic in *fevers; dose,* of powder, thirty grains (2 Gm.) every two hours.

Coramine. *Pyridine-betacarbonic acid diethylamide.*—This substance has been introduced as a circulatory stimulant for use in the treatment of acute depressions such as occur in surgical *shock, pneumonia* and other infectious diseases, poisonings and other forms of *heart failure.* It is marketed in the form of a 25 per cent. solution, of which 1 to 2 cc. (15–30 minims) may be given by mouth or by subcutaneous injection.

Cordol. *Tribromsalol.* $C_6H_4.OHCOO.C_6H_2Br_3$.—A white tasteless, and odorless powder, insoluble in water, ether, and alcohol, freely soluble in chloroform and glacial acetic acid. *Cordyl* or *acetyl tribromsalol* is insoluble in water, and occurs in the form of fine white needles. *Cordeine* or *methyl tribromsalol* occurs in small white crystals, which are insoluble in water, but soluble in alcohol and chloroform. Cordol, cordyl, and cordeine are used as intestinal antiseptics, easily decomposed, giving the combined actions of tribromphenol and salicylic acid when split up in the intestinal canal. The *dose* of either is from eight to fifteen grains (0.5–1.0 Gm.).

Coriaria. *Coriaria myrtifolia* L. *Currier's Sumac. Redoul, Sumac des Corroyeurs,* Fr. *Gerberstrauch,* G. (Fam. *Coriariaceæ*).—This is a shrub growing wild in Southern Europe, which is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. They have also been reported both in Europe and in America as an adulterant of sweet marjoram, the *coriaria* leaves being finely broken to facilitate admixture. The presence of coriaria in marjoram may be inferred by strewing a specimen of the broken up leaves upon the surface of a dilute ferric chloride solution, which does not affect the fragments of marjoram but which quickly stains the coriaria fragments a deep greenish-black, owing to their high tannin content. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. Riban, in 1864, found in the fruit a glucoside *coriamyrtin.* It occurs as extremely bitter, white crystals, fusing at 220° C., sparingly soluble in water but freely so in alcohol and other organic solvents. Its empirical formula is $C_{30}H_{36}O_{10}$. Marshall (*J. P. and Ex. T.*, 1912, iv, p. 135) studied the substance supplied by Merck under the name of coriamyrtin which, however, he believed to be different from that described by Reban, because it was soluble in water. The lethal dose was 1 mgm. per kilo. He found that it was a stimulant to the medullary centers, increasing the blood pressure and respiration and slowing the pulse; in large doses it caused cerebral convulsions. Coriamyrtin has been employed as a stimulant in *collapse* in doses of one-sixtieth of a grain (0.001 Gm.).

Tlolocopetale, a Mexican drug, is said to be the product of a Coriaria, probably *C. myrtifolia,* containing *coriarin* and *coriamyrtin,* and to be actively poisonous.

Toot-poison. Tu-tu.—In New Zealand a poisonous plant, known as the *toot-plant,* has proved very destructive to the domestic animals. W. Lauder Lindsay found it to resemble either *Coriaria ruscifolia* of Linnæus or *C. sarmentosa* Forst., and in its action on the system to be an irritant narcotic. It appears that more than one species of *Coriaria* inhabit New Zealand, *C. thymifolia* Humb. et Bonpl. and *C. angustissima* Hook. f., besides the *ruscifolia;* though Lindsay appears to think that the two former may be merely varieties of the third. It is not only cattle that are poisoned by the plant, but not infrequently also children, and occasionally even an adult. W. S. Key attributes poisonous qualities to an oil (*Chem. News,* 1890, xxii), but it has been shown by T. Hill Easterfield and B. C. Aston that the three New Zealand species of coriaria contain a glucoside, *tutin,* $C_{17}H_{20}O_7$, which is not identical with coriamyrtin, and which, according to Marshall, is toxic, especially to the medulla oblongata and the basal ganglia of the brain. (*Proc. Chem. Soc.*, xvi, 213.) It is affirmed by T. H. Hartwick (*P. J.*, vol. xv, 22) that goats are not poisoned by the tu-tu, and that they have even been used to eradicate the plant by browsing, also that the berries when ripe are not only not poisonous to man, but if care is taken to reject the seeds, are a grateful and refreshing fruit. The prominent symptoms of the poisoning in man are giddiness, stupor, and coma, with or without delirium or convulsions. Occasionally the delirium resembles that of alcoholic intoxication, in other instances approaches that of acute mania, and is attended with violent muscular action. Loss of memory is a characteristic of the convalescence. The toxicity of tutin, which was demonstrated by Marshall, has been confirmed by Ford (*J. P. and Ex. T.*, 1910, ii).

Cork. *Suber. Liege,* Fr. *Kork,* G.—The great use made of this substance in pharmacy and the arts justifies a brief notice of it. It is chiefly produced by *Quercus Suber* L. (Fam. *Cupuliferæ*) but is obtained also from the *Q. occidentalis* F. Gay. It consists of the exterior layers of the bark, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy consistence which characterizes *cork.* The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years —the interval requisite for the renewal of the suberous layers by the living portions of the bark beneath—furnishes a fresh supply, even for a century and a half, before it perishes. There are three important layers of the bark: the epidermis, the cork, the cellular envelope, and the blast which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial product is the result of an artificial injury to the bark. The exterior layers are removed, and the bast exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed by the proliferation of a phellogen. The outer portions of this cork layer perish, while annually a new layer is added to the cork already existing, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large concave plates, which are then flattened under pressure, and dried. At present cork comes into commerce from Portugal, Spain, France, Italy, Tunis, Algeria, and Morocco.

A cork has recently come into the United States commerce from Nicaragua. It has been found by E. F. D. Baker to be obtained from the roots of the *Anona,* a tree closely resembling in appearance the ordinary cottonwood of the United States.

In selecting cork for use, those parts should be preferred which are soft and of uniform consistence, and in the choice of the larger plates those should be selected which are thick, flexible, elastic, finely porous, and of a reddish color. Boiling hot alcohol extracts from rasped cork tissue some 10 per cent. of soluble principles. From the hot alcohol solution a substance crystallizes which was first noticed by Chevreul under the name of *cerin.* According to Kugler (*Dissertation on Suberin,* Halle, 1884), besides cellulose and lignocellulose, cork contains two constituents, *cerin,* to which he gives the formula $C_{20}H_{32}O$, and *suberin,* which is a fat, and contains stearic acid and *phellonic acid,* $C_{22}H_{42}O_3$. This constituent, suberin, prevents the penetration of liquid into the cork, and is only extracted by alcoholic alkali solutions. When treated with nitric acid, cork yields a peculiar acid, which has been denominated *suberic acid.* This is a dibasic acid homologous with oxalic acid, and has the formula $C_8H_{14}O_4$. It is formed by the oxidation of many other substances, such as the oils from linseed, castor bean, cocoa nut, almond, spermaceti, etc.

Stanislaus Martin has called attention in France to the use of refuse corks in Paris, where they are collected by the scavengers, and sold to persons whose business it is to revive them, recutting such as are of unsuitable shape, filling up the interstices with mastic, and covering them over with some powder which may give them a fresh appearance. Corks are sometimes bleached with sulphurous acid, and the odor of hydrogen sulphide has been noticed in prescriptions which have been compounded, when such corks have been used in the dispensing bottle. (*P. J.*, 1881, 1080.) Mohr has found that old corks may be regenerated by allowing them to soak for twenty-four hours in hot water, washing well several times, allowing to stand for a few hours in a mixture of one part of hydrochloric acid and fifteen parts of hot water, and finally washing well in pure water. It is evident that a cork at one time used to enclose arsenical or other deadly solution may become saturated with the poison, and afterwards impart enough of it to another liquid, if not to produce dangerous effects on the health, at least to give to tests evidence of its presence, and thus lead to serious suspicions. No cork, therefore, which has been used in a bottle containing a poisonous substance should be employed a second time.

In order to overcome the brittleness of corks which are kept in stock they should be kept in a humid atmosphere and they are improved by moistening in clean water just before use and then removing the excess of water by wiping them dry.

Cornutol. *N. N. R.* 1924.—It is a proprietary preparation consisting of a biologically tested liquid extract of ergot containing the water-soluble, alcohol-insoluble constituents of ergot and about 10 per cent. of alcohol. *Dose,* ten to thirty minims (0.65 to 1.8 cc.) hypodermically or double that amount by mouth.

Coronilla. *Coronilla scorpioides* Koch (Fam. *Leguminosæ*).—In 1886 Cardot, in a thesis (Nancy) announced that the *Coronilla scorpioides* (Medic.) Koch, a papilionaceous plant of Southern France, is an active cardiac poison. In 1889 Schlagdenhauffen and Reeb (*Rev. Gen. de Clin. et de Thérap.*, July, 1889) insolated a glucoside, *coronillin,* to which they assigned the formula $C_7H_{12}O_5$. It was a yellowish powder, soluble in water, acetone, and amyl alcohol; slightly soluble in chloroform and ether. Heated with diluted hydrochloric acid an amorphous resin was separated, *coronillein.* This also occurs as a yellow powder, but is not bitter to taste. It is insoluble in water but dissolves in alcohol, acetone, and chloroform. The physiological studies by Gley, by Schlagdenhauffen and Reeb, and by Maramaldi (*R. T.*, cxxxvi) have demonstrated that coronillin acts upon the heart in a manner similar to digitalis. In small doses it slows the pulse through stimulation of inhibition and in larger quantities increases the tonicity of the cardiac muscle and eventually arrests the ventricle in systolic spasm. According to Maramaldi it also depresses the spinal cord and respiration.

Locally, coronillin appears to be actively irritant. In Maramaldi's experiments it failed to assert its physiological action when administered to the dog by the mouth, a result believed by the investigator to be due to its decomposition by the acid in the stomach. As it has been found by various clinicians to be active in man when given by the mouth, it is probable that the comparative feebleness of human gastric juice permits of its absorption unchanged. The *doses* given by various clinicians have diverged greatly, probably because of differences in purity of the various samples used; of the commercial coronillin the *dose* is commonly stated at present to be one and one-half grains (0.096 Gm.) from four to six times a day, but it must be noted that Schlagdenhauffen affirms that three-fourths of a grain (0.048 Gm.) is a toxic dose. *Coronilla varia* of Europe also probably contains coronillin. (V. Poulet, *B. G. T.*, 1891.)

Colmenthol.—*Coryfin. Menthyl ethylglycocolate,* $C_{10}H_{19}O—CO—CH_2—O—C_2H_5$, is a colorless, inodorous fluid, slightly soluble in water and readily soluble in alcohol and ether. Alkalies immediately release the menthol. It is used as a local anesthetic and sedative to mucous membranes of the upper respiratory tract, especially in *catarrhal conditions* of the *nose.* It has the advantage over menthol in these conditions of being much less irritating. It is employed locally by means of a small swab in strengths of from 50 to 100 per cent. Inhalations of its vapors are also recommended in *laryngitis* and even in *bronchitis.*

Corylus. *Corylus rostrata* Ait. *Beaked Hazel.* —This is a small indigenous shrub of the Fam. *Betulaceæ,* growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicules like those of cowhage (see *Mucuna*). These spicules have been employed by Huebener as an anthelmintic. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See *A. J. P.*, xiv, 280.)

According to Baruttan and Davidson (*M. M. W.*, 1909, p. 2482), the *hazel-nut* contains an alcoholic soluble substance which acts as a stimulant to the uterine muscle. An alcoholic extract has been placed upon the market under the name of *mensan* which these authors have found useful in the treatment of *uterine hemorrhages* due to chronic endometritis. The dose employed was a tablespoonful twice a day.

Coscinium. *Br. Add.*—The dried stem of *Coscinium fenestratum* Colebr. The stem of this menispermaceous plant has long been used in Ceylon and Southern India as a yellow dye and bitter tonic, and has found its way into Europe under the names of *false columba* and *tree turmeric.* It contains berberine and is an efficient stomachic. The Br. Add. recognized an *infusion* (*Infusum Coscinii,* Br. Add.), *dose,* one-half to one fluidounce (15–30 cc.); a concentrated solution (*Liquor Coscinii Concentratus,* Br. Add.), *dose,* one-half to one fluidrachm (1.8–3.75 cc.); and a *tincture* (*Tinctura Coscinii,* Br. Add.), *dose,* one-half to one fluidrachm (1.8–3.75 cc.).

Coto Bark.—In the years 1873 and 1874 a bark bearing this name appeared in the London drug market, coming from Bolivia. During the Mulford Biological Exploration of the Amazon Basin in 1921–22, Dr. O. E. White under direction of Doctor Rusby collected several barks and branchlets of Lauraceous trees, on the mountains south of Huachi, from which barks have been collected for the market under the name of Coto. One of these which is known to the natives as "Coto Piquante" or "Coto Fino" is stated by H. H. Rusby to be a form of genuine coto. He has named the tree yielding it, *Nectandra Coto.* The physical characteristics of this bark are now under investigation. (For a description of *Nectandra Coto* Rusby, Sp. Nov., see *Bull. Torrey Bot. Club,* 1922, xlix, p. 260.)

The *Coto bark* which formerly appeared on the market was described as occurring in pieces 3 dm. or more long, from 3 to 6 cm. wide, and from 5 to 15 mm. thick. The outer surface was irregular, often looking as though it had been shaved or split off, and in other parts covered with a fine adherent corky layer free from lichens; the inner surface also irregular, with numerous rather closely placed, longitudinal projecting bast fibers. The color approached cinnamon-brown; upon fresh cross-section the bark seemed to be filled with yellowish spots, except in the outer portions. The odor was aromatic, and much more apparent if bruised; the taste hot, and somewhat aromatic; the powder very pungent to the nostrils. For microscopic structure, see *P. J.*, vi, 301; also *Ph. Era,* May, 1888.

The true coto bark has disappeared from commerce but under the name of *paracoto* bark a somewhat similar drug has replaced it. This bark was recognized by the N. F. IV which defined it as "the dried bark of an unidentified tree indigenous to Northern Bolivia." *N. F. IV.*

Rusby says that this bark is known by the natives as *Coto ordinario* and he assigns it to a new species *Ocotea Pseudo-coto* Rusby also belonging to the *Lauraceæ.* He further asserts that it is without medicinal value.

The N. F. IV described paracoto as: "In quills, or fragments of quills, of indefinite length, usually from 3 to 6 cm. in breadth, from 5 to 15 mm. in thickness; of a deep brown color throughout, the outer surface nearly smooth, lightly transversely fissured, and often very thinly scaly, the inner surface very coarsely striate; hard and heavy, but splitting and breaking readily, the fracture mealy in the outer layer, with an irregular resinous band, coarse splintery in the inner layer with large, yellowish-brown bast fibers and stone cells and darker resin tissue. Odor strong and characteristic, nutmeg-like; taste strongly aromatic and pungent. Paracoto yields not more than 3 per cent. of ash." *N. F. IV.* It is said that the two barks can be distinguished by their odor, that of the coto recalling cinnamon and that of the paracoto resembling more the odor of nutmeg.

Jobst and Hesse obtained a crystallizable body, *cotoin,* from true coto bark, by making an ethereal extract from the powdered bark, treating this with warm petroleum benzin, decanting and spontaneously evaporating the benzin, and allowing the mixture to stand until clear. Cotoin (methyltrioxy-benzophenone or benzoyl-phloroglucinol-monomethyl ether), $C_{14}H_{12}O_4$, is sparingly soluble in cold water, more soluble in hot water, insoluble in petroleum benzin, very soluble in alcohol, chloroform, benzol, acetone, and carbon disulphide. Nitric acid becomes blood-red in contact with cotoin, sulphuric acid is colored brownish-yellow, and ferric chloride blackens a dilute solution of cotoin. *Hydrocotoin methyl-hydrocotoin, protocotoin* and *methyl-protocotoin* are also present. O. Hesse described a coto bark which did not contain cotoin but *cotellin,* $C_{20}H_{20}O_6$. (*Ph. Ztg.*, 1905, 845.)

The composition of this bark has recently been investigated by H. A. Seil (*J. A. Ph. A.*, 1922, xi, 904) who states it to contain a non-phenolic alkaloid called *parostemine,* a phenolic alkaloid, *parostemine,* and a crystalline substance, cotoin. This bark is undoubtedly a true Coto, since it contains cotoin. Under the name of *coto-coto,* the bark of a rubiaceous plant (*Palicourea densiflora*) is employed in Brazil in *rheumatism.* Whether this be the Bolivian plant or not is uncertain.

Paracotoin, $C_{12}H_8O_4$, is extracted from paracoto bark, in which it exists associated with *hydrocotoin,* $C_{15}H_{14}O_6$, *protocotoin,* $C_{16}H_{14}O_6$, *methylhydrocotoin,* $C_{16}H_{16}O_4$, and *methylprotocotoin,* $C_{17}H_{16}O_6$ and *leucotin* (phenyl coumalin). Paracotoin may be distinguished from cotoin by giving no reaction with ferric chloride. *Piperonylic acid* (*methyleneprotocatechuic* acid), $C_8H_6O_4$, is present in both barks.

Coto bark is decidedly irritating: its powder, rubbed upon the skin, is said to produce heat and redness, and, according to Burkart, fifteen grains (1.0 Gm.) taken into the stomach produce persistent burning pain, followed by repeated vomiting. The remedy was first introduced as serviceable in *diarrhea,* and seems to have established its reputation. Although observers are not explicit upon this point it is evident that when there is a tendency to acute inflammation it must be used with great caution. Inpens (*D. M. W.*, 1913, 1827) from his physiological studies concludes that it acts by lessening intestinal peristalsis. The *paracoto bark* is said to resemble it in its action, but to be much less powerful, which statement is contradicted by Doctor Rusby.

The N. F. IV recognized a *fluidextract of paracoto* (*Fluidextractum Paracoto*) and assigned a dose of five minims (0.3 cc.). Balz (Tokio, Japan) is said to have treated *cholera* successfully by hypodermic injections of three grains (0.2 Gm.) of paracotoin. The value of cotoin in the treatment of *diarrhea* has been confirmed by various clinicians. It has been used in *catarrhal diarrheas* and the *diarrheas* of *tubercular ulceration,* of *typhoid fever,* and of other conditions. (See *B. G. T.*, vol. xi, 167.) It does appear to have some special effect upon the alimentary canal, as, according to Pribram (*Prager Med. Wochens.*, 1880) and Albertoni (*A. E. P. P.*, xvii, 293), it markedly lessens the excretion of indican. Albertoni also believes that it actively dilates the abdominal vessels and thereby hastens absorption, and Bibrana, that it is an antiseptic. It is not probable that cotoin has any general action upon the system, and Jobst found that even fifteen grains (1.0 Gm.) injected hypodermically into the rabbit produced no other than local symptoms. *Dose,* of cotoin, from one to three grains (0.065–0.2 Gm.); of fluidextract of coto, from five to twenty minims (0.3–1.3 cc.), four to six times a day.

Cotula. *U. S.* 1870. *Mayweed. Wild Chamomile. Dog Fennel. Camomille puante, Maroute,* Fr. *Hunds-Kamille, Stinkende Kamille,* G. *Camomilla fetida,* It. *Manzanilla loca,* Sp. *Herba Chamomillæ Fœtidæ. Anthemis Cotula* L.—Mayweed is an annual composite plant, which grows abundantly both in the United States and in Europe. In this country it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. The flower heads have recently appeared in several commercial samples of Matricaria as an admixture. They may be distinguished from the latter by being conical with a solid receptacle bearing broad and bristly-acuminate scales, pubescent bracts having scarious margins and obtusely three-angled achenes, all of which are entirely devoid of a pappus. W. H. Warner found in the flowers volatile oil, oxalic, valeric, and tannic acids, coloring matter, acrid fatty matter, bitter extractive, and salts of potassium, calcium, magnesium, and iron. (*A. J. P.*, 1858, 390.) Pattone (1859) claimed to have found an alkaloid, *anthemidine,* and a crystallizable bitter acid, *anthemidic acid,* but his results have not been confirmed. The whole plant has a strong, disagreeable odor, and a warm, bitter taste, and imparts these properties to water.

The medicinal properties of this species of *Anthemis* are essentially the same as those of chamomile, for which it may be substituted, but its disagreeable odor is an obstacle to its general use. On the continent of Europe it has been given in *hysteria* as an antispasmodic. It has also been thought to be emmenagogue. It is said to have the property of vesicating, if applied to the surface fresh and bruised. The whole plant is active, but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion.

Cotyledon Umbilicus L. *Navelwort. Pennywort. Cotylet, Nombril de Vénus,* Fr. *Nabelkraut,* G.—This is a perennial, herbaceous, succulent plant, of the fam. *Crassulaceæ.* The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks.

According to Flétet, it contains trimethylamine, combined with an unknown acid. When the powder of the plant is exposed to the air, it attracts moisture, and exhales a disagreeable odor strikingly analogous to that of fish, and an extract treated with a fixed alkali disengages, even in the cold, an odor which, at first ammoniacal, soon acquires the fishy character referred to. It has been highly lauded in *epilepsy* (for references, see 16th ed., *U. S. D.*), but it has very uncertain if any therapeutic properties. *Dose,* of fresh juice, from one-half to one fluidounce (15–30 cc.), two or three times a day; of fluidextract, one fluidrachm (3.75 cc.); of dry extract, five grains (0.32 Gm.); to be increased and given steadily for months.

Cow Tree. *Palo de Vaca. Palo de Leche.*—The milky juice of the *Brosimum Galactodendron* D. Don (fam. *Urticaceæ*) is much used in South America instead of cream in tea and coffee, etc. It is obtained by making incisions in the tree, is white and viscous, turns sour on exposure to the air, and deposits a caseous substance. According to the analysis of Boussingault, its composition varies very much, but it always contains a large percentage of fatty matters (32.2 per cent.), and much less casein, albumen, sugar, and phosphates. (*P. J.*, ix, 679.)

Crab's Claws. *Chelæ Cancrorum.*—These, finely powdered, were formerly used in medicine. In 100 parts are 60 parts of calcium carbonate and 14 of calcium phosphate, with 26 of animal matter.

Crabstones. *Lapilli Cancrorum. Crab's Eyes. Oculi* (*Calculi*) *Cancrorum. Yeux* (*Pierres*) *d'Ecrevisses,* Fr. *Krebsaugen, Krebssteine,* G.—Concretions found in the stomach of the European *crawfish* (*Astacus fluvatilis*), at the time the animal is about to change its shell; chiefly procured in the province of Astrakhan, in European Russia. The crawfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a whitish or reddish color, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They consist of calcium carbonate and phosphate, cemented together by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose as prepared chalk.

Creosote Benzoate.—This is a yellowish liquid, soluble in alcohol and ether. It is used mainly for its antiseptic action as a spray in the treatment of nose and throat diseases.

Creosote Iodide. *Creosotide.*—A product obtained by causing iodine to enter into combination with the cresol constituents of beechwood creosote. It contains approximately 25 per cent. of its weight of iodine. It is an amorphous brownish powder, practically insoluble in water and having a faint characteristic odor and taste. It is prescribed in incipient *tuberculosis* with alleged good results; also in *asthma* and as a gastric and intestinal antiseptic. *Dose,* one-fourth to one-half grain (0.016–0.032 Gm.) three or four times a day.

Creosote - phenyl - propionate. *Proposote.*—This is employed as a stimulating expectorant and is stated to have the advantage over creosote that it does not disturb the stomach as it is not affected by acid media, but passes into the intestine and is broken up by the duodenal juices with the liberation of creosote. It is administered in *doses* of five to ten minims (0.3 to 0.6 cc.).

Creosote Phosphate. *Creosoti Phosphas. Phosote.* $PO_4(C_6H_7)_3$.—A combination of creosote and phosphoric acid, in the form of a syrupy, colorless liquid, with almost no odor or taste of creosote. It contains about 80 per cent. of creosote and 20 per cent. of phosphoric anhydride. The *dose* is fifteen to thirty minims (1–2 cc.). *Creosote Phosphate* and *Creosote Tannophosphate* (*Tophosote*) have also been introduced as antiseptics.

Creosote Phosphite. *Phosphotal.*—This is a reddish-yellow, oily liquid with a faint creosote-like odor, dissolving readily in both water and alcohol. It represents over 90 per cent. of creosote. It is intended as a substitute for that remedy, especially in the treatment of *phthisis.* The *dose* is three to ten minims (0.2 to 0.6 cc.).

Creosote Tannate. *Creosotum Tannicum. Creosal. Tannocreosote. Kreosal. Tannosal.*—The tannic acid ester of creosote. It is obtained by heating equal quantities of beechwood creosote and pure tannin to 80° C. and adding gradually phosphorous oxychloride and purifying the product. It is a brown amorphous powder soluble in water, glycerin and alcohol, and containing 60 per cent. creosote. It passes through the gastric juice undecomposed but in the alkaline intestinal secretion it is split up into its components and acts as an antiseptic astringent in the treatment of *diarrhea.* It is also used for its creosote effect in *phthisis* and may be given in daily *doses* of fifteen grains (1 Gm.), representing 9 grains (0.6 Gm.) of creosote.

Creosote Valerate. *Creosotum Valeras.* (*Eosote.*)—A mixture of the valeric esters of the phenols contained in creosote. It forms a mobile oily liquid, boiling at about 240° C. and soluble in alcohol and ether. This substance as an internal medicine is practically identical in its properties with the creosote carbonate. *Dose,* three to ten minims (0.2–0.6 cc.).

Cresatin. *N. N. R.* 1924. *Metacresylacetate.*—The acetic acid ester of metacresol, $CH_3C_6H_4OCH_3CO$. A colorless oily liquid, insoluble in water, soluble in immiscible solvents. Volatile with steam. Used as an external application, either pure or diluted, as an antiseptic and analgesic.

Cresol Iodide. *Iodocresol. Traumatol.* $C_6H_3I.(CH_3)OH$.—This is formed by the action of potassium iodide solution upon an emulsion of cresol and water. It contains but one atom of iodine, while *losophan* or *cresol triiodide* contains three atoms, and, consequently, a higher percentage of iodine. It is a violet-red, odorless, amorphous powder; insoluble in water, acids, and alcohol; dissolving with difficulty in ether, readily in alkaline solutions, and freely in chloroform. It contains 55 per cent. of iodine, and has been commended as powerfully antiseptic, non-irritant, and having local anesthetic properties. It is used locally in *syphilitic* and other *ulcers, eczema,* especially when attended with much discharge, *intertrigo,* and various other skin diseases. Also as a substitute for iodoform in surgery. In *herpes* a 10 per cent. traumatol collodium has been found very useful, and a 5 to 10 per cent. traumatol zinc ointment has been highly commended. Pure traumatol may also be used as a dusting powder.

Cresol Preparations.—The fact that cresol, which is only sparingly soluble in water, is readily dissolved in saponaceous solutions has led to the introduction of a number of proprietary disinfectants of this nature. There is no reason to believe that any of them has any real advantage over the official compound solution of cresol, but some of them are sufficiently used to justify a few words of description.

Several of these have been bacteriologically tested by the United States Hygienic Laboratory. We give below a table showing the phenol coefficient of these as published in this bulletin (see *Phenol,* Part I).

Preparation	*Phenol Coefficient*	
	Without organic matter	With organic matter
Bacterol	1.58	1.34
Creolin-Pearson	3.25	2.52
Cresoleum	2.90	1.75
Germol	2.12	1.79
Kresolig	2.18	1.48
Kreso	3.92	2.32
Liq. Cresolis Comp. (*U. S. P.*)	3.00	1.87
Lysol	2.12	1.57
Saponified Cresol	1.03	0.57
Trikresol	2.62	2.50

Creolin is said to be an emulsion of cresol, obtained by means of rosin soap. There are in the market at least two sets of preparations, the one of German, the other of English origin. An analysis of creolin-Pearson, published by Pfrenger (*A. Pharm.,* 1890, 701), gives: phenols, 2.67; hydrocarbons, 44.94; organic bases, 2.76; sodium, 1.45; resin, 32.45; sulphur, 0.248; chlorine, 0.14; water (by difference), 5.34. The phenols consisted of ortho- and meta-cresol, with traces of phenol and the oxyleucols; the hydrocarbons, of the higher homologues of benzene, with naphthalene and anthracene; the bases belonged to the quinoline group. Creolin forms a milky emulsion on mixture with water; with chloroform, ether, and absolute alcohol it mixes in all proportions. It is sometimes called *cresoline* or *sanatol.*

The statements made concerning the germicidal powers of creolin have been extraordinarily at variance. Thus, Eisenberg asserted that a 3 per cent. solution of creolin destroyed anthrax spores in forty-eight hours, but Van Ermengen (*B. A. R. B.*, 1889, iii,) failed to kill them by thirteen days' exposure to a 10 per cent. solution. Burgess reached the conclusion that a 20 per cent. solution of creolin was equivalent to a 2.5 per cent. of phenol while Schneyder finds that creolin is from two to four times as strong as pure phenol, according to the species of bacteria on which it is tested. The last conclusion seems to be as near to the truth as it is possible to decide in view of the contradictory reports and corresponds with the findings of the U. S. Hygienic Laboratory. It has been claimed that creolin is non-poisonous, but although its toxicity is certainly much less than that of phenol, it is not entirely innocuous. Mugdan (*V. A. P. A.*, 1890, cxv, p. 131) found that doses of from 5 to 10 Gm. of Pearson's creolin are fatal to rabbits when given by the mouth, and Korach (*D. M. W.*, 1895), Van Ackeren (*B. K. W.*, 1889) and Bitter (*B. M. J.*, 1890) reported serious, although not fatal, poisoning in adults. Fliesburg (*Northwestern Lancet*, 1891, xi, p. 417) reports death in a three-weeks-old baby from 30 drops of creolin. The symptoms of creolin poisoning have resembled those of carbolic acid; namely, nausea, vomiting, frequently convulsions or coma, with albuminous, bloody or smoky urine.

Internally, creolin is probably a useful remedy when it is desired to check fermentation in the alimentary canal. Locally applied, it has been largely used with success in the treatment of *scabies*, in the form of a 5 per cent. ointment with vaseline. Although creolin has been used for various surgical purposes, its most popular employment has been as a disinfectant douche for internal cavities. In *ammoniacal cystitis*, washing out the bladder with a ½ per cent. solution of creolin has yielded excellent results. In the treatment of *acute* and *chronic dysentery* large enemas of a ½ per cent. solution may be used; in the case of infants the strength should be about one-half of this. For washing out the uterus after *labor*, the strength of the creolin solution should be 1 per cent.

Creolin is recommended by Jaksch as a deodorant to iodoform; a mixture of from 1 to 2 per cent. of creolin with iodoform produces a compound *creolin-iodoform* of a faint aromatic odor, soluble in alcohol and ether, and believed to possess the therapeutic properties of iodoform. Water removes from it the creolin and leaves the iodoform.

Ethylenediaminetricresol or *kresamin* is a mixture of tricresol with ethylenediamine. It is a colorless, aqueous liquid, having a phenol-like odor, and after standing in the air becomes of a light-yellow color without losing disinfecting power. According to H. Eckstein, it is an exceedingly powerful antiseptic, especially adapted to the preserving of specimens for microscopic use. As a local application the same author has found it very valuable in those cases of *eczema* in which there was a pronounced secondary infection of the skin, and also in *sycosis* and similar parasitic diseases. Bandages of it wet with a solution of from 1:4000 to 1:400 were kept applied to the part. In *lupus* and some similar conditions local protracted baths of from three to twelve hours' duration, with a concentration of 1:4000, were found efficacious. From 10 to 15 per cent. ointments of it were also employed.

Lysol was introduced by Gerlach (*Z. Hyg.*, 1891) and since then has been very widely used. Fox (*Penna. Health Bulletin*, 1910) has shown that lysol is inferior to the official Compound Solution of Cresol. As regards its toxicity, while it is probably less poisonous than phenol, it is an energetic poison. According to Blumenthal, there are about 100 cases annually of lysol poisoning in Berlin alone. Fries (*M. M. W.*, 1904), from a study of 38 cases of lysol poisoning, of which 17 were fatal, reaches the conclusion that the toxic dose for adults is from 10 to 12 cc. Cramer (*Cb. Gyn.*, 1898) has reported a death from its use as a vaginal douche.

Cresol Salicylates. *Cresalols. Cresol Salols.* $C_6H_4\left\{\begin{array}{l}OH\\COOC_6H_4CH_3\end{array}\right.$.—Salicylates may be prepared from ortho-, meta-, or para-cresol by a process similar to that used in the making of salol. They are insoluble in water, slightly soluble in cold alcohol, and are easily crystallized. The *meta-cresol salicylate* is the cresalol generally referred to by that name. It fuses at 74° C. and is easily soluble in alcohol and ether. Nencki states that the cresalols decompose in the alimentary canal, and are efficient substitutes for phenyl salicylate, and less poisonous. (*C. R. A. S.*, Feb., 1889.)

Cresol Triiodide. *Meta-cresol Tri-iodide. Losophan. Tri-iodo-Cresol* $C_6HI_3(CH_3)OH$.—A fine, yellowish powder, with a rather strong, but not disagreeable odor; insoluble in water, soluble in alcohol, ether, and chloroform, freely so in oil. Merck (*Jahresbericht*, 1892, 77) describes it as obtained in colorless needles, fusing at 121.5° C. It contains 78.39 per cent. of iodine. A specimen prepared by Friedrich Baeyer & Co. was found by Petersen (*M. M. W.*, July, 1891) to yield its iodine with difficulty, passing through the alimentary canal almost without absorption. It is employed externally as an antiseptic and astringent in *various skin diseases*. It is applied in a 2 per cent. solution or as a 10 per cent. ointment.

Cresotinic Acid.—*Cresotic acid. Homosalicylic Acid. Oxytoluic Acid,* $C_6H_3\left\{\begin{array}{l}CH_3\\OH\\COOH\end{array}\right.$.—Although there are ten possible isomeric cresotinic acids, according to the location in the benzyl ring of the hydroxyl and the methyl radicals, the only ones which have been used in medicine are the three methyl derivatives of ortho-oxybenzoic (salicylic) acid. These may be made artificially from cresol by a reaction analogous to that used in making salicylic acid.

Although it was at one time believed that the small amounts of cresotinic acid which were formerly present in the synthetic salicylates had a toxic effect upon the system, the experiments of Demme (*Th. M.*, 1890) and of May (*B. M. J.*, 1909, ii, p. 791) and others show that they are only slightly more toxic than salicylic acid. May has also found that both the meta- and ortho-cresotinic acids were actively germicidal. In 1876 Buss suggested the use of sodium cresotinate—a mixture of the sodium salts of the three isomers—as an antipyretic. The value of cresotinic acid in *rheumatic fever* has been carefully investigated by Stockmann (*J. P. Ex. T.*, 1912, iv, p. 97) who comes to the conclusion that *sodium meta-cresotinate* is capable of entirely replacing the salicylates but has no advantage over it; that the ortho salt is an active antirheumatic but also depressant to the heart; that the para salt is much less efficient.

Crotaline.—Under this name the *venom of the rattlesnake, Crotalus Adamanteus,* was recommended by Mays in the treatment of *phthisis, asthma, neuralgia,* and *epilepsy* several years ago. More recently, Spangler (*N. Y. M. J.*, September 9, 1911) revived this substance as an *antiepileptic.* He gave as a theoretic explanation of its use that the blood of epileptics coagulated with abnormal rapidity and that the venom delayed coagulation. Jenkins and Pendleton (*J. A. M. A.*, 1914, lxiii, p. 1749), in an extended study of 49 patients, found not only that the blood of epileptics was not more coagulable than normal, but that the number of convulsions after the use of crotallin was greater than without the drug. Thom (*B. M. S. J.*, 1915, clxxi), from a study of 203 cases, likewise reached the conclusion that the treatment was of no value. The danger of the injection is not merely from the injurious effects of the venom itself, but, as shown by Anderson (*J. A. M. A.*, 1914, lxii, p. 893), also from the fact that the commercial preparations are not sterile. The beginning *dose* recommended is one two-hundredth of a grain (0.0003 Gm.) hypodermically, which may gradually be increased as the patient forms a tolerance for the drug. The injections are generally followed by severe local irritation and should not be repeated for at least a week.

Crurin. *Quinoline-bismuth sulphocyanide.* $(C_9H_7NHSCN)_3Bi(SCN)_3$.—*Quinoline - bismuth rhodanate,* a reddish-yellow powder with weak odor of quinoline, insoluble in water, alcohol, and ether. *Crurin* of the markets is a preparation containing 25 per cent. of active ingredients with starch. According to the researches of Müller, it is bacteriologically active, and it has been especially recommended in the treatment of ulcers of the leg, by dusting them at intervals in full strength or diluted, *pro re nata.* It has also been highly recommended by E. Jacobi in *gonorrhea,* according to the following formula: Rub fifteen grains (1.0 Gm.) of crurin with seventy-five minims (4.6 cc.) each of distilled water and glycerin and gradually add sufficient distilled water to make six and one-half troyounces (201.5 Gm.).

Cryptocarya. *Cryptocarya australis* Bentham. (Fam. *Lauraceæ.*)—From the bark of this Queensland tree, T. L. Bancroft (*Austral. Journ. Pharm.*, March, 1887) has separated an alkaloid which is said to be a powerful respiratory poison.

Culilawan. *Cortex Culilaban.*—An aromatic bark, produced by *Cinnamomum Culilawan,* Blume (*Laurus Culilawan* L.), (Fam. *Lauraceæ*), a tree of considerable size, growing in the Molucca Islands, Cochin-China, and other parts of the East. It is usually in flat or slightly quilled pieces, 5 to 10 cm. long, 2.5 to 3.5 cm. wide, and 2 to 4 mm. thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The periderm is for the most part removed, but when present is of a light brownish-gray color, soft to the touch, and somewhat spongy. The color of the bark itself is a dull, dark, cinnamon brown, the odor highly fragrant, the taste agreeable, aromatic, and not unlike that of cloves. The active constituent is a volatile oil, smelling like a mixture of the oils of cajuput and cloves. Culilawan has the medicinal properties of the aromatics, but is rarely used. (See *Clove bark.*)

Cumin. *Cummin. Cuminum* Ed. *Cumin,* Fr. *Kreuzkümmel, Mutterkümmel, Römischer (langer, scharfer) Kümmel,* G.—The so-called *cumin seeds* are the fruits of *Cuminum Cyminum* L., an annual umbelliferous plant, which is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other Mediterranean countries.

The cumin fruits are oblong cremocarps of a light brown to yellowish-brown color from 5 to 6 mm. long and 1.5 mm. broad, the 2 mericarps of which are coherent. Each mericarp has 5 prominent ribs and 4 broader secondary ones, each beset with fine hairs, as well as 6 oil-tubes (vittæ). Their odor is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain about 2.5 per cent. of an essential oil, which is yellowish, and has the sensible properties of the fruits. It consists of three distinct oils, one a hydrocarbon, *cymene,* $C_{10}H_{14}$, recognized now as isopropyl-p-methyl-benzene, another *cuminol,* $C_{10}H_{12}O$, which may be regarded as *cuminic aldehyde,* $C_{10}H_{11}OH$, and the third a terpene, $C_{10}H_{16}$. Acymene identical with that of the oil of cummin seed can be prepared by dehydrating camphor or oil of turpentine. (*A. J. P.*, xlvi, 117; see especially *A. J. P.*, xliv, 452.) Cumin aldehyde has also, together with cymene, been obtained from the fruits of *Cicuta virosa* L. Trapp, *Ann. Ch. Ph.*, cviii, 386; see also *Schim. Rept.*, 1909, 49.) In medicinal properties cumin fruits resemble the other aromatic umbelliferous fruits. *Dose,* fifteen to thirty grains (1–2 Gm.).

Cumol. *Cumene. Pseudocumol.* $C_6H_3(CH_3)_3$-(1 :3 :4).—An oily fluid derived from coal tar, boiling at 168° to 178° C. Cumol has been especially recommended by Krönig (*Centralbl. f. Gyn.*, 1894) for the purpose of sterilizing catgut, which is placed in the cumol and slowly heated up to 160° C. After two hours it is removed and freed from the adhering cumol by petroleum benzin.

Cunila. *Cunila Mariana* L. *C. origanoides* (L.) Britt. (Fam. *Labiatæ*), *American or Common Dittany. Sweet Horsemint. Stonemint.*—A small indigenous perennial herb, growing on dry, shady hills, from New York to Georgia, and Illinois and Arkansas westward, and flowering in June and July. This plant has much branched stems bearing opposite, nearly sessile, ovate leaves cordate or rounded at the base and serrate along the margin. Its small flowers are borne in corymbed cymes and vary from white to purple in color. The whole herb has a warm, pungent taste and a fragrant odor, dependent on an essential oil. This was formerly used in the *dose* of five or ten minims (0.3–0.6 cc.) as a carminative, and in *doses* of from fifteen to twenty minims (0.9–1.3 cc.) as a diaphoretic.

Curare. *Woorari. Woorara. Woorali. Urari.*—The term "curare" has no specific meaning, but according to Whiteford is simply the Indian word for poison, and it is evident that there are a considerable variety of arrow poisons used in South America under the same name. As originally described by Waterton, it was in the form of a thick syrup, but as it now occurs in commerce it is a blackish extract, brittle, somewhat resinoid in appearance, encrusting the sides of gourds or little rude earthenware jars, into which it has been poured in a liquid state. The drug varies much in strength. According to the researches of Planchon (*P. J.*, xi, 491), there are really four distinct varieties of *curare.* (1) That from the Upper Amazon, obtained from the *Strychnos Castelnæi* Wedd., and possibly from *S. Yapurensis* G. Planch. (2) That from the Upper Orinoco, extending towards the Rio Negro, yielded by *S.*

Gubleri G. Planch.; this is the variety spoken of by Humboldt. (3) That of British Guiana, obtained from *S. Toxifera* Schomb., associated with *S. pedunculata* Benth. and *S. cogens* Benth. (4) That of French Guiana, made out of *S. Crevauxiana* Baill. (*S. Crevauxii* G. Planch.). These varieties are, however, commercially indistinguishable.

In 1898 Boehm classified the curares of the markets as *Tubocurare,* originating from the Amazon, preserved in hollow bamboo canes, and said to contain about 9 to 11 per cent. of *tubocurarine* as its poisonous constituent; *Gourd curare,* derived from *Strychnos toxifera,* very rarely met with, and having curarine and a second alkaloid soluble in ether for its active principle; *Jar curare,* obtained from *Strychnos castelnœi,* also exceedingly rare in the European markets, containing three alkaloids—*protocurine,* having a feeble curare action; the non-poisonous *protocuridine;* and *protocurarine,* which is more actively poisonous than is curarine. (*Ph. Ztg.*, xlii, 41.) The preparation of woorari has been witnessed by various travellers and variously described. (See *P. J.*, xvi, 502; *B. F. M. R.*, Oct., 1865; *P. J.*, x, 1881.)

Curare now comes into the market in hollow bamboo stems and in small earthen pots, the former being termed "*Bamboo curare*" and the latter "*Pot curare.*" *Bamboo curare* occurs as a dark brown granular extract, the broken fragments of which appear crystalline. *Pot curare* occurs as a dark brown to black mass having the shape of the earthen pot which contained it.

The method followed in the Upper Amazon region is to make a decoction of the bark of *Strychnos Castelnœi,* to which one-tenth of the stem of another liane is added. This is then concentrated by evaporation. To this concentrated juice then is added the leaves of *Petiveria alliacea,* the stems of *Dieffenbachia Seguine,* the root barks of two plants of the *Piperaceæ* and a species of *Marcgravia.* The fluidextract is then evaporated until it is in the condition of an extract, and poured into small vessels. Joubert asserts that the Tecuma Indians use, besides *S. Castelnœi* Weddell, *Cocculus toxiferus* and an arum (*Taya*), which he found to be very poisonous. According to Kobert (*Ph. Ztg.*, June, 1885), *Malouetia nitida* Spruce (fam. *Apocynaceæ*), or *Guachamaca,* a plant which is abundant in the Orinoco and Rio Negro districts, enters largely into the composition of curare. The alkaloid, *guachamacine,* isolated by T. Schiffer in 1883, is very closely allied to, if it be not identical with, curarine, in both its chemical and its physiological activity. It is entirely possible that the varieties of woorari vary in their alkaloid and their physiological properties.

Allied to woorari are the arrow poisons by W. S. W. Ruschenberger from Colombia, and studied by W. A. Hammond and S. Weir Mitchell. (*Am. J. M. S.*, July, 1859.) Corroval was in dark brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. They found its activity to depend upon the presence of a peculiar alkaloid, *corrovaline.* It resembles curare in that it produces general paralysis without previous spasm, but differs, in paralyzing also the heart. *Vao* or *Bao* appears to be a dilute and adulterated form of corroval.

R. Boehm has isolated the two bases, *curarine,* $C_{19}H_{26}ON_2$, and *curine,* $C_{18}H_{19}O_3N$. The free tubocurarine forms an amorphous brown-red mass. Boehm (*Ber. d. Chem. Ges.*, xx, 143) states that curine exists in many specimens of curare; it may also be obtained from the aqueous extract of curare. It is much less poisonous than the accompanying curarine. Curine is a crystalline powder fusing at 161° C., slightly soluble in cold water, freely soluble in alcohol, chloroform, and dilute acids. It forms a voluminous white precipitate with metaphosphoric acid.

Paracurarine (or *tubocurarine*) has the composition $C_{19}H_{21}O_4N$. *Protocuridine* ($C_{19}H_{21}O_3N$) and *protocurarine* ($C_{19}H_{23}O_3N$) are also present in the variety known as *pot curare. Bakankosine* ($C_{16}H_{23}O_8N$) is a nitrogenous glucoside which has been isolated from *Strychnos vacacona.*

Woorari is one of those poisons whose active principle passes through animal membranes with difficulty, and hence when given by the stomach or rectum it acts very slowly, and in some cases elimination may proceed so rapidly that no marked influence is exerted, because not enough of the alkaloid is in the blood at any one time. There is also reason for believing that the alkaloid is destroyed in the liver. When injected into a vein, or introduced by the hypodermic needle or the poisoned arrow into the cellular tissue, it acts with great promptness. The symptoms caused are progressive loss of muscular power, the animal growing weaker and weaker, the respirations becoming more and more feeble, until death by asphyxia results.

The action of curare is to paralyze the peripheral ends of the motor nerves, the muscles, when directly stimulated, retaining their irritability. In mammals, as a result of the paralysis of the phrenic nerves, there is failure of respiration, and consequent death from asphyxia. The heart usually continues beating after cessation of the breathing, only very large doses affecting the arterial pressure directly. If, however, the dose be sufficient, the drug paralyzes the peripheral ganglia, thereby causing a dilation of the blood vessels with consequent fall of pressure, increased rate of the pulse through lack of inhibitory control, loss of irritability in the secretory nerves, and other modifications of functions of less importance. Tillie (*A. E. P. P.*, xxvi,) has brought forward evidence to show that there is a primary excitation of the spinal cord which, however, in ordinary poisoning, is masked by paralysis of the motor nerves. The sensory apparatus does not seem to be affected, unless by enormous doses. Glycosuria has been frequently noticed in animals as the result of curare poisoning. According to Morishima (*A. E. P. P.*, 1889, xlii), this is apparently independent of the amount of glycogen in the liver or muscles.

According to the experiments of Joseph Tillie, *curine* has no influence upon the motor nerves, but acts both in the frog and in the mammal upon the heart, belonging physiologically to the digitalis group. Boehm states that the presence of curine in curare can be recognized by the white precipitate made by metaphosphoric acid.

Voisin and Lionville describe two types of poisoning in human beings. In the milder type the pulse is increased in force and frequency, respirations somewhat rapid, the temperature a little elevated, and the urine contains sugar. After larger quantities symptoms begin with severe chill, tremors, small pulse, and early loss of power in the lower extremities, later the cold skin becomes hot, the pulse rapid and full, there is marked reduction of the body temperature, with redness of the skin, and frequently profuse sweating. In non-fatal cases, the paralysis of the extremities rarely lasts for an hour, but the fever may continue for several days.

In cases of poisoning from the injection of woorari, a ligature around the limb between the place of injection and the heart, the free exhibition of diluents and evacuants, and artificial respiration when required, are the measures recommended. (*Ed. M. J.*, 1867, 667.)

Although curare has in the past been used as an anti-convulsant in *tetanus* and *hydrophobia*, it is a remedy of no practical value, because the phrenic nerve is no less susceptible than the other motor nerves of the body, and if given in sufficient doses to control the spasm, will likely lead to fatal asphyxia. For man the *doses* administered by subcutaneous injection were from one-twelfth to one-third of a grain (0.005–0.02 Gm.) of the crude curare. According to Bernard, curarine is at least twenty times as strong as curare.

Curcuma. *U. S.* 1870. *Turmeric. Safran des Indes, Souchet des Indes*, Fr.; *Kurkuma, Gelbwurzel*, G.; *Curcuma*, It., Sp.; *Zirsood*, Arab.; *Huldie*, Hindoo. *Curcuma longa* L. (Fam. *Zingiberaceæ.*)—The rhizome of this plant is ovate or pear-shaped, and internally of a deep yellow or orange color. The plant is a native of Southern Asia and East Indies, and is cultivated particularly in China, Bengal and Java. The best is said to come from China.

Long turmeric, representing the secondary rhizomes, is in cylindrical or oblong pieces, from 0.5 to 1.5 cm. in thickness, distinctly annulate, tuberculated, somewhat contorted, externally yellowish-brown or greenish-yellow, internally deep orange-yellow, hard, compact, breaking with a fracture like that of wax, and yielding a yellow or orange-yellow powder. *Round turmeric*, representing the main rhizomes, is ovate or pear-shaped, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. Sometimes it comes cut into two transverse segments. The two varieties are derived from the same plant. The odor of turmeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow coloring matter called *curcumin*, a brown coloring matter, gum, an odorous and very acrid volatile oil, and a small quantity of calcium chloride. Curcumin has been obtained by F. A. Daube, in deep yellow crystals of a high luster, by a process which may be found in the *A. J. P.* (1871, 308). C. L. Jackson and Menke have submitted turmeric root to a thorough examination, and give the following results: The turmeric oil was first removed from the ground root by treatment with ligroine, then the curcumin mixed with a large quantity of resin is extracted with ether, and finally purified by crystallization from alcohol. The oil extracted by ligroine was dark yellow, and amounted to 11 per cent. of the root. The purified curcumin amounted to 0.3 per cent., and melted at 178° C. Analysis of the pure curcumin, of several of its salts, and of derivatives by Daube showed its formula to be $C_{10}H_{10}O_3$. Gajewsky gave the formula as $C_{16}H_{16}O_4$ and Jackson as $C_{28}H_{28}O_8$. Ciamicin and Silber have later given the formula as $C_{19}H_{14}O_4(OCH_3)_2$ or $C_{21}H_{20}O_6$ which has been verified by other investigators. It is brown in mass, but yellow in the state of powder, without odor or taste, insoluble in benzin, scarcely soluble in water, but very soluble in alcohol, ether, and the oils. It is a diatomic monobasic acid. When treated with weak oxidizing agents it yields vanillin. The alkalies rapidly change its color to a reddish-brown, and paper tinged with tincture of turmeric is employed as a test of their presence. The paper is rendered brown also by boric acid, which it thus serves to detect. When treated with a mixture of sulphuric and boric acids it yields a product called *rosocyanin*, because it dissolves in alcohol with a fine red color, and is turned blue by alkalies. Its alcoholic solution produces colored precipitates with lead acetate, silver nitrate, and other salts. Turmeric is used for dyeing yellow, but the color is not permanent.

The rhizomes are dug up at the close of the season's growth, washed and then either scalded or boiled. During this process the starch becomes more or less altered, the contents of many of the cells becoming swollen to form pasty masses which are colored yellow by the curcumin present in the cells. The rhizomes are then quickly dried in the sun.

Statements by some of the older writers as to the presence of an alkaloid in turmeric root have not been recently confirmed.

This root is largely used as a condiment in the tropical East forming the basis of the well-known *curry powder*. In pharmacy it is sometimes employed to impart color to ointments and other preparations. It possesses no medicinal value.

Turmeric, when used as an adulterant, may be detected by means of a mixture of boric and sulphuric acids, but according to A. E. Bell, a much better test is afforded by the use of the reagent made by dissolving 1 gramme of diphenylamine in 20 cc. of 90 per cent. alcohol, carefully adding 25 cc. of pure sulphuric acid. To a little of the suspected powder, placed on a slide, a drop of the reagent is added with a glass rod. Spots of a fine purple color immediately develop, which may be readily recognized with the microscope.

Turmeric paper, used as a test, is prepared by the method described in the appendix of the U. S. P.

The tubers of the *Curcuma angustifolia*, Roxb., and the *C. leucorrhiza*, Roxb., are cultivated in India for the sake of their starch and are sometimes known as *East Indian Arrow Root*.

Curry Leaves. *Currie.*—The leaves of the *Murraya Kœnigii* Spreng. (Fam. *Rubiaceæ*), a tree of India, are very largely used in that country as an aromatic, stomachic stimulant; when powdered and mixed with spices and other substances it forms *curry powder*, which is much used for seasoning food, rice, cooked dishes, etc.; it is also employed in *dyspepsia, diarrhea*, and even *dysentery*. According to J. G. Prebble (*Pharmacographia Indica*, vol. i), curry leaves yield to distillation a small quantity of volatile oil, and also contain a greenish-black resin, and a glucoside, *kœnigin*. The clear oil extracted from the seeds is known as *simabolee oil*.

Curry powder is a term usually applied to a highly seasoned condiment consisting of a mixture of a number of spices. The formulas vary in the identity and proportion of the spices used, but usually include the majority of the following: black pepper, capsicum, nutmeg, cinnamon, cloves, cardamon and turmeric, the latter always predominating. The word "curry" which comes from the Orient, originally signified a stew containing meat, in which a blend of spices was used in preparing the sauce. Curry powder is frequently used with rice and its use is increasing in the western world.

Cusparia Bark. *Cuspariæ Cortex. Br.* 1898. *Angustura, U. S.* 1870. *Angustura (Angostura) Bark. Carony Bark. Cortex Angusturæ. Angusture vraie,* Fr. Cod. *Angusture,* Fr. *Angusturarinde,* G. *Corteccia dell' Angustura,* It. *Corteza de Angostura,* Sp.—This bark was formerly recognized by both the U. S. and British Pharmacopœias but is no longer official in either. It was originally attributed in the *Cusparia febrifuga* Humb. (*C. officinalis,* Hancock, *Galipea cusparia* St. Hilaire) but is now believed to be derived from an allied tree, *Galipea officinalis,* Hancock. *Cusparine* ($C_{19}H_{17}O_3N$), *galipine* ($C_{20}H_{21}O_3N$) and *galipoidine* ($C_{19}H_{15}O_4N$). The tree grows abundantly on the mountains of Venezuela at the height of from six hundred to one thousand feet above the level of the sea.

The bark is generally brought from the West Indies packed in casks; but, according to Brande, the original package as it comes from Angostura consists of the leaves of a species of palm, surrounded by a net-work of sticks.

Cusparia bark "occurs in flattened or curved pieces, or in quills, generally about 10 to 12 Cm. long, 2.5 Cm. wide, and 2 mm. thick. The outer layer usually consists of a gray or yellowish cork which is often soft and easily removed, disclosing a hard, dark brown inner layer; the inner surface is light brown and frequently laminated. The fracture is short and resinous; on the fractured surface many white points are visible. A transverse section exhibits numerous cells filled with acicular crystals of calcium oxalate and small oil glands, but seldom any sclerenchymatous tissue other than small isolated groups of fibers. Odor musty; taste bitter." *Br.,* 1898. Calcium oxalate raphides are abundant in the bark, but the most characteristic peculiarity is the presence of numerous cells a little larger than the other parenchymatous cells and completely filled with oil or a yellowish resin. The odor of Angustura bark is peculiar and disagreeable when fresh, becoming fainter with age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end of the tongue.

Cusparia bark contains a volatile oil, a neutral bitter principle and several alkaloids. The volatile oil, which may be obtained by distillation with water, is of a pale yellowish color, lighter than water, of an acrid taste, and with the odor of the bark. Of this oil Beckurts and Nehring obtained 1.5 per cent. It had a sp. gr. of 0.956; under a pressure of 35 mm. it commenced to boil at 153° C. and the greater part distilled between 200° and 220° C., the last portions becoming solid when artificially chilled. Beckurts and Froeger (Gildemeister and Hoffman, *Aetherische Oele,* p. 601) found as its essential ingredient a sesquiterpene alcohol, $C_{15}H_{26}O$, to which they give the name *galipol.* This boils between 260° and 270° C., and is optically inactive. They found also a small quantity of an inactive sesquiterpene, *galipene,* as well as traces of a terpene, probably pinene, and cadinene to which the oil owes its laevo-rotatory property.

The bitterness of the bark is due chiefly to a neutral principle *angosturin,* $C_{19}H_{12}O_5$, which melts at 58° C. Beckurts and Nehring (*A. J. P.,* 1892, 410) announced the discovery of four alkaloids in Angustura bark—viz., *galipine,* melting at 115.5° C. and crystallizing in slender lustrous needles of white color; *galipidine,* melting at 111° C. and crystallizing in silky lustrous plates of white color; *cusparine,* melting at 90° C. and readily soluble in alcohol, ether, chloroform, acetone, and benzene, more sparingly in light petroleum; and *cusparidine,* melting at 78° C. and crystallizing in minute slender white needles. Its salts are less soluble than those of galipine and galipidine, but more readily than those of cusparine. The four alkaloids are tertiary bases. The existence of galipidine and cusparidine has, however, been called in question; Troeger and his co-workers (*A. Pharm.,* 1913, ccli, 246 and 1920, cclviii, 250) regarding them as mixtures containing the alkaloids cusparine and galipine. Troeger and Beck find in Angostura bark three alkaloids, cusparine, $C_{19}H_{17}ON_3$, *galopoidine,* $C_{19}H_{15}O_4N$, and a new alkaloid of the formula $C_{16}H_{13}O_2N$. (*A. Pharm.,* 1913, ccli, 246.) A fluorescent glucoside was found by Beckurts and Nehring. For a description of false Angustura barks, see *U. S. D.,* 19th edition, p. 417.

Angustura bark was formerly attributed with febrifuge and antiperiodic powers but probably has no other virtues than that of an aromatic bitter. It is rarely prescribed by physicians, its chief use being in the form of various nostrums advertised directly to the laity. Under the name of *Infusum Angusturæ* the U. S. Pharm., 1870, recognized an infusion made in the proportion of half a troyounce of Angustura bark in a pint of water; *dose,* two fluidounces (60 cc.), repeated every two, three, or four hours. *Dose,* in substance, ten to thirty grains (0.65 to 2.0 Gm.). In larger quantities it is apt to produce nausea.

Cuttlefish Bone. *Os Sepiæ. Cuttle-bone. Os de Sèche (Seiche),* Fr. *Sepie, Weisses Fischbein,* G.—This is a calcareous body, situated underneath the skin, in the muscular mantle of the *Sepia officinalis* L., or *cuttlefish* (Ord. *Dibranchia*), a mollusk abundant in European seas and in the Indian Ocean. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white color, a feeble sea odor, and a saline taste. It contains, according to John, from 80 to 85 per cent. of calcium carbonate, besides animal matter, a little sodium chloride, and traces of magnesia. Its fine powder may be given as an antacid, and it is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird cages that the birds may rub their bills against them, and the powder is employed for polishing. Another product of the cuttlefish is a blackish-brown liquor, secreted by a small gland in an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in making the water-color *sepia* and a writing fluid used by the inhabitants of China, India and Japan. It is not the India ink of commerce, which is made from a specially prepared lampblack.

Cyano-Cuprol.—This liquid is stated to contain copper and cyanogen united chemically with a derivative of tuberculin. It is a colorless, transparent liquid, unstable in the air. It has been used by Koga (*J. Ex. M.*, 1916, xxiv, p. 107) and other Japanese physicians with asserted success in the treatment of *tuberculosis* and also of *leprosy*. Their statements concerning its composition are rather vague and the doses recommended differ widely.

Cyclamen. *Cyclamen europœum* L. *Pain de Porceau, Arthanite.* Fr. *Erdscheibe, Erdbrod, Schweinbrod,* G. *Sowbread.*—This is an herbaceous, perennial, stemless plant, of the subalpine mountainous regions of Europe. Some of the species of *Cyclamen* are among the most popular of winter plants on account of their beautiful foliage and exquisite flowers. The corm is globular, with many branched rootlets, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acridity, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity, and hence the common name "Sow Bread." The corm is a drastic cathartic, and is used to cause abortion, but has in such cases produced fatal gastro-enteritis. Its active principle appears to be *arthanitin* of Saladin, the *cyclamin* of S. De Luca. This is a poisonous glucoside, which, when boiled with diluted acids, splits into *cyclamiretin,* $C_{15}H_{22}O_2$, and glucose. It is white, amorphous, inodorous, and, when held a short time in the mouth, intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, and eventually forms a solution which froths like soap and water, and is coagulated by a heat of about 65.5° C. Its formula, according to an analysis by Klinger, is $C_{20}H_{34}O_{10}$, although Kobert (*Chem. Cb.*, 1893, i, 32) makes it one of the class of saponins, and gives it the formula $C_{20}H_{32}O_{10}$, which is the same as that of sarsaparilsaponin and smilacin. (For further details and method of preparing see *U. S. D.* 20th ed., p. 1356.) *Dose,* of powdered root, is said to be from twenty to forty grains (1.3–2.6 Gm.).

Cyclea Peltata H. and Th.—An East Indian drug, according to Sutterheim, contains an alkaloid, $C_{27}H_{31}O_4N_2$, which he named *cycleine;* it has the effect of a cardiac poison accompanied by action on the respiratory centers. (*Ph. Wb.*, 1906.)

Cycloform. *Isobutyl-para-amino-benzoate.* $C_6H_4(NH_2)COO.CH_2.CH(CH_3).CH_3$.—It occurs as white, crystalline scales, almost insoluble in water. Impens (*Ther. Geg.*, 1910, li, p. 348) asserts, however, that the saturated solution, which contains but 0.02 per cent., will produce complete anesthesia of the cornea of the eye and that even a solution of one-third this strength has a distinct anesthetic influence. According to this author, the salts of *cycloform* are more soluble, but dissociate in solution and are therefore locally irritant. Large doses produce in the lower animals drowsiness, general weakness and collapse with formation of methemaglobin.

Because of its sparing solubility cycloform has not been widely used for surgical purposes, but has received considerable commendation as a dusting powder in painful *ulcers,* especially after *burns,* and in *tuberculous laryngitis.* It appears not only to lessen the pain, but to stimulate the healing processes. Zeller (*Med. Klin.*, 1910) finds that the ointment is useful to relieve the itching of *chronic eczema* and other skin diseases as well as the pain of *anal fissure* and *hemorrhoids.* In making the ointment, Franke (*Aerzt. Rund.*, 1913) recommends that *cycloform* be dissolved in olive oil before it is incorporated with the ointment base. The dusting powder, which may be made with kaolin, should contain from 10 to 20 per cent. of cycloform. The ointment should contain from 5 to 20 per cent.

Cyclosal. *Hexeton. Homocamfin.*—This is stated to be the 3-methyl-5-isopropyl-2-cyclohexonon dissolved in a solution of sodium salicylate. The *methyl-iso-propyl-cyclohexenon,* itself, is a yellowish oily substance sparingly soluble in water. It is recommended as a circulatory and respiratory stimulant in dyspnea, heart failure, asthma, etc. It is marketed in the forms of a 1 per cent. and a 10 per cent. solution in sealed ampules.

Cydonium. *U. S.* 1880. *Quince Seed. Semen Cydoniæ. Semeneces (Pépins) de Coing,* Fr. *Quittenkerne, Quittensamen,* G. *Semi di Cotogno,* It. *Simiente de Membrillo,* Sp. *Pyrus Cydonia* L.—(*Cydonia vulgaris,* Pers.) (Fam. *Rosaceœ*), or common quince tree, has been under cultivation since very remote times. It is a native of Central Asia but grows wild in Austria, on the banks of the Danube, and is extensively cultivated for its fruit throughout the temperate regions of both continents. The fruit is a yellow pome which is covered with wooly hairs in its unripe stage. These, however, loosen and mostly fall off as the fruit matures. There are several varieties, some of which are apple-shaped, others pear-shaped. All, however, have an agreeable odor and an astringent, acidulous taste. Like the apple and pear, each fruit possesses five ripened carpels which constitute its core. Each of these contains from 6 to 15 seeds arranged in 2 rows. Though not eaten raw, it forms a very pleasant confection, and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds, which were formerly official, are ovate, angled, reddish-brown externally, white within, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope abounds in mucilage, which is extracted by boiling water. They were officially described as follows: "About 6 mm. in length, oval, or oblong, triangularly compressed, brown, covered with a whitish, mucilaginous epithelium, causing the seeds of each cell to adhere. With water the seeds swell up, and form a mucilaginous mass. The unbroken seeds have an insipid taste." *U. S.*, 1880. The seeds are used in the preparation of *bandoline* and cosmetic lotions. Two drachms of the seeds will render a pint of water thick and ropy. (*A. J. P.*, 1876, 35.) It has been proposed to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water. According to Garot, one part communicates to a thousand parts of water a semi-syrupy consistence. (*J. P. C.*, 3e sér., iii, 298.) Pereira considers the mucilage as peculiar, and proposes to call it *cydonin.* It differs from arabin in not yielding a precipitate with potassium silicate, and from bassorin and cerasin in being soluble in water both hot and cold. Tollens and Kirchner (*Ann. Ch. Phys.*, clxxv, 205–226) assign to it the formula $C_{18}H_{28}O_{14}$, regarding it as a compound of gum, $C_{12}H_{20}O_{10}$, and cellulose, $C_6H_{10}O_5$, less one molecule of water. Quince mucilage (*Mucilago Cy-*

donii, U. S., 1880) may be used for the same purposes as other mucilaginous liquids. The U. S. P., 1880, gave the following formula for its preparation. "Cydonium, *two parts;* Distilled Water, *one hundred parts.* Macerate the Cydonium for half an hour, in a covered vessel, with Distilled Water, frequently agitating. Then drain the liquid through muslin, without pressure. This preparation should be freshly made, when required for use." *U. S.,* 1880.

Cynara. *Cynara Scolymus* L. *Artichoke.*—This is a composite plant, indigenous to the south of Europe, and cultivated as a culinary vegetable. The receptacle and the lower portion of the fleshy leaflets of the flower-heads are eaten. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and variously dressed. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. *Cynara Cardunculus,* the *cardoon* of the garden, very much resembles the artichoke. The stalks of the leaves are used as a vegetable in France. Artichoke leaves have been used in *dropsies* and *rheumatic affections.* The *Jerusalem artichoke, Helianthus tuberosus* L., is another distinct plant belonging to the *Compositæ,* which has been cultivated for its edible tubers. These contain an abundance of inulin and sugar.

Cynoglossum. *Cynoglossum officinale* L. *Hound's-tongue. Langue de Chien,* Fr. *Hundszunge,* G.—A strong-scented biennial plant of the Fam. *Boraginaceæ* indigenous to Europe and naturalized in the U. S. A. Both stems and leaves of this plant are clothed with short, soft hairs. Its leaves are entire and lanceolate, sessile above, petioled below. Its stem terminates in a panicle of reddish-purple, or rarely white, funnel-shaped flowers. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odor, resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Although hound's-tongue has been believed by some to be nearly inert, there can be little doubt that it is a dangerous poison. The experiments of Diedülin (*M. S. Rep.,* 1868) many years ago demonstrated that the extract paralyzes motor nerves in vertebrate animals, and K. Greimer has found in it a poisonous alkaloid, *cynoglossine,* which acts upon the animal organism similarly to curare; also a toxic glucoside, *consolidin,* and a notable amount of choline. (*P. J.,* vol. lxv.) *Consolicin,* a derivative of consolidin, like consolidin, paralyzes the central nervous system. Cynoglossum has been used as a demulcent and sedative in *coughs, catarrh, spitting of blood, dysentery,* and *diarrhea.* The *pilulæ de cynoglosso* owe their properties chiefly to opium.

Cystopurin. $(CH_2)_6N_4.2CH_3COONa + 6H_2O$.—A compound obtained by the interaction of formaldehyde, ammonia and sodium acetate. It forms nearly tasteless, colorless, lanciform crystals which are readily soluble in water. It is recommended for the treatment of *cystitis* and *gonorrhea* in *doses* of thirty grains (2 Gm.) dissolved in water. It is also used as a prophylactic.

Cytisus. *Cytisus Laburnum* L. *Golden Chain. Golden Rain.* (Fam. *Leguminosæ.*)—Laburnum is a small hardy tree with pendent racemes of yellow flowers, native to the higher mountains of Europe. Several varieties of this tree varying in foliage and floral color are cultivated in various parts of the world. The roots taste like licorice but have poisonous properties. All parts of the plants are probably poisonous. In fifty-eight boys poisoned simultaneously by the roots, the symptoms were intense sleepiness, vomiting, convulsive movements, coma, slight frothing at the mouth, and unequally dilated pupils. (*M. T. G.,* vol. ii, 875.) In some cases the diarrhea has been severe. The convulsions have at times been markedly tetanic; wide-spread anesthesia has been noted, and also excessive mydriasis, with loss of the pupillary reflex, elevation of temperature, delirium, and cyanosis. After death there have been found erosion of the colonic mucous membrane, extreme hyperemia of the brain, and nephritis. (*D. M. W.,* xxi, 1895.) For reference to cases see *U. S. D.,* 20th ed., p. 1357.

Hausemann and Marmé isolated in 1864 an alkaloid, *cytisine,* a white, crystalline solid, of a bitter, somewhat caustic taste, soluble in water and alcohol, but scarcely at all soluble in ether, chloroform, benzene, or carbon disulphide. A second alkaloid, *laburnine,* was also announced by them. (*Chem. News,* July 16, 1869, 36.) Partheil (*A. Pharm.,* 1892, 448) has since studied cytisine, and gives it the formula $C_{11}H_{14}ON_2$. Ferric chloride colors cytisine and its salts blood-red, which color, however, disappears on diluting with water or on addition of hydrogen dioxide. If after the addition of this latter reagent the mixture is heated gently in the water bath an intense blue color is developed. When cytisine is distilled with soda lime, pyrrol is obtained, besides a base, $C_9H_{13}N$, which is possibly a hydroquinoline. A. Rannerda purified crude cytisine, obtained from the seeds of *Cytisus Laburnum* L., by the well known shaking out process with chloroform, by distilling it in a partial vacuum. Under a pressure of 2 mm. and a temperature of 228° C., the alkaloid distils over as a colorless liquid and congeals in the receiver in the form of fine crystalline needles. It separates from absolute alcohol in the form of small transparent rhombic crystals, which have the sp. gr. 1.0046 (*Ap. Ztg.,* July, 1900, 486).

According to the researches of P. C. Plugge (*A. Pharm.,* 1895), cytisine is a very widely distributed alkaloid. He has found it in eight species of the genus *Cytisus,* two of the genus *Genista,* two of the genus *Sophora,* two of the genus *Baptisia,* and in other plants. He asserts that *ulexine* of Gerrard, from *Ulex europæus* L., *sophorine* of H. C. Wood, from *Sophora secundiflora* (Cav.) DC. (*S. speciosa* Benth.), and *baptitoxine* of von Schroeder, from *Baptisia tinctoria* R. Br., are identical with cytisine. Plugge also believes that the alkaloid of *Euchestra Horsfieldii* Benn. (Fam. *Leguminosæ*), a Javanese pea, whose seeds are used as a contra-poison by the natives, is identical with cytisine. Kobert and Radziwillowicz (*Arb. d. Pharm. Inst. Dorpat.,* 1888, ii) found that cytisine caused in lower animals, spinal convulsions, followed, if the dose were large enough, by paralysis, vomiting of central origin, primary stimulation, and secondary paralysis of respiration and a marked reduction in the ozonizing powers of the red corpuscles. The blood pressure was at first elevated and later depressed and there was a paralysis of the motor nerves similar to that produced by curare. Dale and Laidlaw (*J. P. Ex. T.,* 1912, iii) find that the rise and secondary fall of the blood pressure is due to effects upon the sympathetic ganglia and that cytisine closely resembles nicotine in its physiological action. Gray (*J. P. C.*, 1862) found laburnum to produce in man narcotic effects, and commends it in *vomiting, bronchitis, whooping cough,* and *asthma.*

Of late years several salts of cytisine have made their appearance. The hydrochloride, hydrobromate and nitrate have all been used as diuretics and nervines in one-twentieth to one-tenth grain doses (0.003–0.006 Gm.).

Danais. *Danais fragrans,* Commerc. (Fam. *Rubiaceæ.*)—In this Madagascar plant, the root of which is said to be tonic and antiperiodic, Heckel and Schlagdenhauffen found a glucoside, *danain.* (*A. J. P.*, 1886.)

Daphnandra.—The bark of *Daphnandra micrantha* (Tul.) Benth., an Australian tree (Fam. *Monimiaceæ*), is asserted to be rich in poisonous alkaloid. (*P. J.*, Oct., 1887.) Bancroft states that the active alkaloid is soluble in water, and to some extent is antagonistic to strychnine.

Delpho-curarin.—Under this name an alkaloid obtained from the *Delphinium Scopulorum* A. Gray (Fam. *Ranunculaceæ*) has been placed upon the market as an amorphous white powder. It has the composition $C_{23}H_{33}O_7N$. It has been physiologically studied by Kahn (*A. I. P. T.*, 1909, p. 19) who found that it acts very similarly to curare, paralyzing the peripheral endings of the motor nerves. It has been introduced for use in the physiological laboratory as a substitute for curare, which is becoming somewhat difficult to obtain. According to Kahn, a dose of six milligrammes per kilo of body weight, given intravenously, is sufficient to completely paralyze the motor nerve of the dog. It should not be confounded with delphinine.

Dextroform is a combination of formaldehyde and dextrin, soluble in water and glycerin, but insoluble in alcohol, ether or chloroform; it occurs as a white, almost odorless and tasteless powder; it should be used with caution. It affords, according Bongartz, in from 10 to 20 per cent. solution, a useful injection in *gonorrhea* and for irrigation in half this strength.

Diafor.—This is stated to be *urea acetyl-salicylate* and is intended for use in *neuralgia* and *rheumatism.* The *dose* is 10 to 20 grains (0.6–1.2 Gm.).

Diagnostic Tests.—In addition to the Clinical Tests and Reagents described elsewhere in this volume, the following Diagnostic Tests are of importance.

Complement Fixation Tests.—While tests of this type have been proposed for several diseases, notably tuberculosis, gonorrhea and syphilis, it is only in the last named that the test has proved generally satisfactory. Insofar, also, as the principles obtain alike for all these tests, it will be sufficient here to discuss in brief only the complement fixation reaction for syphilis. This is usually referred to as the *Wassermann Reaction,* and a modified method, known as the *Noguchi Reaction.*

As mentioned elsewhere in this volume (see *Serums*) animals which have been injected with pathogenic bacteria develop certain peculiar properties in their blood. Just so the blood serum of human beings who have been accidentally infected, that is, who have acquired an infectious disease, has similar specific attributes. One of these special attributes is the power of "binding" or "fixing" complement in the presence of a suitable antigen.

Complement is the substance present in all fresh serum, which is necessary to complete certain actions of immune serum, such as the bacteriolytic action of an antibacterial serum. In the same way the serum of an animal which has been treated with red blood cells of an alien species, acting with the complement, acquires the property of destroying these corpuscles—just as if the blood cells had been bacteria—the coloring matter going out into the clear liquid. Now if the serum of a patient suffering with syphilis, for example, were brought in contact with a small amount of complement in the presence of a syphilitic antigen, the three would unite so that the complement would be no longer available for a second reaction, such as the hemolytic one. Thus we test for the presence of the syphilitic antibody by finding whether it will fix complement to itself, and we prove that the complement is fixed only by trying in vain to use it in destroying red blood cells. The antibody in the second part of the test—found in the serum of the animal which has been treated with red blood cells—is called the hemolytic amboceptor, or simply amboceptor. In the complement fixation test for syphilis, the rabbit is commonly used to produce amboceptor. The syphilitic antigen is usually not the microbe causing syphilis, but, strange to say, a heart extract whose only property in common with syphilitic material is in its chemical constitution, that is, it belongs to the class of lipoids.

To perform the test, the suspected blood serum is added to the antigen and a small amount of complement (fresh guinea-pig serum) and kept at 37° C. for an hour. The amboceptor and some red blood cells of the species used in preparing the amboceptor (usually sheep or man) are then mixed in and the five incubated together for a longer time. The tube containing the mixture is then examined and if the blood cells are still intact, forming a red opaque sediment with colorless supernatant fluid, it signifies that the complement was fixed by the first incubation, therefore the patient has syphilitic antibodies in his blood. Other tests must be carried on at the same time to prove that the amboceptor will actually hemolyze the blood cells with the given amount of complement in the presence of a non-syphilitic serum with antigen, and in the presence of the patient's serum alone without antigen. A fourth tube should be arranged to ascertain that the complement will be fixed when a known syphilitic serum is used.

It is obvious that such a reaction requiring at least seven interacting bodies to prove the presence or absence of a characteristic in one of them, is so complicated that only by repeated practice and standardization of methods can reliable data be obtained. Any of the substances concerned may be so subject to change as to have a deleterious effect on the others and destroy the value of the reaction.

It is obvious that the process briefly outlined above is much too complicated for practical demonstration in a work of this character, and in view of the newer modifications which are constantly coming into practice, the reader is referred to the following authorities: Noguchi; *Jour. Am. Med. Assn.*, 1912, lviii, 1163. Kolmer; *Infection, Immunity and Serum Therapy*, Ed. 2, Philadelphia, 1917. Craig; *The Wassermann Test,* Ed. 1, St. Louis, 1918. Boas; *The Wassermann Reaction*, Berlin, 1921.

Epinephrin Test (*Goetsch's Test for Hyperthyroidism*).—This test is conducted as follows: Eight minims of a 1:1000 solution of epinephrin (see *Liquor Epinephrinæ*) are diluted with an equal quantity of sterile water and injected hypodermically into the arm. Immediately there is formed an area of blanching around the point of injection, and about the margin of this usually a red areola gradually shading off into the surrounding tissue. In about half an hour the center of the white area becomes bluish-gray to lavender, and at the end of about one and a half to two hours the red areola takes on the bluish or lavender color, while that in the center disappears. This lavender areola remains for about four hours from the time of injection and is the most characteristic part of the test. Accompanying the local reaction may be increase in pulse rate, with palpitation of the heart and an exaggeration of the tremor and nervous symptoms in general. The test is designed to elicit evidence of hyperthyroidism. (*N. Y. State M. J.*, 18: 259, July, 1918.

Commenting upon this test the *Journal of the Amer. Med. Assn.* (1921, lxxvi, 857) states that the failure of several competent investigators to discover a strict parallelism between the changes in blood pressures and pulse rate and the degree of hyperthyroidism throws into question the diagnostic value of the epinephrin reaction in such conditions.

Tetrachlorphthalein Test for Liver Function.—In 1910 Abel and Rowntree (*J. P. Ex. T.*, i, 231) showed that phenol-tetrachlorphthalein was excreted from the blood entirely by the liver. Based on this fact Rosenthal (*J. A. M. A.*, 1922, lxxix, 2151) has devised a method for using the drug as a test of hepatic function as follows: 5 milligrammes of phenol-tetrachlorphthalein per kilogramme of body weight is injected intravenously, about 8 cc. of blood is withdrawn from a vein after 15 minutes and again in 60 minutes. This blood is allowed to clot and centrifuged and the plasma tested for the dye by adding sodium hydroxide and comparing the depth of color with a standard solution made by dissolving 10 milligrammes of phenol-tetrachlorphthalein in 100 cc. of water. In 8 cases of various indifferent diseases, including severe nephritis, he found at the end of 15 minutes from 2 to 7 per cent. of the dye in the blood and none at the end of one hour. In various diseases of the liver including carcinoma, cirrhosis, abscess of the liver, acute hepatitis, etc., he found that the elimination of the dye from the blood was very greatly prolonged, in several cases there was practically no lessening of the amount in the blood at the end of one hour, and it had not disappeared in 4 or 5 hours. He believes that the method is quantitative and gives an index of the functional capacity of the liver.

Hoxie (*J. A. M. A.*, 1924, lxxxii, 361) quotes Piersol and Bockus (*A. I. M.*, 1923) as having suggested a modification of the Rosenthal phenoltetrachlorphthalein test, the modification being based on the time of appearance of the dye in the bile entering the duodenum after intravenous injection, but Hoxie has found that this time varies so much in the same individual as to be practically useless.

*Agglutination Test for Typhoid Fever. **Widal** Test. Bass Test. Bordet Test.*

The *Widal Test* and its modifications depend upon the presence in the blood of a typhoid patient at a certain stage of the disease of substances termed agglutinins, which when brought in contact with living typhoid bacilli cause the latter to clump together and lose their motility. It is evident, therefore, that the infection must have been present a certain length of time for the Widal test to be positive, that is, until sufficient time has elapsed for the agglutinins of the typhoid germ to have been elaborated in the blood of the patient. Otherwise the test will be negative. We find, therefore, that the test is of no practical value until after the first week or so of the infection. The test is also uncertain because of the fact that the blood of many normal persons, and also persons recently inoculated with the antityphoid vaccine possesses the agglutinating property for typhoid germs. It is less marked, however, than in those infected with typhoid, and, therefore, in making the test the blood-serum is diluted to about 1 to 50, when the agglutinating power (of any but the typhoid blood) is too mild to manifest itself.

Method of Application.—The lobe of the ear having been cleaned with an antiseptic, followed by sterile water, a deep puncture is made with a sterile needle or other pointed instrument. A small amount of blood is collected either in a capillary tube or upon a sterile cover-glass. The blood or, preferably, the serum portion is diluted with normal salt solution or broth to 1 to 25, then a drop of this dilution is mixed with an equal amount of young vigorous typhoid germs from a broth culture, placed in hanging drop beneath the microscope, and observed.

Should the test be positive, in from one-half to two hours the bacilli will be seen to clump together into masses and lose their motility. The test may be made without the use of the microscope by mixing the culture and serum in a testtube, when at the end of the usual time a flocculent precipitate will be observed to form in the mixture.

A carefully heated suspension of killed typhoid bacilli (as supplied by manufacturers of biological reagents) may be used to supplant the suspension of living organisms mentioned in the above test.

Tuberculins.—Tuberculins in the broadest sense are any products of tubercle bacilli used in the treatment, prevention, or diagnosis of tuberculosis. The product to which the name was first applied is now called *Old Tuberculin* (Koch) (*Tuberculin alt, Tuberculin O. T., Concentrated Tuberculin, Crude Tuberculin*), and is prepared by growing tubercle bacilli for weeks on glycerin broth, killing the culture by steaming it for 30 minutes, and evaporating the sterilized broth to one-tenth its volume over a hot bath. The dead bacilli are then filtered out through a bacteriaproof filter and the resulting brown fluid, viscous on account of its high glycerin content and with a characteristic odor, is the tuberculin. *Koch's New Tuberculin T. R.—Tuberkelbacillen Rest, Tuberculin Residue, Tuberculin Ruckstand*—is made by triturating living tubercle bacilli, thoroughly washing in water, and grinding the insoluble residue. By alternate suspension in water, centrifuging and grinding each sediment, a series of very fine suspensions are obtained and combined. Twenty per cent. glycerin solution is added in such amount that 1 cc. of the final product represents the residue of 10 milligrammes of tubercle bacilli; this residue dried weighs about 2 milligrammes.

Tuberculin B. E. (*Bazillenemulsion* (Koch), *Bacilli Emulsion*) was Koch's final effort to find a specific for tuberculosis. This consists of ground tubercle bacilli in a 50 per cent. glycerin suspension. The coarser particles which settle in 24 hours are discarded. The dilution is such that 1 cc. contains 5 milligrammes of bacillary substance.

Tuberculin B. F. (Denys), *Bouillon Filtré, Bouillon Filtrate* is the same product as old tuberculin prepared without heating or concentration. The glycerin broth culture is simply filtered free from bacteria. A similar preparation in Germany is called T. O. A. (*Tuberkulin Original,* O. T.), or if made from bovine tubercle bacilli instead of human, P. T. O. (*Perlsucht Tuberkulin Original*).

Numerous other preparations are to be found, some very closely allied to the four above mentioned, others more variant: *Tuberculol, Tuberculin* A. F. (Albumose free), *Vacuum Tuberculin, Tuberculosis Sero-Vaccine, Tuberculin-Rosenbach, Tuberculin-Beraneck, Tubercle Bacilli Extract* (Dixon), *Suspension of Dead Tubercle Bacilli* (Dixon), *Watery Extract of Tubercle Bacilli* (von Ruck), *Tulose, Oxytuberculin* and others.

For diagnosis, old tuberculin is employed almost exclusively. It has been particularly useful in the diagnosis of tuberculosis in animals, by temperature reaction following subcutaneous injection. This method is also used in human medicine, but in any application of tuberculin, save the most external, extreme care must be used. The multitude of severe reactions and fatalities due to the use of tuberculin in the years immediately following its discovery are not to be forgotten; a dose easily borne by one individual may be highly toxic to another. Careful two-hourly temperature records should be kept for two days preceding and two days following the injection. At first not more than 0.0002 cc. may be given A safer test is the application of the tuberculin to the skin; an abrasion is made through a drop of old tuberculin on the forearm, by means of a small drill twirled between the thumb and forefinger (*von Pirquet test*). A similar abrasion is made without the tuberculin. The appearance of a papule at the former site, but not at the latter, within twenty-four to forty-eight hours, indicates the presence of tuberculosis. By this delicate test it is shown that nearly all adults have, at some time, contracted tuberculosis, even if not showing any clinical manifestations of the disease, so that the test is only applicable to children. A similar test (*Moro test*) is made by the use of a tuberculin ointment. Both of these tests are of greatest value when applied to young children. A large number of apparently healthy adults react positively to these tests, due probably to healed tuberculous processes.

Calmette and *Wolff-Eisner* have devised a conjunctival test—the tuberculin, diluted 10 times or made up to a corresponding strength with glycerin-free dried tuberculin, is dropped in the conjunctival sac. Within 24 hours, if the reaction is positive, the conjunctiva so treated becomes red and often somewhat swollen. On account of reactions which have endangered the eyesight, this test has largely been given up.

In tuberculin treatment, also very great caution should be exercised. It is customary to begin a course of treatment with 0.000,000,1 cc. hypodermically increasing gradually and not giving more than two injections per week.

Accurate records must be maintained of the patient's temperature and general condition, for only thus will the margin of safety in this dangerous product be observed. The success with any of the various tuberculins has not been remarkable, but it is asserted that in certain types of cases, some good may be accomplished. (See under *Serums.*)

Cutaneous and Ophthalmic Allergic Tests.—Some years after the discovery of the phenomenon of anaphylaxis by Richet, American observers experimenting with animals showed that anaphylactic shock induced in animals through injection of foreign proteins simulated the attacks of *hay fever* and *bronchial asthma.* According to their observations, certain persons, apparently normal, become sensitive to pollen from flowers, to animal dandruff and other animal proteins and to foodstuffs. This special sensitization may be inherited, or if acquired, may occur by virtue of defects in the mucous membranes of the nose, bronchioles or intestinal tract.

If a person, sensitive as above stated, breathes air containing pollen or animal protein or eats certain foodstuffs, a typical attack will ensue. Nor are these idiosyncrasies manifested alone in hay fever or asthma, but in many forms of skin diseases as urticaria, eczema, Quincke's edema, etc., and some authors even include migraine and epilepsy in the same group. To all of these diseases the term "Allergic diseases" is applied.

With the purpose of fixing the blame upon a specific protein, diagnostic tests may be made in the case of these *allergic diseases.* Only pollen protein extracts are used in the diagnosis of hay fever, whereas extracts of foodstuffs, and animal proteins, to an almost incredible number are used in the diagnosis of the asthmas and skin diseases. The test is conducted by scarifying, without drawing blood, the skin on the flexor surfaces of the forearm. Into each separate cut (each about an eighth inch long) is placed a small amount of the suspected protein. There is then added a drop of N/10 NaOH solution to dissolve the protein and permit of its rapid absorption. At the end of a half hour the proteins are washed off and the reactions noted, always comparing with a normal control where no protein and only the N/10 NaOH solution is used. A positive reaction consists of a raised white elevation or urticarial wheal surrounding the cut. The smallest reaction, in order to be deemed positive, must measure approximately a fifth of an inch in diameter. Small vials containing material for the application of these tests can be obtained from reliable manufacturers.

Once the diagnosis is made, treatment can be instituted to desensitize the patient by injecting gradually increasing doses of the protein, or proteins, proven by the test to be responsible for the diseased condition. It has been noted, however, that skin reactions may serve to diagnose the allergic state, but not to make a specific diagnosis.

Most recent investigators claim that the instillation of these extremely attenuated proteins upon the conjunctiva serves better as a mode of diagnosis than the cutaneous tests described above.

Dick Test for Scarlet Fever.—While there is still disagreement (1925) as to the causative factor in scarlet fever, Drs. G. and G. Dick, of Chicago, have produced a toxin by the artificial growth of diplococcus scarlatina (a streptococcus) which when injected in specific dilution into persons immune to scarlet fever, shows no reaction, whereas it produces a profound reaction in persons who are not immune to that disease. Thus can be ascertained the susceptibility of an individual to that disease. To date, the test, unlike the Schick reaction, has not been augmented by a curative, toxin antitoxin extract, although at the time of writing a serum has been advanced by Doctor Dochez of the Rockefeller Institute, which it is claimed has specific curative properties. (See under *Serums.*)

Kahn Precipitation Test for Syphilis.—A very valuable specific test and one that is much less complicated than the Wassermann and its modifications is described by Kahn (*Amer. Journ. Pub. Health,* June, 1924). It employs in the test only three ingredients, namely: antigen, serum and physiologic salt solution. The antigen is a cholesterinized beef heart alcoholic extract. Observers have agreed that this new test furnishes a simplified technic and affords results that compare favorably with the complement fixation tests.

Schick Test for Diphtheria.—In 1913, Schick published (*M. M. W.,* 1913, ix, 2608) a method by which the presence of specific antitoxin in the blood and tissue can be determined very easily. A fixed minute quantity of diphtheria toxin is injected intracutaneously and a local reaction occurs if there is less than $^1/_{30}$ of a unit of natural antitoxin per cubic centimeter of blood. This amount is considered sufficient to protect against diphtheria. The explanation of the test is that when no antitoxin is present the toxin acts on the skin; when antitoxin is present it so neutralizes the toxin that no local poisoning occurs. A negative reaction therefore indicates the presence of sufficient protective antitoxin, where a positive reaction occurs inoculation with graded doses of toxin-antitoxin mixtures (see *Antitoxinum Diphthericum*) were demonstrated by Behring to afford protection against diphtheria. This inoculation probably will eventually be as general as vaccination against small-pox.

Dial.—*Diallyl-Barbituric Acid* differs in its structure from barbital in that the two ethyl groups have been replaced by allyl groups introduced into medicine as a somnifacient. It occurs as colorless, shiny, scaly crystals, melting at 170° to 171° C.; readily soluble in alcohol and ether, and difficultly so in water. The aqueous solution gives a slightly acid reaction. It has been recommended as a somnifacient with the statements that it is superior to the allied barbital in that it does not produce unpleasant after-effects, that it requires smaller doses and that it is less toxic. These claims, however, have been brought in question by the Council on Pharmacy and Chemistry (see *J. A. M. A.,* 1920, lxxiv, 266). The dose is from one and a half to four grains (0.1–0.3 Gm.).

Diamine. *Diamidogen.—Hydrazin,* $\left.\begin{matrix}H_2N\\H_2N\end{matrix}\right\}$, is a strong base crystallizing in white crystals at 1.4° C. and boiling at 113° C.; it forms salts with the common acids. The free base mixes with water in all proportions and has a strong alkaline character and powerful reducing action. This substance has been proved by Julius Pohl to be actively poisonous. (*A. E. P. P.,* xli, 1898.)

Dianthus. *Dianthus Caryophyllus* L. *Clove Pink.* (Fam. *Caryophyllaceæ.*)—Of the ordinary garden pink those specimens should be selected for medicinal use which have the deepest red color and the most aromatic odor. The petals should not be collected until the flower is fully blown, and should be employed in the recent state. They have a fragrant odor, said to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. The syrup was formerly recognized by the Edinburgh Pharmacopœia as a vehicle.

Diaspirin. *Succinylsalicylic Acid* $(CH_2.COO.C_6H_4.COOH)_2$.—A white, odorless powder, of a somewhat acid taste, readily soluble in alcohol, sparingly soluble in water. *Diaspirin* has been used with asserted benefit in the treatment of various *rheumatic* and *neuralgic* troubles. According to Kaminer (*B. K. W.,* 1909), its value is enhanced by the fact that when given in sufficiently large doses, passing unchanged through the stomach, it not only exercises the effect of the salicylic acid, which is liberated in the intestinal tract, but that it also has a distinct diaphoretic action. Diaspirin is a dibasic acid and reacts with bases, either organic or inorganic, to form corresponding salts.

The *dose* is five to fifteen grains (0.3–1.0 Gm.) from three to six times a day.

Diazyme, Essence and Glycerole. *N. N. R.* 1924.—These are proprietary preparations which are stated to contain the starch-converting enzyme of the pancreas without the protein-converting and fat-splitting enzymes.

Dibromin. *Dibromalonyl-ureide.*—This is cream-colored crystalline solid containing 56 per cent. of bromine. It is soluble in about 33 parts of water but its solutions are not stable; the dry substance is permanent. Dibromin has a powerful germicidal action, probably due to the formation of *hypobromous acid;* it is asserted to be from 50 to 200 times as strong as phenol according to the species of bacteria against which it is tested. It has been used as a surgical disinfectant by Zeinert (*Surgical Journ.,* Nov., 1922) and others in strengths of from 1 in 1000 to 1 in 10,000 and is relatively non-toxic and non-irritant.

Dicentra.—*Dicentra pusilla* Sieb. et Zucc. is a Japanese plant belonging to the *Fumariaceæ* which is used in that country as a folk remedy in dysentery. Asahina (*A. Pharm.,* 1909, ccxlvii) has found it in an alkaloid, $C_{20}H_{21}NO_4$, which is isomeric with papaverine. It has been studied physiologically by K. Iwakawa (*A. E. P. P.,* 1911, lxiv), who finds that it produces in both cold and warm blooded animals a light narcosis, followed, if the dose be large, by convulsions. It also caused a fall in the blood pressure with slowing of the heart and depression of the respiratory center.

Dichlorbenzol. *Para-dichlorbenzene* 1–4, $C_6H_4Cl_2$.—It occurs in colorless crystals and is used as an insecticide. It is said that the vapors are penetrating and kill insects, larvæ and eggs. It is used to combat peach borers by fruit growers.

Dichondra Brevifolia.—An extract of this plant dissolved in glycerin is used as an application in the treatment of *diphtheritic ulcers.* It is applied direct to the mucous membrane and is claimed to possess specific action on the diphtheritic bacilli.

Dichlorethylene.—This is a non-combustible liquid with a specific gravity of 1.29 and a boiling point of 55° C. It has been suggested by Wittgenstein (*A. E. P. P.,* 1918, lxxxiii, 235) as a general anesthetic. He asserts that it exercises no injurious effect upon the circulation. While it has not been used to any large extent in human beings, there have been noticed during the narcosis undesirable muscle contractions; it is asserted, however, that these can be controlled by the use of morphine.

Didymium is now recognized generally as a mixture of *neodymium* and *praseodymium*, freed as far as possible from lanthanum, the salts of the neodymium being in general rose-colored, while those of the praseodymium are of a greenish-yellow. The by-products obtained in the manufacture of gas mantles and certain other chemical manufactures have been utilized in making the salts.

Didymium Chloride. Didymii Chloridum. $Di_2Cl_6 + 12H_2O$.—This salt has been used in the form of a rose-red, odorless and non-irritant solution containing 25 per cent. to 30 per cent. of the salts. It has been affirmed that the chloride is superior to phenol as a germicide, but the experiments of I. Schmidt and of Pflücker (*M. R.*, 1898, 1900) show that it is much inferior, a 5 per cent. solution being required to destroy ordinary germs.

Didymium Nitrate, Didymii Nitras, $Di_2(NO_3)_6.12H_2O$, occurs in rose-colored crystals soluble in water and alcohol. Antiseptic in solution of the strength of 1 in 2000. (*Cb. B.*, xxi.)

Didymium Salicylate. Dymal.—A very fine pinkish powder free from odor. It has been specially recommended by Kopp, Roth, and others as an innocuous, non-irritant, desiccant, and antiseptic dusting powder in various skin diseases, especially in weeping *eczema*, and also *hyperidrosis*, and *burns* of the first and second degree. In *erysipelas* and drier forms of skin disease it failed to be of service. It is especially popular with the veterinarians because of its relatively low cost.

Didymium Sulphate. Didymii Sulphas. $Di_2(SO_4)_3 + 6H_2O$.—This salt has been marketed in the form of a pale rose-red powder to be used for disinfecting closets, etc.

Diervilla. *Diervilla Lonicera* Mill. (*D. trifida* Moench.) *Bush Honeysuckle.*—A low, erect, indigenous shrub belonging to the *Caprifoliaceæ* and found growing in dry woods and rocky places throughout the Eastern Northern States and Canada. The whole plant is supposed to be possessed of diuretic and astringent properties, and is given in infusion by the eclectics in diseases of the urinary passages. L. E. Dawson (*Chem. News*, 1912) examined the fruit of *D. Florida.* The dark-red berries contain fructose, fixed oil, tartaric and citric acids and an alkaloid which he believes to be *narceine.* Charvaux found a glucoside identical with *fraxin* in *D. lutea.* (*J. P. C.*, 1911, 248.)

Diethylketone.—*Propione,* $C_2H_5.CO.C_2H_5$, is obtained by the dry distillation of *calcium propionate* $(C_3H_5O_2)_2Ca$. A transparent liquid, soluble in twenty-four parts of water, mixing with water, alcohol, and ether, boiling at 101° C.; recommended by Albanese and Barabini in 1892, as inducing sleep in animals. It has been used by Giovanni in the treatment of *maniacal* and *hysterical excitement* in *doses* of from eight to twenty grains (0.5–1.3 Gm.). It should be administered in dilute solution.

Digalen.—Under the name of *digalen* there has been introduced into medicine a solution which is asserted to contain *soluble digitoxin.* There is no doubt that this preparation contains a principle which exercises a digitalis effect upon the heart, but that this principle is identical with digitoxin is improbable. The claim for the application of the term digitoxin is based upon the fact that it has the same empirical formula as this glucoside, but since it would appear that its molecular weight is only half of that of crystalline digitoxin it is more probable that it is a polymer of this body. According to Kiliani (*A. J. P.*, 1913, lxxxv, 224), it is identical with digitalein.

Digalen has been used to a large extent in the treatment of chronic cardiac conditions for precisely those cases in which digitalis is useful. It has been used by the mouth and by intramuscular and intravenous injections. Although it appears to be less irritant to the body tissues when injected intramuscularly than are most of the other digitalis preparations, this method of administration is not entirely painless. The *dose* of the remedy is from fifteen to twenty minims (0.9–1.3 Gm.).

Diiodacetylene, C_2I_2, is made simultaneously with *tetraiodoethylene,* C_2I_4, (*Diiodoform, Ethylene Periodide*), by the action of a solution of iodine in potassium iodide upon calcium carbide. The two are separated by reason of their different solubilities. Tetraiodoethylene is in the form of bright yellow, odorless, needle-like crystals, insoluble in water, only slightly soluble in alcohol but readily soluble in chloroform. It contains 95.3 per cent. of iodine and is recommended in the place of iodoform. It is decomposed by exposure to light. Diiodacetylene has been found by E. Mebert (*A. E. P. P.*, xli, 1898) to be very actively poisonous.

Dimazon. *Diacetylaminoazotoluene.* $CH_3.C_6H_4.N:N.C_6H_3(CH_3)N(CH_3CO)_2$. *N. N. R.* 1924.—This is recommended for the purpose of stimulating epitheliazation over old *ulcers, wounds,* etc. It is asserted to have the advantage over similar preparations that it does not stain. It is used as a 2 per cent. ointment either made with petrolatum or a fatty oil or as a 5 per cent. dusting powder.

Dimethylaminoazobenzene. *Butter Yellow,* $C_6H_5N:N.C_6H_4N(CH_3)_2$.—"It forms yellow plates melting between 115° and 117° C. (239° and 242.6° F.). It is insoluble in water, soluble in alcohol; soluble in hydrochloric acid with a red color from which solution sodium hydroxide T.S. in excess precipitates the orange-yellow base. The solution of this dye in sulphuric acid is yellow and changes to red on dilution with water." *U. S. IX.*

It is used as a test in examining the gastric secretions (see *Diagnostic Reagents*).

Dimethyl Sulphate, $(CH_3)_2SO_4$, is a liquid boiling at 188° C., soluble in alcohol and ether. This substance has come into importance with toxicologists on account of the number of fatal cases of poisoning occurring from it, due to its extended use in chemical factories. It acts locally as a strong caustic and also influences the central nervous system, producing nystagmus, convulsions, and respiratory death during coma. (See S. Weber, *A. E. P. P.*, Bd. xlvii.)

Dinitrocresol. $C_6H_2(NO_2)_2\left\{\begin{matrix}CH_3\\OH\end{matrix}\right.$.—This is a coal tar dye, commercially called *Saffron Substitute* and is a mixture of the potassium salts of dinitro-ortho- and para-cresols. It is said to have been sold for saffron in Berlin, with fatal results. (*Ph. Rund.*, Prague, 1887.)

Dioform. *Acetylene Dichloride.* $CHCl = CHCl$.

—This occurs as a colorless fluid with an odor somewhat like that of chloroform. Sp. gr. 1.29, melting point, 55° C. Villinger (*A. K. C.*, 1907) found that it produced a narcosis with abolition of reflexes without changes in the circulation or in the kidneys. He also employed it as an anesthetic for human beings in doses of from two hundred and fifty to three hundred and fifty grains (15–24 Gm.) and found that it produced a condition suitable for surgical operation in three to five minutes with very slight stage of excitation. It has not been used, however, sufficiently to justify any conclusions as to its practical therapeutic value.

Diogenal. *Dibrompropyl-diethylbarbituric Acid.* $C_{11}H_{16}O_3N_2Br_2$.—This is a white, crystalline powder, almost insoluble in water, but soluble in alkaline solution and alcohol. It is used as a somnifacient and general nerve sedative. According to Heinz (*M. M. W.*, 1913, p. 2618), it is only about one-fourth as toxic as barbital. The *dose* is ten to thirty grains (0.65–2 Gm.).

Dioscorea.—According to Kobert the *Dioscorea Tokoro* contains an extremely toxic saponin, *dioscin.* This is so powerful that one part in 400,000 is sufficient to cause hemolysis. Honda (*A. E. P. P.*, 1904, li, 213) has found in it other saponins. For account of other species of *Dioscorea* see Part 1.

Diospyros. *Persimmon. Date-plum. Possumwood. Fruits de Plaqueminier de Virginie,* Fr. *Persimmonfrüchte, Dattelpflaumen,* G.—*Diospyros virginiana* L., or persimmon (Fam. *Ebenaceæ*), is a small indigenous tree, occurring in woods and old fields from Connecticut to Florida and west to Iowa and Texas. It possesses alternate, simple, oval, entire margined, dark-green leaves and rough bark which is often broken up into quadrangular blocks and cinnamon-red at the base of the fissures. Its greenish-yellow flowers appear about May or June. Its fruit is a spherical, orange-colored, often red-cheeked, 4–8 seeded berry which is surrounded at the base by a thick, 4-parted calyx.

The bark of the persimmon was official in the Secondary List of the first, second and third editions of the *U. S. P.*, while the unripe fruit appeared in the Secondary List of the fourth, fifth and sixth editions. The bark is astringent and very bitter.

While green, the fruit is excessively astringent, but, when perfectly mature, and after being touched by the frost, it is sweet and palatable. The unripe fruit, according to B. R. Smith, contains tannic acid, pectin, sugar, malic acid, coloring matter, and lignin, (*A. J. P.*, xviii, 167.) The persimmon has been used by Mettauer in *diarrhea, chronic dysentery,* and *uterine hemorrhage.* The *dose* of the vinous tincture (an ounce of the fresh green fruit to two fluidounces of dilute alcohol) is half a fluidounce (15 cc.) or more. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1474.

Diplosal. *Salysal. Salicylo-salicylic acid. Salicyl Salicylate. Salicylic Ester of Salicylic Acid.* $OH.C_6H_4.COO.C_6H_4.COOH$.—On decomposition in the human organism, two molecules of salicylic acid are formed, water being taken up, so that 107 parts of salicylic acid are formed from 100 parts of the ester. It is a white, crystalline powder, insoluble in water.

Diplosal owes its therapeutic virtues to its decomposition in the intestines and the liberation of salicylic acid. Its range of usefulness is precisely similar to that of the other salicylates over which, however, it has the advantage that because of its insolubility in dilute acids it is much less prone to disturb the stomach. It appears, however, to be decomposed in the intestines with comparative slowness, so that its action is less prompt than that of other salicylates and correspondingly more persistent. It has been used by Strauch (*Th. M.*, 1909), Minkowski (*Ther. Geg.*, 1908) and others with success in the treatment of both *acute* and *chronic rheumatism.*

The *dose* is eight to ten grains (0.5–0.7 Gm.) repeated, if necessary, up to a daily maximum of ninety grains (6 Gm.).

Dipropæsin.—A condensation product of 2 molecules of propæsin, $CO.(NH.C_6H_4.COOC_3H_7)_2$. It is a white powder, insoluble in water, soluble in alcohol; melting point, 171°–172° C. It is used as a local anesthetic. Kluger (*Th. M.*, 1909) suggested its employment as a local anesthetic in intestinal conditions, on the theory that its action is only made manifest in the presence of alkaline media and would, therefore, be limited when given by the mouth, to the intestinal tract. The clinical reports, however, are too scanty to justify any conclusion as to its value. The *dose* recommended is eight grains (0.5 Gm.).

Dirca. *Dirca palustris* L. *Leatherwood. Moosewood. Wicopy.* (Fam. *Thymelæaceæ.*)—A shrub growing widely in the Northeastern United States and Canada. The bark is very tough and was formerly used by the Indians for thongs. The wood is soft, white and brittle. The drupes, which are small, ovoid, and of an orange or reddish color, are said to be narcotic and poisonous. The tough bark, in the fresh state, has a peculiar, rather nauseous odor, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acridity completely to alcohol, but imperfectly to water even by decoction. Six or eight grains of the fresh bark produce violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it slowly excites redness and ultimately vesicates. Lecours reports that this shrub, growing abundantly in Canada, possesses strongly purgative properties. When extracted with 90 per cent. alcohol, an extract on evaporation is obtained which produces a laxative action in doses of 0.3 Gm. The extract contains a small amount of a volatile oil, some fixed oil and a resinous substance, the latter occurring in the form of a soft oleoresin producing a strong laxative effect when administered in doses of 0.05 Gm. (*Chem. and Drug.*, 99, 443.) It is analogous to mezereon in its medicinal characters.

Dolomol.—A white insoluble powder, nearly inodorous and tasteless, consisting mainly of *magnesium stearate* with small amounts of magnesium oleate and palmitate. It is used as a dusting powder in affections of the skin, either alone or in combination with various other remedies.

Doundaké. *Dundaki. Quinquina Africaine. Kina du Rio Nunez.*—*Sarcocephalus esculentus* Afzel (Fam. *Rubiaceæ*) of Africa yields a bark which is said to be an astringent and tonic febrifuge. For a description of the bark and its chemical characteristics, see *P. J.*, vol. xvi, 49. Heckel and Schlagdenhauffen attribute its power to three resinous principles, the first of which is of an orange-yellow color and very bitter, soluble in water, alcohol, and potassium hydroxide; the second light yellow in color, soluble in potassium hydroxide but not in water; the third soluble in potassium hydroxide, insoluble in water or alcohol. (*J. Soc. Chem. Ind.*, 1886, 435.)

The wood of the *Sarcocephalus Diderrichii*, which is used for making shuttles, has been found by Gibson to contain an alkaloid, which is a cumulative cardiac poison. Workers in the wood frequently suffer and even die from cardiac disturbances. (*Bio-Chem. J.*, 1906, i, p. 39).

Dracontium. *Symplocarpus Fœtidus* (L.) Nutt. (*Spathyema fœtida* (L.) Raf. *Dracontium fœtidum* L. *Ictodes fœtidus* Bigelow.) *Skunk Cabbage. Skunk Weed. Polecat Weed. Racine de Pothos fétide*, Fr. *Stinkende Drachenwurzel*, G.—A perennial herb belonging to the *Araceæ* and indigenous to wet places from Nova Scotia to South Carolina west to Minnesota and Iowa. Its spadix, enveloped by a broad spathe beautifully mottled with purple and yellowish-green spots and stripes appears as early as late January in the middle states. The large ovate-cordate leaves appear later. All parts of it have a fetid odor, dependent upon an extremely volatile principle, which is rapidly dissipated by heat. The rhizome should be collected in the autumn, or in the early spring.

The rhizome and roots of Skunk Cabbage have occasionally been found in lots of Veratrum Viride due to the carelessness of collectors. Both of these plants frequently grow together in the same locality.

The rhizome occurs either whole or in transverse slices. When entire, it is cylindrical or in the shape of a truncated cone, 5 to 10 cm. long and 2 to 4 cm. thick, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The rootlets are of various lengths, 2 to 4 mm. thick, coarse, simple, and very strong, very much flattened and wrinkled, white within, and covered by a yellowish or reddish-brown epidermis, considerably lighter colored than the body of the rhizome. The odor is fetid, the taste acrid; both are lessened by drying and progressively diminish with time, so that the dried rhizome should not be kept longer than a single season. This acridity is entirely absent in the decoction. The seeds are very acrid, and, though inodorous when whole, give out, when bruised, the peculiar odor of the plant.

The rhizome is affirmed to be antispasmodic and narcotic; occasioning nausea and vomiting, with headache, vertigo, and dimness of vision. It has been used with alleged success in *asthma, chorea, hysteria*, and *whooping cough. Dose*, of powder, from ten to twenty grains (0.65–1.3 Gm.), increased *pro re nata.*

Dragon's Blood. *Sanguis Draconis. Sang-dragon*, Fr. *Drachenblut*, G. *Sangre de drago*, Sp.—The term dragon's blood has been applied in a number of resinous substances which appear to have nothing in common except a red color. According to Sollmann (*J. A. Ph. A.*, 1920, ix, 141) the term was applied up until the sixteenth century to the exudates from *Dracæna sinnabari* (*African dragon's blood*) and to *D. draco* (*Canary dragon's blood*). Neither of these at present appear in commerce to any extent. The West Indian dragon's blood is derived from the *Pterocarpus draco.* At present the term is usually applied to an exudate from the surface of the fruits of a number of palms and may be designated as "East Indian dragon's blood." Of these there are several commercial varieties, obtained from a number of species of *Dæmonorops*, a genus which was previously ascribed to *Calamus.* Malay dragon's blood is obtained from *Dæmonorops didynophyllos, D. micranthus* and *D. propinquus;* Sumatra dragon's blood from *Dæmonorops Draco* Blume (*Calamus Draco* Willd.). In Borneo a dragon's blood is obtained from *Dæmonorops draconcellus* and other species of *Dæmonorops.* On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapor of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small oval masses (*tear dragon's blood*) of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected in a row like beads in a necklace; sometimes in cylindrical sticks, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. See paper by E. M. Holmes in *P. J.*, 1905, 933.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90.7 parts of a red resin, which he calls *draconin*, 2.0 of fixed oil, 3.0 of benzoic acid, 1.6 of calcium oxalate, and 3.7 of calcium phosphate. Tschirch (*Harze und Harzbehälter*, 1900, p. 189) has made an elaborate study of dragon's blood, and finds 2.5 per cent. of *draco-alban*, $C_{20}H_4O_4$, a white substance melting with decomposition at about 200° C.; 13.58 per cent. of *draco resen*, a yellow resinous substance of the formula $C_{26}H_{44}O_2$, and 56.86 per cent. of *draco resin*, a resin ester or mixture of esters, *benzoic dracoresinotannol ester* and *benzoylaceticdracoresinotannol ester*, and 18.4 per cent. of insoluble substances. It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart color to various pharmaceutical preparations. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1475.

Duboisia.—*D. myoporoides* R. Br. (Fam. *Solanaceæ*) is a tall, glabrous shrub or small tree, which is a native of Australia, New South Wales, New Caledonia, and Queensland. The alkaloid *duboisine* was discovered in the leaves by A. W. Gerrard. (*P. J.*, viii, 787). For his method, see 16th ed., *U. S. D.;* also, for an account of the chemical and medicinal properties of this alkaloid, and its relations to atropine, see *Belladonna.*

According to the researches of Jos. Lanterer (*L. L.*, 1896), the old leaves and twigs of *Duboisia myoporoides*, contain hyoscyamine, the fresh young leaves scopolamine, the dried leaves being stronger than are belladonna leaves, and yielding 0.97 per cent. of alkaloid. *Duboisia Leichhardtii* F. v. Muell. is said to be still richer in alkaloid, which is chiefly amorphous scopolamine; while the leaves of *Datura arborea* L. (*Brugmansia arborea* Steud.) and of *D. cornigera* Hooker (*Brugmansia Knightii* Hort.), natives of South America, acclimatized in Queensland, contain a mixture of hyoscyamine and atropine.

Duboisia Hopwoodii F. v. Muell., *pitury plant*, is the source of *pituri*, a narcotic stimulant largely used by the natives of Central Australia. The drug itself is a fine powder, composed of the leaves and twigs which are gathered during the month of August, while the flower is in bloom, and are put up in various forms of circular mats about 7.5 cm. in diameter. The natives smoke and chew pituri, and it is alleged to have a powerfully stimulating effect, assuaging hunger, and enabling those who are its devotees to perform much labor and go long journeys with but little food. Pituri contains from one to two per cent. of a liquid, acrid alkaloid, *piturine*, $C_{12}H_{16}N_2$, the identity of which with nicotine, although denied by Liversidge (*Proc. Roy. Soc. N. S. W.*, 1880), has been reaffirmed by Rothera (*A. J. P.*, 1918, xc, 34).

Eckaine. — N - Benzoylhydroxypropylnorecgonidine ester. This cocaine substitute is a crystalline base, giving a water-soluble hydrochloride which in neutral solution can be sterilized at 100° C. without decomposition. According to W. Wichura it is only slightly toxic, acts on the respiratory center similarly to cocaine but to a lesser degree, and is a powerful local anesthetic. It causes at first a lowering, often followed by an increase, of the blood pressure. The anesthetic action of other noregonidine derivatives such as *hydroeckaine*, or the corresponding hydroxyethyl and hydroxyamyl compounds, is much weaker than that of eckaine. (*J. Soc. Chem. Ind.*, 1919, xxxviii, 598.)

Elastica. *U. S. VIII* (*Br.*, 1889). *Rubber. Caoutchouc*, Br. *India-Rubber. Resina Elastica, Gummi Elasticum. Caoutchouc*, Fr. Cod. *Kautschuk. Federharz*, G. *Caucho, Cahuchu, Goma elastica*, Sp.—" The prepared milk-juice of several species of *Hevea* Aublet. (Fam. *Euphorbiaceæ*), known in commerce as Para Rubber." *U. S. VIII.* " The prepared milk-juice of Hevea brasiliensis, *Muell. Arg.*, and probably other species; known in commerce as pure Para rubber." *Br.*, 1898.

Rubber was made official in the U. S. P., 1890, because of its use in making mustard paper, and in the Eighth Revision it was used in the formula for belladonna plaster.

Rubber is a mixture of several substances occurring in the coagulated latex or milk-juice of certain tropical plants. It is chiefly composed of caoutchouc, a soft, solid, elastic hydrocarbon. The milk-juice occurs rather in laticiferous vessels which form an anastomosing network, or in latex cells which occur as isolated tubes. Both of these latex-storing devices occur in the middle and inner bark of many stems and roots as well as in the soft parenchymatous regions of numerous leaves, flowers and fruits. Latex is believed by the vast majority of naturalists to be a waste product. It is undoubtedly present as a means of defending plants which possess it against attacks of browsing animals. The yield of pure rubber from the latex varies from 20 to 60 per cent.

The world's supply of rubber to-day is obtained from wild and cultivated plants (India-rubber) as well as prepared synthetically (synthetic rubber). The latex employed in the preparation of India-rubber is collected from plants most of which are trees, shrubs and vines growing chiefly in South America, Mexico, Central America, West Indies, India, Ceylon, the Federated Malay States, East Indies and Africa. Nearly 100 species are known to contain latex from which rubber can be prepared. These are distributed for the greater part in four families, viz.: *Euphorbiaceæ, Apocynaceæ, Moraceæ* and *Asclepiadaceæ.*

The rubber-producing *Euphorbiaceæ* are chiefly members of the genera *Hevea* and *Manihot*, trees, indigenous to Northern South America. *Hevea brasiliensis* and other species of *Hevea* furnish the Pará rubber while *Manihot glaziovii* and allied species furnish the Ceará or Manicoba rubber.

The rubber-producing *Apocynaceæ* are chiefly members of the genera *Landolphia* of West Africa and Madagascar, *Willoughbeia* of India and Australia, *Vahea* of South America, Madagascar and Africa, *Hancornia* of Brazil, *Urceola* of the Malay States and East Indies, *Forsteronia* of Guiana and Jamaica and *Funtumia* of West and Central Africa. The Landolphia species are huge woody vines which yield most of the African rubber. *Willoughbeia firma* yields Borneo rubber. *Hancornia speciosa* is the source of Mangabeira rubber while Penang rubber is the product of species of *Urceola. Funtumia elastica* is the chief source of West African rubber.

The rubber-producing *Moraceæ* are scattered through tropical countries and are chiefly represented by the genera *Castilloa* and *Ficus. Castilloa elastica* and allied species of *Castilloa*, large trees inhabiting Northern South America, Central America, Mexico and the West Indies yield Central American rubber. *Castilloa ulei*, a tree of Peru, yields Cancho rubber. The *Ficus elastica*, native to Southern Asia and the East Indies, is now the chief source of East India rubber. This rubber is collected in Java, Rangoon and Penang.

The cultivation of rubber-producing trees and vines dates back to 1860 when the British government introduced seedlings of *Hevea* into Assam. Successful plantations were established of *Manihot glaziovii* in Ceylon and of *Ficus elastica* and *Castilloa elastica* in the Federated Malay States by British interests. Thousands of acres of *Castilloa elastica* were planted by American interests in Mexico and Central America. All of these species under cultivation yielded an abundance of rubber but could only be tapped at intervals of several months. After some experiments *Hevea brasiliensis* showed that it could be tapped daily and that the year's product from this species surpassed that of all of the other species grown, the cultivation of most of the other rubber plants was abandoned and this species introduced wherever possible to grow it. It is now being successfully grown on plantations in Ceylon, Straits Settlements, Malay States, Burma, the East Indies, Africa and Australia. It is the chief botanical source, to-day, of both plantation and wild rubber.

Of the numerous commercial varieties of crude rubber, that known as " Fine Para " represents the standard of the manufacturer of rubber articles. There are several grades of this variety, the most esteemed being known as " Suarez, Beni Bolivian," a product of trees of *Hevea brasiliensis* which thrive along the upper Amazon river.

Pará rubber is collected from wild plants of the genus *Hevea* growing chiefly in Brazil. It is gathered from June to February by the natives who make small vertical incisions with a machete in each tree to be tapped about six feet from the ground. Below each cut a tin-cup is hung on the tree to catch the milky juice as it flows from the wound. The collector pours the contents of each cup into a large vessel which is carried to his hut. Here a fire is built which furnishes a dense smoke. He takes a wooden paddle, holds it over the smoke, then dips it into the latex, again holding it over the smoke and revolving it slowly, repeating the dipping and rolling maneuver until a " bolacho," or " ham " weighing 50 to 60 pounds is formed. Each bolacho consists of several layers blackened on the surface by oxidation. These are sent down the Amazon by boat to Pará and Rio de Janeiro and boxed for shipment to various parts of the world.

The method of collecting cultivated rubber and preparing it for the market is more scientific than that employed by the natives of South America. In tapping the trees either the herring-bone or the spiral systems are usually employed. In the herring-bone system, vertical channels are cut in the bark with lateral connecting channels about one foot apart at an angle of 45°, the milk-juice being collected in cups at the base of the vertical channels. In the spiral system, a series of spiral grooves are cut around the trunk. The latex is transferred from the cups to rectangular tanks or casks and coagulated by acetic acid. It is then washed, and generally cut up into small pieces which are passed through grooved rollers of a machine coming out as ribbons or "crepe" which are dried. Occasionally the latex is coagulated in shallow dishes and the rubber is then obtained in a block or cake of similar shape to the dish. This is known as "biscuit rubber." The plantation or cultivated rubber is much lighter in color than that coming from South America on account of not being subjected to the natural process of oxidation. The "crepe" variety occurs in sheets of a beautiful amber color. The discovery of a method of preserving the uncoagulated latex has led to its utilization, and shipments of preserved latex are constantly increasing.

The total world's production of wild and plantation rubber in 1922 was 379,920 long tons. Of this amount 354,980 tons represented plantation rubber from Southeastern Asia and neighboring islands.

Synthetic Rubber.—For many years attempts have been made to make rubber substitutes by the vulcanization of fatty oils with either sulphur or sulphur chloride. Linseed oil, cotton seed oil, and the fish oils have all been used for this purpose with varying success. Very successful results have been obtained by the vulcanization of maize oil. These products, known in Germany as *Factis*, may be white or dark colored, the latter color being obtained by the prolonged action of the sulphur. Oxidized or blown oils and sulphonated oils are also used for the vulcanization. In 1894 Nobel patented solutions of nitrocellulose in heavy oil solvents as rubber substitutes for rubber varnishes and coatings. Much reclaimed rubber from old rubber articles is revulcanized and incorporated with pure rubber in the manufacture of new rubber articles. Synthetic caoutchouc, comparable in all respects, both chemically and physically with the natural product, has lately been produced by the polymerization of the hydrocarbon butadiene, C_4H_6, isoprene, C_5H_8, and dipropylene, C_6H_{10}. As isoprene is prepared from amyl alcohol or fusel oil its success commercially depends largely upon the cost of the amyl alcohol.

Properties.—Pará rubber occurs in rounded, cylindrical or flattened masses externally brownish-black and internally of numerous layers of yellowish color separated by dark lines. It possesses a characteristic odor. It contains 40 to 60 per cent. of caoutchouc. Plantation or Ceylon rubber occurs in large thin sheets of an amber or rarely brownish-black color or in yellowish-brown or dark-brown blocks. Rubber was officially described as "in flask-shaped or roundish masses, or in pieces of the same having sharply incised surfaces and exhibiting a laminated structure; floating on water; externally brownish to brownish-black; internally of a lighter tint, mottled; odor creosote-like; nearly tasteless. Pure Para rubber is insoluble in water, dilute acids, or dilute solutions of the alkalies; soluble in chlorofrom, carbon disulphide, oil of turpentine, petroleum benzin, and benzene; when heated to about 125° C. it melts, remaining soft and adhesive after cooling." *U. S. VIII.* "In elastic masses of varying thickness, brownish-black externally and mottled with a pale tint internally; insoluble in water, ethyl alcohol, alkaline solutions, or dilute acids, soluble in chloroform, oil of turpentine, carbon bisulphide. benzol, and petroleum spirit. When heated to about 257° F. it melts, remaining soft and adhesive after cooling. Odor characteristic, somewhat empyreumatic; nearly tasteless." *Br.*, 1898.

Chemical Constitution.—The juice of the rubber trees, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown color, while the mass remains white or yellowish-white within. It is said that a little alum facilitates the coagulation, while ammonia retards it, so that a little of the latter may be advantageously added, when it is desired to keep the milky juice in the liquid state. The recent juice contains, according to Faraday, 1.9 per cent. of vegetable albumen, traces of wax, 7.13 per cent. of a bitter nitrogenous substance soluble in water and alcohol, 2.9 of a substance soluble in water but insoluble in alcohol, 56.37 soluble in water with a little free acid, and only 31.7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles, the concrete juice, as it reaches us, generally contains soot, derived from the smoke used in drying it. *Pure caoutchouc*, or rubber, is nearly colorless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and odor, fusible at about 120° C., remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in chloroform and most of the fixed and volatile oils, though, in the latter, at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras, dissolve it without change, and that when precipitated by alcohol from its solution in oil of cajuput it is still elastic. But its best solvents, for practical purposes, are petroleum benzin, the empyreumatic oil obtained by distilling caoutchouc itself, carbon disulphide, and pure oil of turpentine. According to Bolley, the best method of effecting its solution, for the preparation of a varnish, is first to digest it, cut in small pieces, in carbon disulphide, which converts it into a jelly, and then to treat this jelly with petroleum benzin. A larger proportion is thus taken up than by any other method. Rubber is not immediately affected by atmospheric air, chlorine, hydrochloric or sulphurous acid gas, or ammonia. Rubber articles usually undergo deterioration upon keeping from oxidation. This may be retarded by storing them in the dark protected from extremes of temperature. Pressure and contact should also be avoided. It is stated that a small amount of naphthalene placed in a confined space with rubber articles will act as a preservative of their elasticity.

Rubber chemically is composed of a mixture of polyterpenes. When destructively distilled, it yields *isoprene*, C_5H_8, and *dipentene*, $C_{10}H_{16}$. When isoprene is treated with concentrated hydrochloric acid, it is polymerized, and a substance obtained which resembles caoutchouc and is probably identical with it. When rubber is vulcanized, it may contain from 2 to 20 per cent, of sulphur, of which, however, not more than the lower amount is chemically combined, the rest being held mechanically, and capable of removal by treatment with caustic alkalies. By the action of sulphur, rubber acquires properties which greatly increase its value in the arts. It either becomes pliable, soft, and tough, or if the amount of sulphur be increased, of a horny consistence, but preserves its elasticity under the influence of moderate heat or cold, is compressible with great difficulty, and resists the ordinary solvents such as petroleum and oil of turpentine. In this state it is said to be vulcanized. The discovery of the process of *vulcanization* is ascribed to Charles Goodyear, of New York. (*Chem. Gaz.*, x, 193.) It consists in submitting rubber in thin sheets to the action of a mixture composed of 40 parts of carbon disulphide and 1 of sulphur chloride. For fuller details the reader is referred to the *J. P. C.* (3e sér., xvii, 205.) The same object may be effected by other methods. When thin layers of rubber are immersed for two or three hours in melted sulphur at the heat of 116° C., they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of from 135° C. to 160° C., a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the rubber be first pounded with from 12 to 20 per cent. of finely powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case a portion of uncombined sulphur remains mechanically mixed with the vulcanized rubber, from which it may be separated by various solvents, such as solutions of potassium or sodium hydroxide, carbon disulphide, oil of turpentine, anhydrous ether, etc. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. For details of these two processes—viz., vulcanization by heat with sulphur or metallic sulphides, and cold vulcanization with solutions of sulphur chloride—see Sadtler's *Industrial Organic Chemistry.*

Rubber is so insoluble that it cannot be absorbed in any form into the blood and it is therefore physiologically inert when taken internally. It is used enormously in the arts for an infinite variety of purposes. In medicine it is used as the basis of various adhesive plasters as well as for numerous mechanical purposes.

Egols.—This name has been applied by E. Gautrelet (*C. R. A. S.*, 1899, 11) to a series of substances introduced by him. They are *o-nitroparasulphonates* of phenol, cresol, and thymol, in chemical combination with mercury and potassium. The *egols* are permanent compounds which crystallize with difficulty in rhombohedra, but which occur in commerce as reddish-brown powders, freely soluble in water, forming odorless and tasteless solutions, neutral in reaction, and free from caustic or irritant character. In solutions of 0.4 per cent. they are said to be actively inhibitory to the growth of germs, and in stronger solutions powerfully bactericidal. It is claimed for them also that they are not poisonous to man, although when given in overdoses they sometimes act as an emetic.

Eikonogen.—The sodium salt of amidobetanaphthol-betamonosulphonic acid, $NH_2C_{10}H_5(OH).SO_3Na + 2\frac{1}{2}H_2O$. This is a white powder having a strong reducing action on silver salts. It is soluble in water and is used as a photographic developer. It has also been used in the treatment of *ivy poisoning.* It is decomposed by contact with fumes of ammonia.

Elarson. *Arsoben.*—Under this name *strontium-chlorarsenobehenolate* has been introduced. It is a nearly white, tasteless powder insoluble in water and sparingly soluble in alcohol or ether, and represents about 13 per cent. of arsenium. Its range of usefulness is precisely that of arsenous oxide. The beginning *dose* is about one one-hundredth of a grain (0.0006 Gm.) three times a day, which may gradually be increased up to one-twentieth of a grain (0.003 Gm.) three times a day or more.

Elaterium. *Br.* 1898. *Extractum Elaterii. Elaterium, Elaterion,* Fr. *Elaterium,* G. *Elaterio,* It., Sp.—"A sediment from the juice of the fruit of Ecballium Elaterium, *A. Richard.*" *Br.*, 1898. *Ecballium Elaterium* (L.) A. Rich., commonly known as the *wild* or *squirting cucumber*, is a perennial vine, indigenous to Mediterranean regions. It possesses a large fleshy root, from which rise several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green color. The flowers are yellow and axillary. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish color, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seeds with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and official title is supposed to have had a similar origin, though some authors maintain that the term *elaterium* was applied to the drug rather from the mode of its operation upon the bowels than from the projectile property of the fruit. It is derived from the Greek *ἐλαύνω*, *I drive,* or *ἐλατήρ*, *driver.* The word *elaterium* was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating. It is a native of the south of Europe, and is cultivated in Great Britain, where, however, it perishes in the winter. (For description of the culture in England, see *U. S. D.*, 19th edition, p. 432.)

Elaterium is the substance spontaneously deposited by the juice of the fruit, when separated and allowed to stand. Strong expression of the juice injures the product. When the fruit is sliced and placed upon a sieve, a perfectly limpid and colorless juice flows out, which soon becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white color, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of one-eighth of a grain. But the quantity contained in the fruit is very small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is often a weaker medicine, owing in part, perhaps, to adulteration, but much more to the fact that in order to increase the product, the juice of the fruit is often expressed with great force, and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposit the active matter.

The best elaterium is in thin flat or slightly curled cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray color becoming yellowish by exposure, of a feeble odor, and a bitter, somewhat acrid taste. It is pulverulent and inflammable, and so light that it floats when thrown upon water. When of inferior quality, it is sometimes dark-colored, much curled, and rather hard, breaking with difficulty, or presenting a resinous fracture. "In light, friable, flat or slightly curved, opaque cakes, about one-tenth of an inch (two and a half millimetres) thick; pale green, grayish-green, or yellowish-gray in color; fracture finely granular; odor faint, tea-like; taste bitter and acrid. It should not give the characteristic reactions with the tests for carbonates or for starch, and should yield half its weight to boiling *alcohol* (90 per cent.). When exhausted with *chloroform*, the solution evaporated, the residue washed with *ether*, and the process of solution, evaporation, and washing repeated, Elaterium should yield 25 per cent., or not less than 20 per cent., of Elaterin." *Br.*, 1898. For an assay of elaterium by Jones and Ransom, see *U. S. Dispensatory*, 19th ed., p. 432.

Maltese elaterium is in larger pieces, of a pale color, sometimes without the least tinge of green, destitute of odor, soft, and friable, and not infrequently gives evidence of having been mixed with chalk or starch. It sinks in water, and usually contains so little elaterin that it should be employed only as a source of that principle. In the analyses of T. A. Elwood, the average yield of English elaterium was 21.5 per cent., of Maltese elaterium 15.3 per cent. (*P. J.*, Nov., 1891.)

Clutterbuck first observed that elaterium resided in the portion of it soluble in alcohol and not in water. The subsequent experiments of Hennell, of London, and Morries, of Edinburgh, which were nearly simultaneous, demonstrated the existence of a crystallizable matter in elaterium which is the active principle, and has been named *elaterin.* (See *Elaterinum.*) According to Hennell, 100 parts of elaterium contain 42 of elaterin, 17 of a green resin (*chlorophyll*); 6 of starch, 27 of lignin, and 6 of saline matters.

Uses.—Elaterium is a powerful hydragogue cathartic, and in a large dose generally excites nausea and vomiting. Two-fifths of a grain (0.025 Gm.) of elaterium proved fatal by purging in an ill and feeble lady of 70 years. (*A. J. P.*, 1868, p. 373.) Because of its variability elaterium should never be employed, preference always being given to the official elaterin.

Elbon. *Cinnamoyl-para-oxyphenyl-urea.*—It occurs as white, tasteless crystals, very slightly soluble in water but readily dissolved by oils and alcohol. It is decomposed in the system and appears in the urine as a derivative of oxyphenyl-urea and hippuric acid. It is used as a stimulating expectorant, especially in *pulmonary tuberculosis* and *pneumonia.* According to Johannessohn (*B. K. W.*, 1913, p. 914), it also has an antipyretic action and increases the leucocytes. The *dose* is fifteen grains (1.0 Gm.).

Elemi. *Gum Elemi. Elemi,* Fr.—The name elemi is applied commercially to a large number of resins. The variety which is mostly used is known as *Manila* or *Philippine Elemi* and is derived from *Canarium commune* L. and probably also from *C. luzonicum* Miq. (Fam. *Burseraceæ.*)

According to Bacon (*Philippine Journal of Science,* 1909, iv, p. 93), the Manila elemi is derived from the *Canarium luzonicum* Miq. When first collected it is soft, but later becomes hard on exposure to the air and light, which has given rise to the belief that there were two varieties of the Manila gum. It is collected by incising the tree at the time when it is developing new leaves, the juice exuding through the bark and collecting in lumps at the point of the incision. This is the variety formerly recognized by the British Pharmacopœia.

There are a number of other commercial varieties of elemi. The so-called carana-elemi is obtained from *Protium Carana* (Humb.) L. March., a tree growing in Venezuela and Northern Brazil. Brazilian Almesseya-elemi is obtained from *Protium heptaphyllum* March., var. *Brasiliense* Engl. East African elemi is probably obtained from *Boswellia Frereana* Birdwood. Yucatan elemi is derived from *Amyris Plumieri* DC. All these plants belong to the *Burseraceæ.* The elemi is obtained by incisions into the trees, through which the juice flows and concretes upon the bark.

Carana-elemi occurs in masses of a greenish-yellow color, externally hard, internally soft, with a peculiar fennel-like aromatic odor. It is insoluble in water, soluble in sulphuric ether, chloroform, and benzene. According to Tschirch and Saal, carana-elemi contains 20 per cent. of exceedingly acrid resin. (*A. Pharm.*, Bd. 241, 1903.)

These are further distinguished as "hard" or "soft" elemi, which are differentiated by the fact that the "soft" elemi contains from 20 to 25 per cent. of volatile oil.

Elemi is in masses of various consistence, sometimes solid and heavy like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colors, generally greenish with intermingled points of white or yellow, sometimes greenish-white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odor, diminishing with age, and resembling to some extent that of lemon and fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. "Moistened with rectified spirit, it breaks up into small particles, which, when examined by the microscope, are seen partly to consist of acicular crystals." *Br.*, 1885. Elemi is sometimes adulterated with rosin and turpentine.

The two varieties of elemi that have been investigated chemically are the Manila, or soft elemi, and the Brazilian, or hard elemi. The Manila elemi contains 10 per cent. of an ethereal oil (made up of phellandrene and dipentene), *amyrin* (*manamyrin*) $C_{30}H_{50}O$, of which, according to Vesterberg, the isomeric varieties *a-* and *b-amyrin* are present, an amorphous *resin*, small amounts of *a-manelemic acid*, $C_{37}H_{56}O_4$, *β-manelemic acid*, $C_{44}H_{80}O_4$, *bryoidin*, $C_{20}H_{38}O_3$, and a bitter principle. The Brazilian elemi (*protium elemi*) contained *protomyrin*, 30 per cent.; *protolaminic acid*, 25 per cent.; and *protolaresine*, 37.5 per cent The protomyrin has the same melting point and formula as the amyrin from Manila elemi.

Elemi has properties analogous to those of the turpentines, but is exclusively applied to external use. In the United States it is rarely employed even in this way, except as a constituent of plasters prepared upon the large scale. In the pharmacy of Europe it enters into the composition of numerous plasters and ointments. *Unguentum Elemi* (*Br. Ph.*, 1885) was of the strength of about 20 per cent.

Elixir of Iron, Quinine, and Strychnine Phosphates. (*U. S. P. VIII.*) *Elixir Ferri, Quininæ et Strychninæ Phosphatum.*—The U. S. P. VIII process was: " Soluble Ferric Phosphate, *seventeen and one-half grammes;* Quinine, *eight and seventy-five hundredths grammes;* Strychnine, *two hundred and seventy-five milligrammes;* Phosphoric Acid, *two cc.;* Ammonium Carbonate, in translucent pieces, *nine grammes;* Alcohol, *sixty cc.;* Acetic Acid, *twenty-eight and sixty-five hundredths grammes;* Ammonia Water, Distilled Water, Aromatic Elixir, each, a *sufficient quantity,* to make *one thousand cc.* Dissolve the Quinine and Strychnine in the Alcohol, then add the Phosphoric Acid and *three hundred and fifty cc.* of Aromatic Elixir. Add the Acetic Acid to the Ammonium Carbonate, contained in a suitable vessel, and when solution is complete, neutralize with Ammonia Water and add enough Distilled Water to make the product measure *fifty cc.* Mix the solution of Ammonium Acetate with the solution of the alkaloids, and add enough Aromatic Elixir to make the liquid measure *eight hundred and eighty cc.* Dissolve the Ferric Phosphate in *thirty cc.* of Distilled Water, by the aid of a gentle heat, and if the solution be acid to litmus paper, neutralize exactly with Ammonia Water, and add enough Aromatic Elixir to make the product measure *one hundred and twenty cc.* Finally, mix the two solutions and filter, if necessary." *U. S. VIII.*

This elixir was introduced into the U. S. P. VIII because it is largely used and deserved recognition, but because of the darkening of the elixir and frequent precipitation it was omitted from the U. S. P. IX. The difficulty is largely caused by the attempt to produce phosphates of the several ingredients and as this form possesses no special medicinal value it was believed that the use of the more permanent elixir of iron, quinine, and strychnine of the N. F. V (see Part III) should be encouraged. The U. S. P. VIII process is essentially that recommended by Caspari, but as it did not prove satisfactory, Caspari has since recommended the following formula which is less likely to discolor or precipitate: Quinine (alkaloid), 8.75 Gm.; Strychnine (alkaloid), 0.275 Gm.; Ferric Phosphate (U. S. P.), 17.50 Gm.; Phosphoric Acid (U. S. P.), 2 cc.; Alcohol, 60 cc.; Acetic Acid (U. S. P.), 16 Gm.; Ammonium Carbonate, 5.1 Gm.; Distilled Water, Aromatic Elixir, of each, *a sufficient quantity,* to make 1000 cc. Add the ammonium carbonate, in firm translucent pieces, to the acetic acid contained in a beaker and when solution is complete, add 350 cc. of aromatic elixir and the phosphoric acid. Dissolve the quinine and strychnine alkaloids in 40 cc. of alcohol, add this solution to the acid mixture, and rinse the beaker or flask with 20 cc. of alcohol, adding this also to the previous mixture; now add sufficient aromatic elixir to bring the volume of the mixture up to 880 cc. Dissolve the ferric phosphate in 30 cc. of distilled water with the aid of heat, and when cool add sufficient aromatic elixir to bring the volume of the solution up to 120 cc. (If the iron solution shows an acid reaction with litmus paper, it should be neutralized nearly, but not entirely, by the cautious addition of ammonia water.) Finally, mix the two solutions and keep the finished product in dark, amber-colored bottles. The ferric phosphate and the alkaloids are retained in solution in the elixir with the aid of an excess of phosphoric acid, but this makes the elixir unpleasantly acid to the taste; ammonium acetate is used to retain the ferric phosphate in solution with the other ingredients and to make a finished elixir which can be mixed with aqueous solutions without producing turbidity, and remain clear at low temperatures. This elixir should be preserved in amber-colored bottles protected from the light, otherwise the pale greenish color which it has when first made will disappear and be replaced by a brownish tint followed often by precipitation. *Dose,* one to two fluidrachms (3.75–7.5 cc.).

This is one of three preparations which are frequently confused by physicians and pharmacists. The other two are official in the N. F. and are Elixir of Iron Quinine and Strychnine and Elixir of Iron Pyrophosphate, Quinine and Strychnine. Another disconcerting fact is that manufacturers have introduced preparations which are half the strength of the official preparations in Quinine and Strychnine. Pharmacists frequently purchase these substandard preparations and dispense them in ignorance of their character. Investigations of this condition by State Pharmacy Boards has frequently resulted in the penalizing of pharmacists who dispense any other than the official preparations.

Emery. *Lapis Smiridis, s. Smiris. Emeri, Corindon granuleux ferrifère,* Fr. *Smirgel, Schmirgel,* G.—A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. It is an impure variety of *corundum,* which is *alumina* (Al_2O_3), containing oxide of iron. It was formerly derived almost solely from the island of Naxos, in the Grecian Archipelago. Corundum is found abundantly in Northern Georgia, in North Carolina, and in Chester County, Pennsylvania. *Emery* is pulverized by grinding it in a steel mill, and the powder is kept in commerce of different degrees of fineness. It is used for polishing metals and hard stones. Compact corundum is now ground extensively for the manufacture of emery wheels, etc. Both corundum and emery have been largely replaced in use by the product of the electric furnace, *carborundum,* which is *silicon carbide* (SiC).

Emetine Bismuth Iodide. *Emetinæ Bismutho-Iodidum* (*N. N. R.* 1924) *Emetine Bismuthous Iodide.*—This is an odorless orange red powder sparingly soluble in water with partial decomposition. It is decomposed by strongly alkaline or acid solutions. It represents from 17 to 23 per cent. of emetine and from 15 to 20 per cent. of bismuth. Sollmann (*J. A. M. A.*, 1919, lxxiii, p. 1125) finds that it is freely soluble in a 1 per cent. solution of sodium bicarbonate.

The purpose of this combination is to present emetine in an insoluble form so that irritation of the stomach will be avoided. It is used for the treatment of *amebic dysentery* and it is claimed that the administration by mouth of the emetine bismuth iodide is equally efficacious, if not more so, than the hypodermic use of the soluble salts of the alkaloid. For summary of the literature see the report of the Council of Pharmacy and Chemistry (*J. A. M. A.*, 1918, lxxi, p. 2013).

Some authorities recommend that, in order to further guard against irritation of the stomach, it be given in salol coated pills, or in pills made with suet. The dose employed is about three grains (0.2 Gm.), corresponding to one grain of emetine, daily for three or four days.

Empyroform.—This is a condensation product of formic aldehyde and tar, forming a stable brown powder of a peculiar faint odor quite distinct from that of tar. Upon heating formic aldehyde is split off. It is insoluble in alcohol and water and soluble in acetone, caustic alkalies, and chloroform. It is used in inflammatory *skin diseases*, such as *acute* or *chronic eczema*, in the form of ointment in strengths of from 5 to 15 per cent. Both antipruritic and disinfectant properties are claimed for it. It has the advantage over tar of being less irritant.

Enomorphine.—This is claimed to be the sulphate of *allyl-morphine* $C_{17}H_{17}NO(OH)(OC_3H_5)$. It is asserted by Major and Wiki to possess the advantages of morphine and few of its disadvantages. (*Schweiz. Apoth. Ztg.*, 1915, 119.)

Eosin. *Bromeosin.* $C_{20}H_8Br_4O_5$.—A dye obtained by the action of phthalic anhydride upon phenols and introduction of bromine into the product. When phthalic anhydride acts upon resorcinol, $C_6H_4(OH)_2$, in the presence of a dehydrating agent like sulphuric acid or stannic chloride, at a temperature of 120° C., there is formed a compound resorcinphthalein, $C_{20}H_{12}O_5$, better known as *fluorescein* (see p. 1307). By the action of bromine upon this is formed *tetrabromfluorescein* or *eosin*, $C_{20}H_8Br_4O_5$. Soluble eosin is the potassium salt of this compound, $C_{20}H_6Br_4O_5K_2$. It forms a bronze-colored crystalline powder having a strong green reflection. Its solution in water is a red liquid having a fine green fluorescence. On the addition of hydrochloric acid the fluorescence is destroyed, the liquid becoming yellow. Eosin is largely used at present as a dye; to make a brilliant *red ink*, dissolve 5 grains of eosin and 10 grains of gum arabic in a fluidounce of water. According to Mandach (*K. S. A.*, 1907), eosin affords a most sensitive reagent for the occurrence of bile pigment in the urine. For this purpose a stock solution of 0.1 per cent. is diluted until the yellowish-red color becomes a pale pink showing a slight green fluorescence. In the presence of the bile this pinkish color is changed to a yellowish-brown, and later to a bottle-green. In normal urine no change of color is observed.

There is also sold under the name of *blue eosine* a *sodium iodeosine*, commercially known as *erythrosine*. It is a brown powder, soluble in water and used for dyeing wool, cotton and paper. It is also of use in histology as a stain for cell walls and contents.

Eosin Selenium is the name of a powder which has been used, experimentally, in investigations on the treatment of malignant tumors. The *dose* is one sixty-fourth of a grain (0.001 Gm.), to be increased if necessary.

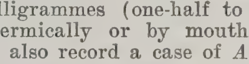
Ephedra. *Ephedra vulgaris* Rich. (Fam. *Gnetaceæ.*)—This gymnospermous plant is a straggling shrub with long-jointed and fluted green stems and scale-like opposite leaves forming at each joint a two-toothed sheath. It grows in Eastern Europe and Western Asia. It has been used as a medicine by the Chinese for thousands of years, being included in the collection made by the Emperor Shen-Nung about 1500 B.C.; in China it is known as *Ma huang*. For pharmacognostic description see Chen (*J. A. Ph. A.*, 1925, xiv, 189).

In 1887 Nagai isolated from this plant an alkaloid *ephedrine*, $C_{10}H_{15}ON$. Subsequently Merck found in the European variety an alkaloid which he called *pseudo-ephedrine*, apparently isomeric with that from the Asiatic variety. Ephedrine occurs as colorless crystals melting at 214° C., while pseudo-ephedrine forms yellowish crystals and melts at 175° C. Spehr (*A. J. P.*, 1892, 234) found in the *E. Monostachya* L. an alkaloid, $C_{13}H_{19}ON$, which was physiologically inert.

Ephedrine has been studied by Miura, Amatsu and Kubota and by Chen and Schmidt (*J. P. Ex. T.*, 1924, xxiv, p. 339) with concordant results. Chemically it is closely related to epinephrin, differing only in that two hydroxyl groups of the latter have been replaced by hydrogen atoms. In physiological action also it resembles epinephrin. It causes a marked rise in the blood pressure with an increase of both the rapidity and excursion of the heartbeat. The rise of blood pressure is also due in part to vasomotor stimulation. It causes dilatation of the pupil, whether injected into the blood stream or applied locally, without loss of the power of accommodation. It relaxes the intestinal muscle and apparently also the bronchial. All these effects seem to be due to stimulation of the sympathetic nervous system. Chen and Schmidt find that it differs from epinephrin chiefly in the persistence of effect and in the fact that it is active when taken by the mouth. A dose of 60 milligrammes in a human being produced a rise of blood pressure of 20 millimeters that lasted for two hours. They have used it clinically as a circulatory stimulant in *doses* of from 40 to 60 milligrammes (one-half to one grain), either hypodermically or by mouth with good effects. They also record a case of *Addison's disease* in which the drug produced a marked alleviation of symptoms. An alkaloid has also been discovered in *Ephedra distachya* L., a shrub whose branches and root are used in Siberia as a remedy in *gout* and *syphilis*. According to Kobert, this alkaloid is essentially different from *ephedrine*, in not being mydriatic or poisonous. *E. monostachya* contains a crystalline base melting at 112° C. and having the formula $C_{13}H_{19}ON$. This latter, as stated by Kobert, is not mydriatic or poisonous. See paper by E. Schmidt, *A. Pharm.*, 1912, ccl, 154, 161.

Ephedra nevadensis S. Wats. and *E. antisyphilitica* C. A. Meyer, which grow abundantly in the extreme Western United States, are used under the names of *caynote*, *canutilo*, *whorehouse tea* as a remedy in *gonorrhea*. Loew thinks that their virtues reside in a peculiar tannin. *Dose*, of fluidextract, from one to two fluidrachms (3.75–7.5 cc.). In Texas *E. trifurca* Torr. is similarly employed.

Epicarin.—A condensation product of creosotinic acid and naphthol which, according to Eichengrün, is *β-oxynaphthyl-o-oxy-metatoluylic acid* thus:



$$C_6H_3\begin{array}{l}/COOH\\—OH\\\backslash CH_2—C_{10}H_6OH\end{array}.$$

Epicarin forms slightly yellowish crystals or powder with a faint odor, melting at 190°–195° C., difficultly soluble in water but freely soluble in alcohol and ether as well as in soaps. It is said to be slightly poisonous, and was primarily introduced into veterinary medicine, especially for the treatment of *mange*, but has been used by Kaposi, Monti, and other dermatologists in *scabies, ringworm, prurigo*, and allied skin diseases as a substitute for naphthol. Its application is sometimes followed by irritation, which, though usually slight, may lead to papular and eczematous eruptions. It is claimed that the remedy is less poisonous than naphthol. In Kaposi's clinic no toxic symptoms followed covering the entire body of children with 10 per cent. ointment. Five to twenty per cent. ointment is used *pro re nata*.

Epichlorhydrin. *Chloropropylene oxide.* C_3H_5ClO.—A colorless liquid of specific gravity of 1.203 at 0° C. and miscible with alcohol and ether. It is used as a general solvent for resins, having a solvent action even on celluloid. It is incompatible with alkaline hydroxides or carbonates, and it should be protected from exposure to air, which turns it red.

Epidermin.—A surgical dressing made by fusing 15 Gm. of white wax, and triturating in a warm mortar with 15 Gm. of powdered acacia until uniform, and adding a boiling mixture of 15 Gm. each of water and glycerin, and stirring until cold. Valentine and Schwartz have given the name *epidermin* to an ointment vehicle said to be composed of fluorxylol and difluordiphenyl.

Epifagus. *Epiphegus. Epifagus virginiana* (L.) Bart. (*Leptamnium virginianum* (L.) Raff.) (Fam. *Orobanchaceæ.*) *Beech-drops. Cancer Root. Orobanche de Virginie*, Fr. *Krebswurz*, G.—This is a parasitic, fleshy plant, found in Northeastern America, growing upon the roots of the beech tree. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate *ulcers* of a cancerous character, to which it was directly applied. Other species of *Orobanchaceæ*, growing in America and Europe, have also been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom rape.* C. Charaux believes that *chlorogenic acid*, which can be easily converted into *caffeic acid*, exists in plants of the Fam. *Orobanchaceæ* and other families. The allied plants, *Conopholis americana* (L. f.) Wallr. (*Orobanche americana* L. f.) and *Orobanche uniflora* L., growing throughout the United States, are used for the same purposes as the species above noticed, and, like it, are unfortunately called *cancer root.*

Epigaea. *Epigaea repens* L. *Trailing Arbutus. Ground Laurel. Mayflower. Gravel Plant.*—This is a small prostrate or trailing ericaceous plant, having woody stems; evergreen, entire, cordate-ovate leaves, and small very fragrant rose-colored dimorphic, subdioecious flowers, which appear early in the spring. It is found in the sandy woods or rocky soil, and grows on the sides of hills with a northern exposure. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (*Flora Cestrica*, 259.) Jefferson Oxley has found in this plant arbutin, urson, ericolin, (the same constituents as are in uva ursi), tannic and formic acids, and a principle allied to gallic acid. (*A. J. P.*, xliv, 253.) Eli Ives of New Haven, Connecticut, in 1849, highly commended epigaea as a substitute for uva ursi, and we now know that the two drugs contain the same active principles. The decoction of the leaves and stem may be used freely.

Epilobium. *Epilobium angustifolium* L. (*Chamænerion angustifolium* Scop.) *Willow-herb. Fire-weed. Herbe de St. Antoine*, Fr. *Weidenröschen, Antonskraut*, G. (Fam. *Onagraceæ.*)—There are several indigenous species of *Epilobium*, which have the common name of willow-herb, from the resemblance of their leaves to the willow, all of which probably have nearly identical properties. The *E. angustifolium* is the largest of them. Its leaves and roots are said to be demulcent, tonic, and astringent. They are used by the eclectics, generally and locally, in decoction, infusion, or cataplasm, as astringents. Oliver reports (*B. M. J.*, 1897, ii) violent poisoning with epileptiform convulsions caused by *E. hirsutum* L. Under the name of *Kaporie tea*, the leaves of *E. angustifolium* and of *E. hirsutum* are largely used in Russia as a beverage.

Equisetum. *Equisetum hyemale* L. *Horsetail. Scouring Rush. Prêle.* Fr. *Schachtelhalm.* G. (Fam. *Equisetaceæ.*)—A horsetail indigenous to Europe but naturalized in the United States, growing abundantly in wet places. It is characterized by having erect stems which are mostly simple and ridged, attaining a height of 9 dm. and further by showing green parenchyma continuous over the vallecular holes separated by bast fibers beneath the ridges when the stems are examined in cross-sections. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the silicious character of the stems. Examined by F. J. Young (*A. J. P.*, 1886, 419), it yielded to petroleum benzin as a solvent 1.4 per cent. of a brownish-green, semi-liquid, fixed oil, which was readily saponified. It also contained a green semi-solid resin, sugar, and mucilage. The infusion of the whole plant is used sometimes in *dropsical* and *renal diseases*, but Cow (*A. E. P. P.*, 1912, lxx, p. 393) has shown that the diuretic action is very feeble.

Erechtites. *Erechtites hieracifolia* (L.) Raf. *Fire weed.*—An annual composite, growing in moist woods and recent clearings in lower Canada and the United States. It possesses alternate, lanceolate to oblong, cut-toothed leaves and heads of whitish flowers arranged in panicles or corymbs. Its odor is rank and its taste bitter, and slightly acrid. It yields its virtues to water. It has been recommended in *dysentery.* It is prone to infest the peppermint fields of Michigan, and its oil is said sometimes to deteriorate the oil of peppermint from that region. It has been shown, however, that *Erigeron* (*Leptilon*) *canadensis* L. is far more injurious (see Erigeron).

Erepton.—This preparation, whose use is based upon the discoveries of Abderhalden that the system is capable of synthesizing albumin from the amino-acid, is prepared by digesting lean meat with pancreatic and intestinal secretions. It is a brown hygroscopic powder, readily soluble in water, containing 12 per cent. of nitrogen, and does not give the Biuret reaction. It has been recommended by Jacobson and Rawald (*Ther. Geg.*, 1911, p. 119) for rectal feeding. They administered 250 cc. (8 fluidounces) of a 5 per cent. solution three to six times a day by enemata. They found that 85 per cent. of the nitrogen was absorbed.

Erigeron. *Fleabane. Scabious. Sweet Scabious. Daisy Fleabane. Herbe d'érigeron, Herbe de Vergerette*, Fr. *Berufkraut*, G.—The U. S.

V recognized three species of *Erigeron* (Fam. *Compositæ*), namely, *E. heterophyllum* Muhl., *E. philadelphicum* L. and *E. canadense* L. Under the name of erigeron and under the title of *Erigeron Canadense* it recognized the *E. Canadensis* [*Leptilon canadense* (L.) Britt.]. *Horseweed. Mare's tail. Fire-weed. Butter-weed. Colt's-tail.*

All of these species are abundant weeds in the northern and middle sections of the United States and Canada; fleabane has been reported as very troublesome on the peppermint plantations of the West. All portions of the plants are somewhat aromatic. Whatever virtue they possess is due to their volatile oil, of which they yield 0.2 to 0.4 per cent.

The oil of erigeron remained official in the U. S. VIII but was dropped at the ninth revision.

The U. S. VIII recognized, under the name of *Oleum Erigerontis*, the *oil of Canada fleabane.*

Oil of erigeron is of a light straw color, a peculiar, aromatic, persistent odor, and a characteristic taste. By exposure it becomes darker and thicker and eventually resinifies. Its reaction is neutral. Its sp. gr. is about 0.850, increasing with age (0.855 to 0.890, *Schim. Rep.*). It consists chiefly of dextrogyrate limonene, together with some terpineol. (*A. J. P.*, 1893, 420.) It was officially described as "a pale yellow, limpid liquid rapidly becoming darker and thicker by age and exposure to the air, having a peculiar, aromatic, persistent odor, and an aromatic, slightly pungent taste. Specific gravity, 0.845 to 0.865 at 25° C. (77° F.). Soluble in an equal volume of alcohol (distinction from *oil of fireweed* derived from *Erechtites hieracifolia* Rafinesque (Fam. *Compositæ*) and from *oil of turpentine*). It is dextrogyrate, the angle of rotation being not below +45° in 100 mm. tube, at a temperature of 25° C. (77° F.)." *U. S. VIII.* When distilled without water, it comes over colorless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It is slowly reddened by potassium hydroxide, combines with iodine without explosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, *A. J. P.*, xxvi, 502.) For an account of the difference in properties between this oil and that from *Erechtites hieracifolia*, see Todd, *A. J. P.*, 1887, p. 302; Rabak, *Ph. Rev.*, 1905, 81, and also *Ph. Rev.*, 1906, 326.

It was first brought into notice by the so-called eclectic physicians, who use it in *diarrhea, dysentery*, and the *hemorrhages*, and apparently it is a valuable remedy in *hemoptysis* when there is no fever or other marked evidence of constitutional irritation. It probably acts like the oil of turpentine as a hemostatic, but is much less irritant and stimulating.

Dose, ten minims to half a fluidrachm (0.6–1.8 cc.), repeated every hour or two.

For further information concerning these drugs see *U. S. D.*, 19th ed., p. 1479.

Eriobotrya. *Eriobotrya japonica* Lindl. *Loquat. Japanese Medlar. Bibacier. Néflier du Japon. Nestole di Giappone.* (Fam. *Rosaceæ.*)—A small tree, indigenous to Japan and extensively cultivated. The fruit closely resembles the apricot and has a sweetish acid pulp. The seeds of this tree are said to contain amygdalin and emulsin, and to yield hydrocyanic acid in poisonous quantities. (Hérissey, *A. Pharm.*, ccxlv, 1907.)

Erodium. *Erodium cicutarium* L. *Stork's-bill.*—An annual hairy plant belonging to the *Geraniaceæ.* It grows in Europe, Asia, Northern Africa and is widely cultivated, being found naturalized about cities in the United States. Many years ago it was recommended by W. Abbots Smith (*Am. J. M. S.*, 1865) in *dropsy.* It has been revived by Von Dongen (*C. D.*, 1916, lxxxviii, p. 41) as a substitute for hydrastis in *uterine hemorrhages.*

Eryngium. *Eryngium aquaticum* L. *Button Snakeroot. Corn Snakeroot. Rattlesnake's Master.*—The *button snakeroot* or *water eryngo* is an indigenous umbelliferous plant which grows in low wet places near the coast from New Jersey as far south as Florida and Texas. The root, which is the medicinal portion, has a bitter, pungent aromatic taste, provoking, when chewed, a flow of saliva. It is said to be diaphoretic, expectorant, in large *doses* emetic, and the plant has been used as a substitute for senega.

Erythrina.—The bark of the Australian species *Erythrina Broteroi* (Fam. *Leguminosæ*) is said to contain an alkaloid, *erythrinine*, while the Mexican species, *Erythrina caralloides* DC., bears poisonous seeds in which Altamirano has found *erythroidine*, a powerful paralyzant of the motor system, *erythroresin*, an emetic, *coralin* and *erythric acid.* The *extract* has been suggested as a substitute for curare. (*B. S. Ph. Br.*, 1900.) Langham obtained from the seeds of *E. zeyheri* (which have a scarlet testa), *erythrine*, 15 per cent. (*C. D.*, 1911, 134.)

Erythrina lithosperma Blume. (*Hypaphorus subumbrans* Hassk.)—From the seeds of this beautiful leguminous tree, largely grown for shade in the coffee gardens of Java, P. C. Plugge has obtained *hypaphorine* $C_{14}H_{18}O_2N_2$, a tetanizing alkaloid. (*A. E. P. P.*, xxxii.) (See also Romburgh and Barger, *Tr. Chem. Soc.*, 1911, xcix, 2068.)

Erythrol Tetranitrate. *N. N. R.* 1924. (*Tetranitrol. Butane tetrol.*) $C_4H_6(NO_3)_4$.—*Erythyrol tetranitrate* is solid and crystalline, and melts at 61° C. When pure it is colorless, and if kept in a dark and moderately cool place is fairly stable. If exposed to warmth, and especially sunlight, it rapidly undergoes decomposition, turning yellow and giving off nitrous fumes. It is also capable of rapid decomposition, and death has been caused by the explosion following its trituration in a mortar with glucose. (*B. M. J.*, 1896, i.) Its solubility in water is slight, but it dissolves readily in alcohol and in ether. It is a vasodilator, and belongs to the group of which glyceryl trinitrate (glonoin) or nitroglycerin is the representative. Blood pressure experiments show that the nitrates of erythrol and mannitol have a less marked and more prolonged action than those of glycerol and glycol. In man the effects of the remedy are said not to be apparent in less than half an hour and to last for two or three hours. It may be used in all cases for which glyceryl trinitrate is employed, and has been especially commended in *angina pectoris.* Its alcoholic solution is explosive, so that it should always be used in tablets, in preparing which great care is necessary. *Dose*, from a half to one grain (0.032–0.065 Gm.).

Erythronium. *Erythronium americanum* Ker. *Yellow Adder's Tongue. Dog's Tooth Violet.*

Scrofula Root. Yellow Snowdrop. Rattlesnake Violet.—This is an indigenous, perennial, lilaceous plant found in early spring in valleys of rich woods from New Brunswick to Florida and west to Ontario and Arkansas. Its light yellow, often spotted, and nodding flowers appear the latter part of April or early in May. All parts of it are active. In the *dose* of twenty or thirty grains (1.3 or 2.0 Gm.) the recent bulb is emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying.

Eschscholtzia. *Eschscholtzia californica. Chamisso. California Poppy.*—Attention has been brought to this California member of the *Papaveraceæ,* as a powerful soporific and analgesic, which is free from the disadvantages of opium. The plant is extensively cultivated and there are now a number of garden varieties. Bardet and Adrain (*G. H. M. C.*, Nov., 1888) assert that they have obtained a glucoside, an alkaloid, and morphine in the proportion of from five to six grains in two pounds of the dried product. According to Fischer and Tweeden, there are seven alkaloids in *Eschscholtzia californica; protopine, β-* and *γ-homochelidonine,* "alkaloid *a*," "alkaloid *b*," *sanguinarine* and *chelerythrine.* As far as could be determined from the small quantities obtained, the alkaloids designated as *a* and *b* differ from any other alkaloids thus far known. (*A. Pharm.*, 1902, No. 7.) Most of these alkaloids are found also in *Sanguinaria* and *Chelidonium* (which see for further information). The narcotic power of the drug seems to be very weak, since, according to Bardet, three drachms were necessary to kill a rabbit. Ter-Zakariant (*G. M. P.*, Feb., 1899) states that the alcoholic extract acts as a respiratory depressant and narcotic, affecting in toxic dose also the spinal cord. Dujardin-Beaumetz has used the extract in commencing *doses* of twelve grains (0.78 Gm.), increasing to one hundred and eighty-five grains (12 Gm.) a day, and affirms that it is a harmless soporific and analgesic.

Escorcin. *Escorcinal, Aescorin.* $C_9H_8O_4$.—This is prepared from *aesculetin* (a decomposition product of aesculin) by the action of sodium amalgam. It is a brown powder, soluble in alkalies, imparting to the solution a green color which quickly changes to red. It is used in discovering defects in the cornea and lesions in the conjunctival epithelium, the red color which it imparts to the lesions being much more distinct on the iris than the green color of fluorescin. *Dose,* one drop of a 10 to 20 per cent. aqueous solution.

Ethyl Bromide. *N. N. R.* 1924. *Æthylis Bromidum. Bromide of Ethyl. Hydrobromic Ether. Æther Bromatus,* G. P. *Bromure d'éthyle,* Fr. *Bromäthyl,* G. C_2H_5Br.—The hydrobromic acid ester of ethyl alcohol containing approximately one per cent. of ethyl alcohol. This ether was discovered by Sérullas in 1827, who prepared it by acting on alcohol with bromide in the presence of phosphorus. (*Ann. Ch. Phys.*, xxxiv, 99.) Personne suggested the use of amorphous phosphorus, as less dangerous than ordinary phosphorus, and more convenient to manipulate (*C. R. A. S.*, iii, 468.) A process was also recommended by Remington, based upon Personne's suggestion. (*Proc. A. Ph. A.*, 1877.) De Vrij proposed to decompose potassium bromide with sulphuric acid in the presence of alcohol, and a modification of his method is now generally employed. (For description of methods of manufacture, see *U. S. D.*, 19th ed., p. 1480; *A. J. P.*, 1879 and 1880; *Ph. Centralh.*, 1887, xxviii.)

Ethyl bromide is a colorless, strongly refractive, very volatile liquid, not inflammable, having an agreeable odor, and a hot, saccharine taste. Its sp. gr. is 1.453 to 1.457. It boils at from 38°–40° C. It is very sparingly soluble in water, freely soluble in alcohol and ether. When a small portion is evaporated from a porcelain plate by causing it to flow to and fro over the surface, little or no foreign odor is yielded as the last portions pass off, and the plate is covered with a slight deposit of moisture.

Shaken with distilled water, ethyl bromide should not show any acid reaction from hydrobromic acid, nor should it cause any appreciable turbidity with silver nitrate. Shaken with an equal volume of pure concentrated sulphuric acid, no color should develop even after an hour's time; otherwise ethylene bromide may be present. Dropped slowly into potassium iodide solution the drops of the ethyl bromide should settle to the bottom of the vessel without developing any appearance of violet color, which would indicate free bromine. Ethyl bromide should be kept in small, opaque bottles containing not more than 50 cc., completely filled and well stoppered. It must not be confused with ethylene bromide which is a very poisonous compound having a specific gravity of over 2.1. (Fischer, *Die Neueren Arzneimittel,* 6te Aufl., 74.)

Ethyl bromide was introduced some years ago as an anesthetic especially suitable for short operations. Its advantages were the rapidity of its action and the relative absence of nausea. H. C. Wood (*P. M. T.*, 1879 and 1880, x) found that it acted upon the system much like chloroform, but Hamœker (*International Clinics,* Dec. 20, 1891) affirms that in the lower animals death always occurred through arrest of the respiration. It has, however, been found to be a dangerous anesthetic; Gurlt (*A. K. C.*, lv) estimates the mortality at 1 in 5400. A serious practical objection to its use is the ease with which it undergoes decomposition on exposure to light. Its range of usefulness is similar to that of ethyl chloride, but it does not appear to possess any sufficient advantage over the latter to justify its employment. Ethyl bromide has been especially recommended for use in *parturition,* it being stated that it suspends the pain of the uterine contractions without influencing their force.

Ethyl Carbamate.—*Aethylis Carbamas,* U. S. IX. *Ethyl urethane, Urethane; Carbamin-säure-ethylester, Aethyl-urethan,* G.; *Eter Carbamico,* Sp.

"The ethyl ester [$C_3H_7O_2N$ or $CO(OC_2H_5)-NH_2 = 89.07$] of carbamic acid" (*U. S. IX*) is no longer official. It is made by allowing ammonia to act upon ethyl carbonate, when urethane and ethyl alcohol are produced, or by heating urea nitrate with alcohol to from 120° to 130° C., resulting in the formation of ethyl carbamate and ammonium nitrate. It is also made by the action of ammonia upon ethyl chloroformate  $CO\begin{cases}Cl\\OC_2H_5\end{cases}$ which is prepared by the action of phosgene on antipyrine in benzene solution.

Another process is by the interaction of potassium isocyanate and alcohol in the presence of hydrochloric acid. Still another process is by the action of carbamic chloride (produced by the action of phosgene on ammonium chloride) on dehydrated alcohol.

It was officially described as in "colorless, columnar crystals or scales, odorless, and having a cooling, saline taste. One Gm. of Ethyl Carbamate dissolves in 0.45 mil of water, 0.8 mil of alcohol, 2.5 mils of glycerin, 0.9 mil of chloroform, 1.5 mils of ether, and in 32 mils of olive oil, at 25° C. Its aqueous solution (1 in 20) is neutral to litmus. Ethyl Carbamate melts between 48° and 50° C. Add 1 Gm. of Ethyl Carbamate to 5 mils of sulphuric acid and heat it gently; decomposition follows with the evolution of carbon dioxide (alcohol and acid ammonium sulphate remain in solution). Heat 1 Gm. of Ethyl Carbamate with 5 mils of concentrated potassium hydroxide solution; ammonia gas is given off, recognizable by its odor. Dissolve about 0.5 Gm. of Ethyl Carbamate in 5 mils of distilled water with about 1 Gm. of dry sodium carbonate and about 0.01 Gm. of iodine, and warm the solution; yellow crystals of iodoform separate on cooling. Incinerate about 2 Gm. of Ethyl Carbamate; not more than 0.05 per cent. of ash remains. Dissolve about 2 Gm. of Ethyl Carbamate in 2 mils of distilled water and add 5 mils of nitric acid to the solution; no white precipitate is produced (*urea*). Not more than slight opalescence results from the addition of a few drops of silver nitrate T.S. to 10 mils of an aqueous solution of Ethyl Carbamate (1 in 20) (*chloride*). Mix 2 mils of the aqueous solution (1 in 20) with 1 mil of ferrous sulphate T.S. and pour the mixture upon 2 mils of sulphuric acid, so as to form a separate layer; no red or brown zone appears (*nitrate*). When it is heated with ammonia to 180° C. urea is formed." *U. S. IX.*

Uses.—Ethyl carbamate is one of the safest of the somnifacient drugs. In therapeutic doses it has no perceptible effect upon the respiration or circulation, its physiological action being limited almost solely to a depressant influence upon the cerebrum, although large doses also have a depressant influence upon the motor areas in the spinal cord. In ordinary quantities it does not lessen the susceptibility to pain, but toxic doses will produce a condition of anesthesia. In the lower animals, after fatal doses, the respiration becomes slower, there is complete unconsciousness, loss of reflexes, fall of body temperature, and some depression of the circulation, death being due to asphyxia. Although in the milder forms of *insomnia* its freedom from toxicity makes it a very useful remedy, in severe cases its action is uncertain. According to Rappaport (*Z. E. P. T.*, 1911, ix, p. 39) it greatly enhances the narcotic effects of opiates and bromides. It has also been used by Jackman and others (*L. L.*, June, 1886) in various forms of *convulsions*. *Dose*, fifteen to forty-five grains (1–3 Gm.).

Ethyldiiodo-salicylate. *Diiodosalicylic ether.* $C_6H_2I_2(OH).COOC_2H_5$.—White crystals, soluble in alcohol, fixed oils, and slowly soluble in water. Melting point, 132° C. It is used as a succedaneum for iodoform in surgery.

Ethyl Iodide. *Hydriodic Ether. Ethyl-hydriodic Ester. Iodure d'éthyle, Ether hydriodique,* Fr. *Jodäthyl, Jodwasserstoffäther,* G. C_2H_5I.—This liquid may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The residue of the distillation, as ascertained by D. K. Tuttle, is *ethylphosphoric acid.* Personne (*C. R. A. S.*, li, 468) proposed to use amorphous phosphorus instead of the ordinary kind, thus avoiding danger. For description of his process see *U. S. D.*, 19th ed., p. 1481.

Ethyl iodide is a colorless non-inflammable liquid, insoluble in water, with a penetrating ethereal odor and pungent taste. Its density is 1.92, and boiling point from 71°–72° C. Exposed to the air it becomes red from the liberation of iodine; the change in color is said to be prevented by adding to the bottle containing it a globule of mercury but the propriety of such a practice should be questioned unless it can be shown that no mercuric iodide enters solution.

Huette has proposed this ether, placed under a layer of water, as a medicine, to be used by inhalation. Fifteen or twenty inspirations suffice to impregnate the system with iodine. It acts as a powerful anesthetic, when inhaled for a sufficient time. It is said to increase the appetite, render the pulse fuller, and give vivacity to the feelings and activity to the intellect. (See *A. J. P.*, xxiii, 156.) James Turnbull, of Liverpool, and Henry Fischer, of New York, have used this ether by inhalation with satisfactory results in *chronic bronchitis* and *phthisis.* The *dose* is fifteen drops (0.75 cc.) three or four times a day, inhaled from a handkerchief. Ethyl iodide often has an unpleasant odor from the presence of foreign substances which renders it offensive to patients. Phosphorus is a common and injurious impurity.

According to Linosier and Lannois (*S. M.*, 1897), ethyl iodide affords an excellent method of affecting the general system by external application. Absorption of the iodine is rapid; the liquid should be applied with a brush and then covered with paraffined paper; after applying two fluidrachms they recovered thirteen grains of iodine from the urine.

Ethyl Salicylate. $C_6H_4OHCO.O.(C_2H_5)$. *N. N. R.* 1924. *Sal Ethyl.*—This is the salicylic acid ester of ethyl alcohol and is analogous to methyl salicylate. It is a transparent, colorless, volatile liquid, possessing a pleasant characteristic odor and taste. Sp. gr. 1.132 at 20° C. and boiling point 231.5° C.

Ethyl salicylate was suggested by Houghton (*A. J. Phys.*, 1905, p. 331) as a substitute for methyl salicylate in the treatment of *rheumatism.* He asserts that it is only one-half as toxic as the methyl ester and that it is absorbed rapidly from the intestinal tract, although not through the skin. The *dose* is five to twenty minims (0.3 to 1.2 cc.) several times daily.

Ethyl Valerate. $C_7H_{14}O_2$.—This compound is prepared by distilling sodium valerate with alcohol and an acid (HCl or H_2SO_4). It is a liquid having a strong odor with the characteristic valeric taste. It is used in *asthmatic* complaints as an antispasmodic and sedative. *Dose,* one to two drops during attacks.

Ethylene. *N. N. R.* 1925. (C_2H_4).—This is a colorless gas with a characteristic sweetish odor and taste, with a specific gravity of 0.978 as compared with the air. It may be prepared by heating alcohol with sulphuric acid or by passing CO over finely divided platinum at 100° C. It is highly inflammable and may explode from contact with a flame or an electric spark. Brown (*J. A. M. A.*, 1924, lxxxii, p. 1039) has found that mixtures of air and ethylene containing 5 to 10 per cent. of the latter are explosive but that 25 per cent. of ethylene with 75 per cent. of air is not, and that less than 3 per cent. of ethylene in the air is also not explosive, and concludes that it would take six hours of continuous anesthesia to make a sufficient concentration of the gas in a room of 2700 cubic feet to form an explosive mixture. Davis (*J. A. M. A.*, 1924, lxxxii, p. 1607), however, has reported an instance in which the flame of ignited ethylene vapor passed for a considerable distance through the air, eventually exploding the anesthetic mask with painful injuries to the patient.

The introduction of ethylene gas as a surgical anesthetic was the result of experiments by Brown and by Luckhardt and Carter (*J. A. M. A.*, 1923, lxxx, p. 765) on lower animals. Concentrations of 90 per cent. of ethylene with 10 per cent. of oxygen produces anesthesia and abolition of motor reflexes. Trials on human beings indicate that it is more powerful than nitrous oxide gas and that the stage of surgical anesthesia is preceded by one of analgesia. It apparently does not cause irritation of the respiratory tract. It has the advantage over nitrous oxide of producing better muscular relaxation without cyanosis; its disadvantages are the odor, which to some is offensive, and the inflammability. It has not been used enough for its relative danger to be determined.

Ethylene gas is supplied condensed in metallic cylinders and the technic of its administration is similar to that of nitrous oxide.

Ethylene Bromide. *Brom-ethylene. Æthylenum Bromatum.* $C_2H_4Br_2$.—This is a colorless oily liquid smelling like chloroform, with a sweet burning taste. It boils at 131.6° C., and solidifies at 0° C. to a crystalline mass; sp. gr. at 20° C. 2.178. It is insoluble in water, miscible with alcohol in all proportions. In experiments made by Scherbatscheff (*A. E. P. P.*, 1902, xlvii) *ethylene bromide* was found not to act as a true anesthetic in the lower animals, but to produce serious symptoms, usually ending in death. The chief medicinal importance of this agent grows out of its liability to be confounded with the ethyl bromide, death in this way having been produced. Ten fluidrachms of it were inhaled without the production of anesthesia, followed by uncontrollable vomiting and complete suppression of urine. On account of its containing over 85 per cent. of bromine, Donath has used it in *epilepsy.* He gives it in an emulsion with oil, or mixed with almond oil in capsules. Children from eight to ten years begin with ten drops (0.5 cc.) of a 5 per cent. solution; the adult *dose* is two to four minims (0.12–0.25 cc.) of ethylene bromide, three times a day. (See also *P. J.*, xxi, 1068.)

Ethylene Diamine. (*Ethane diamine.*) $CH_2(NH_2).CH_2(NH_2)$.—It is a colorless, thick liquid having the sp. gr. 0.87, boiling at 117° C., having a strong alkaline reaction, an ammoniacal odor and a caustic taste. It is said to be a noncorrosive solvent for false diphtheritic membranes. used in a diluted form. A solution in water of 25 per cent. of *ethylene diamine* and 25 per cent. of trikresol is sold under the proprietary name of *kresamine,* to be used in dilutions of from 2 to 25 per cent. A silver preparation of ethylenediamine used under the name of *Argentamin,* which see under the name of *Euphyllin,* a derivative of ethylene diamine, has been used by Addicks (*D. A. K. M.*, July 25, 1922) to increase the coagulability of the blood in *internal hemorrhages.*

Ethylene Dichloride. *Bichloride of Ethylene. Dutch Liquid. Æthyleni Bichloridum. Æthylenum Chloratum. Elaylum Chloratum. Liquor Hollandicus. Æthylenchlorid, Elaylchlorid,* G. $C_2H_4Cl_2$.—By the mutual action of chlorine and olefiant gas an oily liquid is obtained, discovered by four associated Dutch chemists, and called *Dutch liquid.* Aran found that the monochlorinated Dutch liquid (*monochlorethylene chloride,* $CH_2Cl,CHCl_2$) had a useful anesthetic power, but its cost proved to be too high to allow of its general use at that time as a therapeutic agent. In consequence of this objection to the monochlorinated liquid, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of successive portions of chlorine on hydrochloric ether, C_2H_5Cl; under these circumstances the hydrogen is replaced by the chlorine, atom for atom, and there are formed the five following compounds: $C_2H_4Cl_2$; $C_2H_3Cl_3$; $C_2H_2Cl_4$; C_2HCl_5; C_2Cl_6. Of this series, the first four members are isomeric with the corresponding Dutch liquid; and the fifth is a chloride of carbon, frequently called *carbon sesquichloride.* The first member, though identical with the Dutch liquid in elementary composition and having a vapor of the same density, has, nevertheless, a lower boiling point, *i.e.*, 60° to 64° C., while the Dutch liquid boils at 84.9° C.; it is also different in chemical properties. The Dutch liquids were chlorides of ethylene while those of Mialhe and Flourens belonged to the ethylidene series.

Mialhe and Flourens proposed the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anesthetic, under the indefinite name of *chlorinated muriatic ether.* Taube (*A. J. P.*, 1880, 603, and 1881, 119) proved the availability as anesthetics of monochlorethylidene chloride, CH_3,CCl_3, and of monochlorethylene chloride, $CH_2Cl,CHCl_2$.

The precise action of the various esters upon the organism is unknown. The committee of the British Association found (*B. M. J.*, i, 1879) the *ethene dichloride* ("formerly named *ethylene dichloride,* or Dutch liquid, $C_2H_4Cl_2$") to cause convulsions in the lower animals, while E. T. Reichert (*P. M. T.*, xi, 518) found that "ethylene dichloride" produces anesthesia with the usual stages, and that, like chloroform, it depresses the heart and steadily lowers the arterial pressure. His experiments seem to show, however, that its action upon the heart is much less powerful than that of chloroform, and in all of its trials the animal died of centric respiratory paralysis while the heart was still maintaining some degree of circulation. He believes, therefore, that it is a much safer agent than chloroform, ranking it between the latter and ether. It is evident that Reichert was not using the same agent as the English committee were, but exactly what he did have is uncertain. Dr. A. W. Wallace found ethylene dichloride useful in dermatological practice. (*P. J.*, 1910, 787.)

Ethylidene Chloride, *Chlorinated hydrochloric ether, Alphadichlorethane Ethidene bichloride* $CH_3,CHCl_2$), is a colorless, very mobile, neutral liquid, having an aromatic ethereal odor, and a hot, saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, is of sp. gr. 1.174 at 17° C., and boiling at 60° C. It can be distinguished from chloroform in that it combines with chlorine even in the dark, liberating hydrochloric acid. The British Association Committee (*B. M. J.*, 1879, i) believed it to be a valuable anesthetic, and it was tried on human beings by Snow and by Binz with satisfaction (*M. T. G.*, 1879, i); but Reeve finds (*N. R.*, 1880, 334) that in animals it lowers the arterial pressure, and it has failed to obtain general recognition.

Eucaine Lactate, *Beta-eucaine Lactate* ($C_{15}H_{21}.NO_2.CH_3.CH(OH).COOH$.—A white, non-hygroscopic powder, melting at 155° C. and soluble in water and alcohol. Its solutions are non-irritating and are employed in the same manner as those of betaeucaine hydrochloride.

Eucalyptus Manna. *Australian Manna.*—This substance exudes during the summer months from punctures made in the bark and leaves of the Australian tree, *Eucalyptus viminalis* Labill. (Fam. *Myrtaceæ*). It occurs in small round opaque masses, and is said medicinally to resemble ordinary manna. It contains melitrose. A similar manna is also formed on *Eucalyptus Gunnii* Hook. The "*blue-grass manna*" of Australia occurs on the stems of *Andropogon annulatus* Forsk. (Fam. *Gramineæ.*) The latter contains 75 per cent. of mannite.

Eucatropine, *Eucatropina, Euphthalmine, N. N. R.* 1924, Phenyl-glycolyl-methyl-vinyl-diacetinalkamine hydrochloride. The 1-2-6-6-tetra-methyl-4-mandeloxy-piperidine hydrochloride.—A white granular, odorless powder, permanent in air, soluble in water, alcohol and chloroform. Insoluble in ether. Melting point above 183° C. It is used in ophthalmoscopic examinations in place of atropine.

When instilled into the eye in strengths of 2 to 5 per cent., euphthalmine hydrochloride causes a marked dilatation of the pupil, which begins in about fifteen minutes, reaches its maximum in about one hour, then slowly disappears and the eye completely recovers in about twenty-four hours. According to Jackson (*Ophthalmic Record*, July, 1899), there is a partial but not complete paralysis of accommodation from the 5 per cent. solution of the drug. It is relatively non-irritant to the conjunctiva, although its repeated use may produce conjunctivitis. It is not locally anesthetic. Its value in ophthalmology depends upon the comparatively short duration of the mydriasis and its relatively low toxicity. Mironescu (*Th. M.*, 1905) found that the lethal dose for the rabbit is about one gramme per kilo subcutaneously. The same author also asserts that it differs markedly from atropine in that it slows the pulse instead of accelerating it.

Eucerin.—This is a mixture of 5 parts of an oxy-cholesterin obtained from wool fat with 95 parts of paraffin. As put upon the market it is usually combined with equal parts of water. It is intended as an ointment base and is said to penetrate the skin with great readiness.

Eucodin. *Eucodeine Codeine Brom-methylate. Methyl-codeine Bromide.* $C_{18}H_{21}O_3N(BrCH_3)$.—A crystalline product, melting point 261° C. and soluble in slight proportions in water. *Eucodin* is asserted to stimulate the respiratory center, but allays bronchial irritation and acts as a general analgesic without narcotic action. Eucodin gives a bluish-green color when added to a solution of formin in sulphuric acid. It is employed in *phthisis* and *coughs* in *doses* of one grain (0.065 Gm.) several times a day.

Eugenia Cheken Hook. et Arn. (*Myrtus Cheken* Spreng.) *Cheken. Chequen Arrayan.* (Fam. *Myrtaceæ.*)—The leaves of this Chilian plant have entered commerce under the name of *Chekan leaves.* Weiss (*A. Pharm.*, 1888, p. 226) has found in them: (1) *chekenon*, $C_{40}H_{44}O_8$, a crystalline body; (2) *chekenin*, $C_{12}H_{11}O_3$, in yellowish rhombic tables; (3) *chekenetin*, $C_{11}H_7O_6 + H_2O$, in olive-colored crystals; (4) *cheken-bitter*, an amorphous, very soluble bitter substance. (See *P. J.*, 1889, 782, and Wein, *A. Pharm.*, 1888, 665.) The leaves are used in their native country as a remedy in *chronic respiratory catarrh*, and have been strongly recommended by Murrell and others in *chronic bronchitis.* Their virtues appear to reside in the tannin, and especially in the volatile oil that they contain. The *dose* of the fluidextract is from one to three fluidrachms (3.9–11.6 cc.).

Eugenia Jambolana Lam. (*Syzygium Jambolana* Lam.) *Jambul. Jambol. Rose Apple. Java Plum.*—This is a large tree belonging to the *Myrtaceæ*, growing in East India and also in Queensland; well known on account of its edible fruit. The bark and seeds are employed in medicine. *Jambul bark* is a dense, hard bark, about 1.5 cm. in thickness, of a pinkish-brown or reddish-brown color, with a whitish-gray mottled cork or thick bark, the inner surface is of a somewhat silky luster, frequently coarsely marked by waving lines or ridges; the fresh fracture varies from pinkish or purplish to fawn color, sometimes distinctly but shortly fibrous, more commonly absolutely abrupt. The taste is somewhat bitter, astringent, after a time distinctly pungent. The bark contains a resin, tannin, and gallic acid. *Jambul seeds* are grayish-black, or blackish-gray, being abruptly truncated at the base, above rounded or dome-shaped. They are from 1 to 2.5 cm. long, and 8 to 12 mm. broad; so hard and dense that they cannot be chewed, and are almost tasteless. The analysis of the seeds by Thomas Christy yielded a trace of volatile oil, but no other characteristic products. Power and Callan (*P. J.*, 1913, 245) found in these seeds a phenolic substance, *jambulol*, $C_{16}H_3O_4(OH)_5$, which is identical with *ellagic acid.* An alkaloid *jambosine*, melting point 77° C., is also present.

In 1886 Binz announced that the exhibition of jambul to dogs who were glycosuric as the result of the administration of phloridzin greatly reduced the excretion of sugar. In 1888 Christy found that jambul increased the activity of the diastasic enzyme. As a result of these studies the drug was at one time used in the treatment of *diabetes* but as it is to-day generally conceded that phloridzin glycosuria is due to the action of the poison upon the kidney and is not allied to true diabetes, the theoretical foundation for the use of jambul falls to the ground, and practically it has failed to establish its value. In India the drug has been used for its astringent and stimulating effect in *diarrhea.* The *dose* of the fluidextract usually recommended is ten minims (0.6 cc.); but according to von Noorden (*Deutsche Praxis*, 1901) half a fluidounce (15 cc.) of the fluidextract should be taken in eight fluidounces (240 cc.) of hot water, one hour before breakfast and late in the evening.

Jamrosin is a proprietary preparation asserted to be the fluidextract of jambul. It is alleged to possess marked remedial qualities in the treatment of *diabetes*.

Euguform.—*Acetylized methylene diguaiacol* is obtained by the action of formaldehyde upon guaiacol and subsequent acetylization. It is a white, almost odorless, dust-like and amorphous powder, insoluble in water. It has been recommended by Ciesielski as a substitute for orthoform, as a dusting powder or in the form of a 2 to 10 per cent. ointment. A 50 per cent. solution of *euguform* in acetone is marketed as *neo-euguform*. (*Derm. Cb.*, 1901, No. 6; see also *M. R.*, 1912.)

Euphorbia. *Spurge. Wild Ipecac. Wild Hippo. Euphorbe*, Fr. *Wolfsmilch*, G.—The genus *Euphorbia* (Fam. *Euphorbiaceæ*) contains numerous species which contain a white milk-juice characterized by containing dumbbell-shaped starch grains. They are herbaceous or shrubby, with or without leaves, and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, like those of the cactus. Their flowers are monoecious and placed within a cup-shaped, 4- to 5-lobed involucre. They nearly all afford products which act powerfully as emetics and cathartics, and in overdoses occasion dangerous if not fatal prostration, with symptoms of inflammation of the gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when applied to it. The U. S. Pharmacopœia formerly recognized the indigenous species *E. corollata* L. (*Flowering Spurge*) and *E. Ipecacuanhæ* L. (*Wild Ipecac*). In a full dose the root of *E. corollata* L. acts as an emetic and cathartic and in smaller doses is a nauseating diaphoretic and expectorant. It is, however, too harsh and uncertain in its action for practical use, and has passed entirely out of vogue. The *dose* of the dried root as an emetic is from ten to twenty grains (0.65–1.3 Gm.), as a cathartic from three to ten grains (0.2–0.65 Gm.). The recent root, bruised and applied to the skin, produces vesication. C. Petzolt (*A. J. P.*, 1873) found in the root of *E. Ipecacuanhæ* a dark resin which in half grain (0.032 Gm.) doses produced watery stools, and in one and a half or two grain (0.096 or 0.13 Gm.) doses nausea and vomiting. It gave no evidence of the presence of an alkaloid. The medicinal properties of *E. Ipecacuanhæ* resemble those of *E. corollata*, though the former is said to be somewhat milder.

The indigenous *E. Preslii* Guss. (*E. hypericifolia* Gray) and *E. maculata* L. according to Zollickoffer is valuable in *dysentery, diarrhea, menorrhagia*, and *leucorrhea*. (See 16th ed., *U. S. D.*, also *A. J. M. S.*, xi.) The juice of *Euphorbia Drummondii* Boiss. is said in Australia to kill annually a great many sheep and cattle, and in 1886 John Reid (*Australasian Med. Gaz.*, No. 61) announced the discovery in it of a new anesthetic alkaloid, *drummine*, which he obtained in colorless crystals almost insoluble in ether, but freely soluble in chloroform and in water. The report of Alexander Ogsden (*B. M. J.*, Feb., 1887) throws, however, very grave doubts upon the anesthetic power of this new alkaloid. *Euphorbia cremocarpus* Auct. of the Pacific Coast is employed for the purpose of poisoning fish in still pools and streams, and is said to contain a volatile oil, besides acid and resins. (See *Proc. California Coll. Pharm.*, 1885.) The oil of *E. Lathyris* L. is stated to physiologically resemble croton oil. (*Proc. A. Ph. A.*, xxvi, 305.)

The *E. heterodoxa* Muell.-Arg., *alveloz* or *aveloz*, a Brazilian species, has been used with asserted extraordinary advantage against *cancerous* and *syphilitic ulcers*. It is a powerful irritant, and even mild caustic. The milky juice, preserved with salicylic acid, or a resin obtained by precipitating with water is employed. The ointment of the resin may be made 3 parts in 100 with vaseline. For further information concerning various euphorbia species which have been used in medicine, see *U. S. D.*, 19th edition, p. 1484.

The concrete resinous milk-juice of *Euphorbia resinifera* Berg, a fleshy cactus-like plant growing in Morocco, was formerly recognized by the German Pharmacopœia under the name of *Euphorbium*, P. G. (*Euphorbiumharz.*) The plant is characterized by having fleshy, quadrangular stems and branches which bear small scale-like leaves supported by two thorny stipules, small flowers and 3-carpelled fruits.

Laticiferous vessels containing a milky-juice occur in cortex and pith. The branches are wounded during the rainy seasons and the milky exudation is collected and dried by Arabs who bring it to Morocco. It is exported from Mogadore. The inspissated juice occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical apertures, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the mass. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable, the color light yellowish or reddish; the odor scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The color of the powder is yellowish. The sp. gr. of *euphorbium* is 1.124. Triturated with water it renders the liquid milky and is partially dissolved. Alcohol dissolves it about 60 per cent., forming a yellowish tincture, which becomes milky on the addition of water. The most abundant constituent is resin, and the remainder consists chiefly of wax and calcium malate. The resin is excessively acrid, is soluble in alcohol, and, when exposed to heat, melts, takes fire and burns with a brilliant flame, diffusing an agreeable odor. Flückiger (*A. J. P.*, 1868) also found a substance analogous to lactucon, which he named *euphorbon*, $C_{15}H_{24}O$. Tschirch and Paul made an investigation of euphorbium and found *euphorbic acid*, $C_{24}H_{30}O_6$, *euphorbin*, $C_{30}H_{48}O$, malic acid and a bitter, and also an acrid principle. (*A. Pharm.*, 1905, 249.)

Euphorbium taken internally is a very irritant emetic and cathartic, and in large doses acts as a violent gastro-intestinal irritant poison. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended by incessant sneezing and sometimes bloody discharges. Persons who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Externally applied it inflames the skin, often producing vesication. It enters into some epispastic preparations, and is especially employed in veterinary practice as a vesicant. See also *Euphorbia pilulifera*, Part I.

Euphorin. *Æthylis Phenylcarbamas. Phenol—Urethane, Phenylcarbamic Acid Ethyl Ester.*

UNIVERSITY OF ILLINOIS
LIBRARY-CHEMISTRY

$(C_6H_5NH)CO(OC_2H_5)$.—It is in the form of colorless needles or a white powder, melting at 50° to 51° C., having a faint aromatic odor and taste, almost insoluble in water, readily soluble in diluted alcohol, alcohol or ether. It is used as an anodyne and antipyretic in *doses* of eight to fifteen grains (0.5–1.0 Gm.); also externally in *skin diseases, ulcers,* etc., either as a dusting powder or in an ointment.

Euphrasia. *E. officinalis* L. *Eyebright. Eyewort. Euphraise,* Fr. *Augentrost,* G. (Fam. *Scrophulariaceæ.*)—A small annual plant, native of Europe, without odor, and of a bitter, astringent taste. Enz (*Viertelj. f. Prakt. Pharm.*, viii, 175) obtained a little volatile oil, an acrid and bitter principle, mannite and glucose, and a tannic acid. The name "eyewort" so frequently ascribed to this drug, is derived from the practice of using it in eye affections in older medicine. It is used on the continent to-day as an astringent tonic in the treatment of *jaundice.* G. M. Garland (*A. J. P.*, 1890) states that ten minims (0.6 cc.) of a concentrated tincture every two hours is a specific in acute *nasal catarrh.*

Eupyrine. *Para-phenetidine-vanillin-ethyl-carbonate.*

$$C_6H_4\begin{matrix}OC_2H_5\\ N{=}CH.C_6H_3\end{matrix}\begin{matrix}O.COOC_2H_5.\\ OCH_3\end{matrix}$$

This substance occurs in pale yellow, tasteless needles, with a vanillin odor melting at 87° to 88° C., insoluble in water, sparingly so in cold alcohol, ether, and chloroform, but very soluble in these solvents when warmed. It forms salts by combination with a few acids, and is decomposed by some other acids and by all alkalies. It has been brought forward by Overlach (*Cb. I. M.*, xxi, 1900) as an antipyretic, who found that half an ounce of it causes no serious symptoms in dogs. He claims that it produces a gradual but marked fall of the temperature, accompanied by a sense of euphoria rather than of depression. In neuralgia he found that it was without influence. Porges has confirmed the statements of Overlach. The remedy is stated to be of special value in the young and the aged. *Dose,* twenty to thirty grains (1.3–2.0 Gm.).

Euresol. *N. N. R.* 1924. *Resorcin monoacetate. Monoacetyl Resorcinol.* $C_6H_4(OH)OCOCH_3$.—A viscid honey-like liquid, boiling at 283° C. It is made by heating resorcinol with glacial acetic acid. It is used as a substitute for resorcinol in the treatment of *seborrhea, sycosis* and other diseases of the skin. According to Joseph and Vieth (*Derm. Cb.*, 1905), it has the advantage over resorcinol in exercising a deeper influence, and being less irritant. It may be employed in strengths of from 5 to 10 per cent.

Eurobin. *Chrysarobin Triacetate.*—This is a yellowish-red powder, *triacetyl chrysarobin,* used as a substitute for chrysarobin; it is soluble in chloroform, acetone, and ether, insoluble in water. It acts like chrysarobin on the skin, but is more powerful. Kromayer commends it applied as a paint, according to the following formula: Saligallol, 5 to 10 parts; eurobin, 1 to 20 parts; acetone, to make 100 parts. *Lenirobin,* the tetracetyl derivative, *chrysarobin tetra-acetate,* is less irritant than chrysarobin, and has the special advantage of not staining the linen.

Neorobin is made by dissolving chrysarobin in glacial acetic acid and subsequent reduction with metallic tin. It is stated, however, that it is neither a complex acetate nor a tin compound but a primary reduction product. It dissolves in acetone with a golden yellow solution instead of dark red as does chrysarobin. According to Masucci and Slothower (*J. A. Ph. A.*, 1923, xii, 335) it is a more active reducing agent than chrysarobin.

All these preparations are used as local applications in *skin diseases,* especially *psoriasis.*

Europhen. *Di-isobutyl-ortho-cresol-iodide.* $C_6H_3(C_4H_9)\ (CH_3)\ (OI)C_6H_2(CH_3){:}O\ (.C_4H_9)$.—This is a yellow amorphous powder, of a specific aromatic odor, which has been proposed as a substitute for iodoform. It is asserted that it is five times lighter than iodoform, and can be used in much larger bulk; that it is equally efficacious with iodoform; also that it is decomposed more slowly than iodoform, and is, therefore, less poisonous. (See *Ph. Ztg.*, July, 1891; also *Th. M.*, July, 1891.) *Europhen* is made by the action of iodine upon isobutylorthocresol in alkaline solution. It occurs as a fine, soft, amorphous powder, light yellow, tasteless, and having but a faint odor. It is soluble in ether, chloroform, collodion, alcohol, and fixed oils; insoluble in water and glycerin; melting at 110° C. Its solution undergoes decomposition when exposed to light or heat.

Europhen contains about 28.1 per cent. of iodine, which element is slowly liberated from its alcoholic and ethereal solutions. It is incompatible with metallic oxides and mercurial salts, and undergoes slight change in the presence of organic matter. Taken internally it is said to pass out in great part from the alimentary canal with the feces unchanged, though some absorption takes place. It is asserted that it is non-toxic, two or three drachms (7.7–11.6 Gm.) having been given to dogs and fifteen grains (1 Gm.) to human beings without effect. As an antibacterial it is affirmed to be about equivalent to iodoform. (*Revue Méd. de l'Est,* Feb., 1892.)

It has been used by a number of clinicians with asserted good results as a local application in *chancres, syphilitic ulcers, burns, psoriasis, eczema, lupus,* and various *skin diseases.* It may be applied either as a dusting powder or in an ointment varying in strength from 1 to 10 per cent. It has also been employed in *rhinitis, laryngeal tuberculosis,* and other inflammatory disorders of the preliminary air-passages. Internally it has been used, especially hypodermically, dissolved in oil, in *constitutional syphilis,* with not very encouraging results. *Dose,* one-half to one and one-half grains (0.032–0.096 Gm.).

Euscopol. $C_{17}H_{21}O_4N.HBr$.—An optically inactive scopolamine hydrobromide. (See *Scopolaminæ Hydrobromidum,* Part I.)

Evodia.—Several species of this rutaceous genus are stated to have medicinal properties. *Evodia febrifuga* St. Hil. (*Esenbechia febrifuga* A. Juss.) of Brazil is astringent and tonic, *E. meliæfolia* Benth. of Japan contains berberine, while *E. longifolia* A. Rich. of the Fiji Islands is used to prevent abortion. The allied plant *E. Rutaecarpa* yielded to Asahina (*J. P. C.*, 1916, xiv, p. 54) two alkaloids—*evodiamine* and *rutaecarpine.*

Exalgine. *Methylacetanilide.* $C_6H_5N(CH_3)$-$COCH_3$ or $C_9H_{11}NO$.—This substance, which was discovered by Brigonnet, is one of the three isomeric methyl derivatives of acetanilide (*C. R. A. S.*, cviii, 571), and is made by warming together monomethylaniline and acetylchloride. It occurs in needles, or in long tablet-like crystals, sparingly soluble in cold water, quite soluble in hot water, and readily soluble in very dilute alcohol; it fuses at 101° C. and boils between 240° and 250° C. without decomposition. The hot aqueous solution is said by Upton to retain most of its exalgine on cooling.

According to Brigonnet, hypodermic injections of exalgine produce in the lower animals violent epileptiform convulsions, profuse salivation, cyanosis, disturbance of breathing, fall of temperature, and methemoglobinemia. When given to man in full, non-poisonous doses, it produces some slight amblyopia, vertigo accompanied in some patients by vomiting, tinnitus aurium, headache, drowsiness, and vasomotor disturbances, such as sweating. After toxic doses, dyspnea, cyanosis, dilated pupils, paresis, heart weakness, and convulsions have been noted, but we know of no fatal result; in a boy fourteen years old two doses of three grains each produced most alarming symptoms.

Therapeutically, exalgine has been used as an analgesic and antispasmodic. According to Moncorvo, it is very well borne in children; he has used it extensively in *chorea*, *polyuria*, and for the relief of *pain*. He believes that its analgesic effect is at least five times as strong as that of antipyrine. *Dose*, for an adult, three to five grains (0.2 to 0.32 Gm.), not more than twelve grains to be given in twenty-four hours.

Exodin.—This is stated to be a hexamethylester of rufigallic acid. *Rufigallic acid* or *rufigallol*, which is manufactured by heating gallic acid with five times its weight of strong sulphuric acid, is a hexahydroxy-anthraquinone. Exodin, therefore, bears some chemical relation to the principles found in the vegetable cathartics. It occurs as a yellow, odorless, tasteless powder, insoluble in water. It has been used with satisfactory results by a number of clinicians as a cathartic, especially in chronic constipation. It is claimed for it that it is non-irritant and does not produce after constipation. The *dose* is from fifteen to thirty grains (1 to 2 Gm.), usually given in the form of tablets.

Fabiana. *Fabiana imbricata* Ruiz and Pavon. *Pichi.* (Fam. *Solanaceæ.*)—This is a small shrub growing in Bolivia, Peru, Chili and the Argentine Republic. The plant somewhat resembles a juniper. The branches are brownish-gray and about 5 mm. in diameter; the wood is yellowish and tough; leaves scale-like, about 1 mm. in length, closely imbricated and bluish-green; the flowers are about 12 mm. in length and possess a white or purplish corolla; the fruit is a capsule containing a few sub-globular seeds. The odor of the drug is aromatic and the taste bitter and terebinthinate. For microscopic structure, see *Ph. Ztschr. f. Russland*, 1891, No. 44; *Apoth. Ztg.*, 1892, p. 22.

A. B. Lyons obtained from it a fluorescent body resembling æsculin, a neutral crystalline principle, some volatile oil, resin, and apparently traces of an alkaloid. (*A. J. P.*, 1886, 65.) Henry Trimble and J. M. Schroeter (*A. J. P.*, 1889, 407) considered the crystalline principle to be a resin, and gave it the formula $(C_{18}H_{31}O_2)x$. H. Kunz-Krause (*A. J. P.*, 1900, p. 80) made a full study of pichi and found a tannin which he named *fabiana-tannoid*, a fluorescent substance proven to be *chrysatropic acid* (*β-methyl æsculetin*), $C_9H_5(CH_3)O_4$, while no alkaloids are present, the sole basic principle being choline. The volatile oil he names *fabianol* and gives it the formula $C_{54}H_{90}O_2$. The resin he calls *fabiana resin* and gives to it the formula $(C_{18}H_{30}O_2)_3$. The resin appears in microscopical crystals, melting at 280° C. The tannin proved to be like caffetannic acid.

Pichi appears to belong with the terebinthinate diuretics and has been used to a considerable extent in the treatment of both acute and chronic *cystitis* and in gonorrheal *prostatitis*. It was formerly attributed with cholagogue properties. It is somewhat irritating and must be used very cautiously in cases of inflammatory conditions of the kidney. The solid extract may be used in the *dose* of from two to ten grains (0.13–0.65 Gm.); the fluidextract, in the *dose* of from ten to forty minims (0.6–2.5 cc.).

Fanghi di Sclofani.—This is a light yellowish fine powder of volcanic origin, consisting chiefly of sulphur and small quantities of iron, manganese, calcium, etc., the sulphur being in an exceedingly fine powder. It is highly praised by Otto v. Fleischl as a remedy in *acne rosacea*. Two or three grains (0.13 or 0.2 Gm.) of the powder are mixed with a teaspoonful (4 cc.) of water and the opaque mixture applied with the finger on going to bed and allowed to dry on the part.

Ferioben. *Ferro-sajodin. N. N. R.* 1924. *Basic ferric iodo behenate* (approximately $(C_{21}H_{42}I\text{-}COO)_2(OH)Fe$) representing at least 5 per cent. of iron and 25 per cent. of iodine. It exhibits the action of iodide and of iron and is claimed to be more stable and palatable than ferrous iodide. *Dose*, eight to fifteen grains (0.5–1 Gm.).

Ferment Diagnosticum. *N. N. R.* 1924. *Solution of Glycyltryptophan.*—This solution is used in determining the presence of a proteolytic ferment on account of its being split up by such ferments with the liberation of *tryptophan*, which may readily be detected.

Ferratin. *Sodii Ferri Albumas.*—This is a light brown powder containing from 6 to 8 per cent. of iron in a form soluble in alkaline liquids. It is an albuminous compound, originally prepared by Schmiedeberg from the liver of the hog, and believed to be the natural compound of iron as it exists in the system. It is now made by the reaction of the albumin with a double tartrate of iron and an alkali. It is almost insoluble in water, soluble in alkalies, and contains 7 per cent. of iron in organic compounds. The iron is firmly united to the albumen molecule so that ammonium sulphide does not react at once. A solution of ferratin has also been put upon the market under the name of *ferratose*.

Ferratin may be given in *doses* of from three to five grains (0.2–0.32 Gm.) three times a day. It appears to be capable of acting as a chalybeate, but there is no sufficient reason for believing it to be superior to the older preparations of iron.

Ferratogen. *Ferri Nucleinas.*—This substance is obtained by the cultivation of yeast on a ferruginous nutritive medium and subsequent extraction. It occurs as a grayish-white or yellow powder, insoluble in water or gastric juice, but believed to be dissolved by pancreatic fluids. The content of iron is claimed to be slightly over 1 per cent. It has been recommended by Cloetta in *chlorosis* when the stomach is delicate. *Dose*, five to ten grains (0.32–0.65 Gm.).

Ferric Albuminate. *Ferri Albuminas.*—This preparation has come into some prominence, more particularly in Europe, on account of its asserted advantages over various other compounds of iron, Démarquay, Chrisnard, and others recommending its employment in *chlorosis* and *anemia*, as being very readily absorbed. Various methods have been proposed for preparing either the solution or dry salt. C. L. Diehl, after a careful review of these processes, offers the following: 4 troyounces of white of eggs are diluted with 8 fluidounces of water; 65 minims of official solution of ferric chloride diluted with 4 fluidounces of water are added, and the solution filtered. The filtrate is now mixed with 10 fluidounces of a saturated solution of sodium chloride, the precipitate collected on a wet muslin strainer, washed with a mixture of 1 volume of the saturated solution of sodium chloride and 3 volumes of water, until the washings give but a faint reaction for iron. The washed ferric albuminate is, after draining, powerfully pressed to get it as dry as possible, and then exposed to a dry atmosphere, and finally powdered. This salt contains the equivalent of 5 per cent. of ferric oxide, or 10 per cent. of ferric chloride. (For other processes, see *A. J. P.*, 1880, 177.) As thus obtained, ferric albuminate is a cinnamon-brown powder, having a slight saline taste, soluble in water, particularly if slightly acidulated with hydrochloric acid. It is best administered in *doses* of from twenty to thirty grains (1.3–2.0 Gm.) in simple aqueous solution, which should be freshly prepared. See *Liquor Ferri Albuminati, N. F.* (Part III). For method of preparing *iron and potassium albuminate*, and *iron and sodium albuminate*, see 16th ed., *U. S. D.*

Ferric Ammonium Chloride. *Iron Ammoniated. Ammoniated Iron. Ferrum Ammoniatum. Ammonio-chloride of Iron. Ammonii et Ferri Chloridum. Ammonium Chloratum Ferratum. Sel Ammoniac Martial*, Fr. *Eisensalmiak*, G.—This drug was formerly recognized both by the U. S. and London Pharmacopœias, which contained formulas for its preparation. (See *U. S. D.*, 15th edition, 1568.) There is no reason to believe that the ferric chloride and ammonium chloride are chemically combined in the preparation. According to Phillips, they are in the proportion of 15 parts of the iron to 85 of the ammonium salt.

Ammoniated iron is in crystalline grains of a fine reddish-orange color, and a sharp, styptic, saline taste. It is entirely soluble in water and diluted alcohol, is deliquescent, and should be kept in well-stoppered bottles. As procured by sublimation (*Flores martiales, Ens martis*), it is of a yellow color and feeble odor. It unites aperient with chalybeate properties, and is said to have been used with advantage in *amenorrhea, epilepsy, scrofula, rickets*, etc.; but it is at best uncertain, and is now very seldom prescribed. *Dose*, from four to twelve grains (0.26–0.78 Gm.).

Ferric Ammonium Sulphate. *Ferri et Ammonii Sulphas. U. S. VIII. Iron and Ammonium Sulphate. Ammonio-Ferric Alum. Iron Ammonium Alum. Ferrum Sulfuricum Oxydatum Ammoniatum. Ferrum Ammonio-Sulphuricum. Ferri Ammonio-Sulphas. Alumen Ammoniacale ferricum. Iron Alum. Sulfate de Fer et d'Ammoniaque. Alun de Fer ammoniacal.* Fr. *Schwefelsaures Eisenoxyd-Ammonium. Ammoniakalischer Eisenalaun*, G. $FeNH_4(SO_4)_2 + 12H_2O = 482.21$.—The *U. S.*, 1870, gave the following process for this salt: "Take of Solution of Tersulphate of Iron *two pints;* Sulphate of Ammonium *four troy-ounces and a half.* Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air." *U. S.*, 1870.

Ammonio-ferric alum is in "pale violet, octahedral crystals, without odor, and having an acid, styptic taste; efflorescent on exposure to the air. Soluble in 2.7 parts of water at 25° C. and in 0.8 part of boiling water; insoluble in alcohol. When strongly heated, the crystals fuse, lose their water of crystallization, expand, and finally leave a pale brown residue. The aqueous solution of the salt has an acid reaction upon blue litmus paper, and yields with potassium ferrocyanide T.S. a blue precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid." *U. S. VIII.* According to H. Rose, the pure salt is white, and gives a colored solution with water, in consequence of the formation of a basic ferruginous salt. This decomposition is prevented by dissolving it in diluted sulphuric acid, when the solution is colorless. Instead of ammonium sulphate, potassium sulphate may be employed with the solution of ferric tersulphate, in which case a potassium iron-alum is produced, called *potassio-ferric alum*, which has all the properties, physical and remedial, of the ammonio-ferric salt, and the two appear to have been indiscriminately used.

The iron-alum is an active astringent and was used chiefly as a local application in passive *leucorrheas*, and as a styptic.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

Ferric Ammonium Tartrate—*Iron and Ammonium Tartrate. Ferri et Ammonii Tartras. U. S. VIII. Ferrum Tartaricum Ammoniatum. Ammonio-Tartrate of Iron. Tartrate Ferrico-ammonique*, Fr. Cod., Fr. *Weinsaures Eisenoxyd-Ammonium*, G.—This iron scale-salt should contain Iron and Ammonium Tartrate corresponding in amount to not less than 13 per cent. of metallic iron.

The process of the U. S. P., 1890, for preparing iron and ammonium tartrate was: "Solution of Ferric Sulphate, *one hundred cc.;* Tartaric Acid, *twenty-nine grammes;* Distilled Water, *two hundred cc.;* Ammonia Water, Water, each, *a sufficient quantity.* To *one hundred and ten cc.* of Ammonia Water, previously diluted with *two hundred and fifty cc.* of cold Water, add with constant stirring, the Solution of Ferric Sulphate, previously diluted with *thirteen hundred cc.* of cold Water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about *fifteen hundred cc.* of cold Water, again draw off the clear liquid, and repeat the washing with Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Dissolve one-half of the Tartaric Acid in the Distilled Water, neutralize the solution exactly with Ammonia Water, then add the other half of the Tartaric Acid, and dissolve it by the application of a gentle heat. Now add the moist ferric hydrate, in successive portions, stirring constantly, and continue the heat, which should not exceed 60° C., until the hydrate is dissolved. Filter the solution while hot, evaporate it in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*, 1890.

Theoretically this process should yield a double salt consisting of one molecule of tartaric acid and two molecules of base, one of ammonia and the other of ferric oxide $2(FeO)NH_4.C_4H_4O_6.3H_2O$. It is hardly probable that the salt has exactly this chemical composition, as the scaled salts cannot be said to be definite compounds.

This compound is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol." *U. S. VIII.* For further tests for this salt see *U. S. D.*, 20th edition, p. 1445. *Dose*, as a mild chalybeate, from five to ten grains (0.32–0.65 Gm.).

Ferric Arsenate. $Fe_3(AsO_4)_2 + 6H_2O$.—*Iron arsenate* is a green, amorphous powder, insoluble in water, but soluble in the presence of dilute mineral acids. It is used as an insecticide especially for agricultural purposes, and may be employed in strengths of from 0.1 to 0.2 per cent.

Ferric Arsenite. *Arsenite of Iron. Iron Arsenite.* $4Fe_2O_3As_2O_3 + 5H_2O$.—This is a brownish-yellow powder soluble in acids and insoluble in water, but the combination with ammonium citrate is soluble and has been put upon the market under the name of *ammoniated citro-arsenite* of iron. *Ferr-arseno-citras Ammoniatus.* This represents about 16 per cent. of iron and 1.4 per cent. of arsenous acid. It is used in the treatment of various forms of *anemia* but is especially commended in *pellagra.* It has been highly commended by Valvassori and Peroni (see *M. R.*, 1900) for the hypodermic treatment of *malaria*, especially in children. It may be given either by the mouth or hypodermically. The *dose* for the latter purpose is from one-half to one grain (0.032 to 0.065 Gm.) every second or third day.

Ferric Benzoate. *Ferri Benzoas. Ferrum Benzoicum. Eisenbenzoat, Ferribenzoat,* G.—$Fe_2(C_7H_5O_2)_6 + nH_2O$.—This is made by precipitating a solution of ammonium benzoate with a diluted solution of ferric chloride. The precipitate, after being washed, is dried at a temperature not above 30° C., protected from light. A brownish-red, odorless, tasteless powder, insoluble in water. When freshly prepared it is soluble in cod liver oil.

Ferric Citrate. *Ferri Citras. U. S. VIII. Iron Citrate. Citras Ferricus. Citrate Ferrique,* Fr. *Ferrum Citricum Oxydatum,* P. G. *Citronensaures Eisenoxyd, Eisencitrat,* G. *Citrato di ferro,* It. *Citrato ferrico,* Sp.—"It should contain Ferric Citrate corresponding in amount to not less than 16 per cent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." *U. S. VIII.* This preparation is made by evaporating a solution of ferric citrate. The latter was dropped from the U. S. P., but is now official in the National Formulary IV (see Part III).

Ferric Citrate is not a definite chemical salt, but a compound containing ferric citrate, to which the following formula has been assigned: $Fe_2(C_6H_5O_7)_2.6H_2O$. The U. S. P. required not less than 16 per cent. of metallic iron. It is important, in making it, that an excess of citric acid be avoided, and the ferric hydroxide be thoroughly washed to free it from sulphates, otherwise brilliant scales will not be formed.

Ferric citrate is in "thin, transparent, garnet-red scales, without odor, and having a slightly ferruginous taste. Slowly but completely soluble in water at 5° C., and readily soluble in hot water, but diminishing in solubility with age; insoluble in alcohol." *U. S. VIII.* For further tests of this salt see *U. S. D.*, 20th ed., p. 1387.

Ferric citrate is an excellent chalybeate, nearly free from astringency and is preferably given in solution. Bullock (*J. A. M. A.*, 1911, lvii, p. 1428) has had most excellent results in the *anemia* of *tuberculosis* from the hypodermic use of this salt. He injected one grain (0.065 Gm.) directly into the muscle substance daily. (See also *Ferri et Ammonii Citras*, Part I.)

Dose, by mouth, three to ten grains (0.2–0.65 Gm.).

Ferric Hydroxide. *Ferri Hydroxidum. Ferri Oxidum Hydratum. Ferric Hydrate. Hydrated Oxide of Iron.* $Fe(OH)_3 = 106.86$. *Ferri Peroxidum. Ferri Sesquioxidum. Ferri Oxidum Rubrum. Hydrous Peroxide of Iron. Ferric Oxyhydrate. Ferrugo. Hydrated Peroxide of Iron. Hydrated Sesquioxide of Iron. Moist Peroxide of Iron. Hydras Ferricus. Oxyde (sesqui) de fer Bihydraté,* Fr. Cod. *Sesquioxide (Péroxide) de Fer hydraté humide, Hydrate de Péroxyde de Fer gélatineux,* Fr. *Eisenoxydhydrat, Gegengift der Arsenigensaure,* G. *Ossido ferrico idrato,* It. *Hidrato ferrico gelatinoso,* Sp.—Under the name of *Magma Ferri Hydroxidi* the N. F. recognizes a mixture containing the washed precipitate formed by mixing a solution of ferric sulphate with ammonia water, which is essentially the same as the preparation recognized by the U. S. VIII under the name of *Ferri Hydroxidum.* "This is a brownish-red magma wholly soluble in hydrochloric acid without effervescence." *U. S. VIII.* In preparing this it is important that the solution of ferrous sulphate be poured into the ammonia solution and not vice versa as when the ammonia water is added to the iron solution there is formed a clotty precipitate of uncertain composition.

As prepared by the old process of the Dublin Pharmacopœia, in which it was heated to redness, it lost the second molecule of water, and became the anhydrous sesquioxide (Fe_2O_3), identical with the *colcothar* of commerce. This is less easily soluble in acids, and altogether without effect as an antidote. Kept for some time in the moist state, it loses half its combined water, and becomes less soluble in acids and less efficient as an antidote. Hirsch has given some useful details in making precipitated ferric oxide upon a comparatively large scale, in *Am. Drug.*, 1884, 66.

The *monohydrated sesquioxide* is a reddish-brown, tasteless, insoluble powder, differing from colcothar in containing a molecule of water. Hence, "heated to dull redness in a test-tube it yields about 10 per cent. of moisture." *Br.*, 1885. It should not be deliquescent, and should dissolve entirely in hydrochloric acid without effervescence. Its solution in diluted hydrochloric acid yields a copious blue precipitate with potassium ferrocyanide, but none with the ferricyanide, showing that it contains ferric oxide but no ferrous oxide. Dawies states that if the hydrated oxide recently prepared be kept for four days in boiling water it loses a large proportion of its water, containing at the end of that time only 5.77 per cent.; the larger portion of the oxide has, therefore, become dehydrated, and the same thing happens at a lower temperature, 41.1° C., as in two or three months it becomes of a brick-red color, and is but slightly soluble in nitric acid. (*J. P. C.*, 4e sér., iv, 400.) Ferric Hydroxide is not an eligible ferruginous medicine; its sole therapeutic use is as an antidote to arsenic and for this purpose it is inferior to the pharmacopœial *Ferri hydroxidum cum magnesii oxido.* It was an ingredient in the *Emplastrum Ferri* (*iron plaster*) and the *Trochisci Ferri, U. S.*, 1890. The former Dublin *rubigo ferri*, or *rust of iron*, formed by exposing moistened iron wire to the air until converted into rust, is essentially the sesquioxide, containing a little ferric carbonate, and does not differ materially from the iron subcarbonate formerly official.

Ferric Oxide, Magnetic. *Ferri Oxidum Magneticum. Magnetic Iron Oxide. Martial Ethiops. Ferrum Oxydatum Magneticum. Oxydum Ferroso-Ferricum. Black Iron Oxide. Oxyde de Fer noir* (*magnétique*), *Oxyde ferroso-ferrique*, Fr. *Magneteisen, Eisenoxyd-Oxydul*, G. $Fe_3O_3(OH)_2$.—The artificial magnetic iron oxide is a brownish-black powder, without taste, and strongly magnetic. It dissolves without effervescence in hydrochloric acid diluted with half its bulk of water, and the solution gives a blue precipitate both with the potassium ferrocyanide and the potassium ferricyanide, showing the presence of ferrous and ferric oxide. *Dose*, from five to twenty grains (0.32–1.3 Gm.).

Scales of iron (*ferri squamæ*) were formerly official with the Dublin College under the name of black oxide. They were prepared from the scales found at the blacksmith's anvil, by washing them with water, separating them from impurities by means of a magnet, and reducing them to a fine powder. They are of variable composition, being mixtures of the two oxides of iron with metallic iron.

The magnetic iron stone has been introduced as a substitute for bismuth salts in röntgenological examination of the intestinal tract. Alexander (*D. M. W.*, 1909, p. 877) especially recommends a mixture of iron oxide with cocoa and milk sugar, known as *diaphanit.*

Ferric Salicylate. *Ferri Salicylas. Ferrum Salicylicum. Ferrisalicylat*, G.—Made by adding sodium salicylate to a concentrated solution of ferric chloride. The violet-colored precipitate, when washed and dried, forms a brown mass or powder insoluble in water. It is sometimes used as a tonic and antirheumatic in *doses* of from three to ten grains (0.2–0.65 Gm.). The N. F. recognizes a solution containing iron salicylate (see *Liquor Ferri Salicylatis*).

Ferric Subcarbonate. *Ferri Subcarbonas. U. S.* 1870. *Iron Subcarbonate. Red Oxide of Iron. Precipitated Carbonate of Iron. Aperitive Saffron of Mars.*—Ferric carbonate is a reddish-brown powder, of a disagreeable slightly styptic taste, insoluble in water, and not readily dissolved by any acid except hydrochloric, with which it effervesces slightly. When of a bright red color it should be rejected, as this color shows that it has been injured by exposure to heat. After precipitation from its hydrochloric solution by ammonia or potassium hydroxide, either of which throws down ferric oxide, the supernatant liquor should give no indications of containing any metal in solution by the test of hydrogen sulphide or potassium ferrocyanide. It is incompatible with acids and acidulous salts. In composition it is a hydrated ferric oxide containing a little ferrous carbonate. By exposure to a red heat, it absorbs oxygen and loses water and carbon dioxide, being converted into the *astringent saffron of Mars* of the French Codex.

Ferric carbonate is a rather feeble ferruginous tonic, nearly free from astringency. It has been especially commended in *neuralgia* in doses of a teaspoonful. *Dose*, five grains (0.32 Gm.).

Ferric Magnesium Citrate. *Iron and Magnesium Citrate. Ferri et Magnesii Citras.*—This double salt, introduced by Van der Corput, is made by dissolving two ounces of freshly precipitated ferric hydroxide in a moderately heated solution of three ounces of citric acid, and saturating the liquor with magnesium carbonate. The solution, after filtration, is evaporated by means of a water bath to a syrupy consistence, and spread on glass to dry in scales. Three and a quarter ounces of ferrous sulphate will furnish by decomposition the necessary hydroxide for three ounces of the acid. This salt is in transparent, greenish-yellow scales, having a slightly ferruginous, somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. *Dose*, from five to ten grains (0.32–0.65 Gm.).

Ferric Strychnine Citrate, Iron and Strychnine Citrate. *Ferri et Strychninæ Citras. U. S. VIII. Citrate de Fer et de Strychnine*, Fr. *Citronensaures Eisen-Strychnin*, G.—"It should contain not less than 0.9 nor more than 1 per cent. of strychnine, and ferric citrate corresponding in amount to not less than 16 per cent. of metallic iron. It should be kept in well-stoppered bottles, protected from light." *U. S. VIII.*

The process for this preparation of the U. S. P., 1890, is as follows: "Iron and Ammonium Citrate, *ninety-eight grammes;* Strychnine, *one gramme;* Citric Acid, *one gramme;* Distilled Water, *one hundred and twenty cubic centimeters*, to make *one hundred grammes.* Dissolve the Iron Ammonium Citrate in *one hundred cubic centimeters* of Distilled Water, and the Strychnine, together with the Citric Acid, in *twenty cubic centimeters* of Distilled Water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60° C., to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*, 1890.

This salt should never be prescribed in solution. E. R. Squibb has shown that it gradually deposits strychnine. When ammonia water or ammonium citrate was added, the precipitate was redissolved, but later the precipitate reappears. There might be dangerous or alarming symptoms if this solution were dispensed without shaking, and the last dose containing an undue proportion of the strychnine were administered. (*Ephem.*, June, 1888, p. 1128.)

It was officially described as in "thin, transparent scales, varying in color from garnet-red to yellowish-brown, without odor, and having a bitter, slightly ferruginous taste; deliquescent in moist air. Readily and completely soluble in water, partially soluble in alcohol." *U. S. VIII.* For method of assay see *U. S. D.*, 20th edition, p. 1446.

This combination has no advantages over the two active substances it contains when given conjointly in an uncombined state, and has the great disadvantage that the dose of one principle cannot be varied independently of that of the other.

Dose, from three to five grains (0.20 to 0.32 Gm.), in pill.

Ferric Peptonate. *Iron Peptonate. Peptonized*

Iron. Ferri Peptonas. Ferrum Peptonatum. Peptonate de Fer, Fr. *Eisen Peptonat,* G.—To a solution of 2 parts of dried peptone in 200 parts of water add a mixture of 24 parts of solution of dialyzed iron (See p. 1484) and 200 parts of water, in a thin stream while stirring constantly. A solution of caustic soda (1.5 per cent.) is added until there is produced a very weak alkaline reaction. The precipitated iron peptonate is washed rapidly with water until no reaction with silver nitrate is shown. The precipitate is drained on a wet strainer and dissolved in 3 parts of 25 per cent. hydrochloric acid. The solution is evaporated on a water bath and spread on plates to dry at a temperature not exceeding 50° to 60° C. Iron peptonate, thus prepared, is in the form of shining brown scales, and contains about 17 per cent. of iron. It is slowly soluble in cold water, more quickly in hot water, and the solution is not clouded by boiling nor by the addition of alcohol. Iron peptonate, its solution, and a syrup prepared from it are used in preference to inorganic salts of iron because of the absence of injurious effects upon the teeth and mucous membrane and its deficiency in astringency. The *dose* is from three to ten grains (0.2–0.65 Gm.).

Liquor Ferri Peptonati.—Solution of iron peptonate is now included in the N. F. and while made by a process somewhat different from that given above yields an essentially similar product.

Ferric Succinate. *Ferri Succinas. Iron Succinate.*—The precipitate obtained by adding ferric chloride to a solution of a succinate is a basic salt $(C_4H_4O_4)_2Fe_2(OH)_2$. This is yellowish in color, becoming darker on standing. Ferric succinate has been introduced as a remedy for *jaundice* resulting from obstruction of the biliary duct; also as a chalybeate. *Dose,* five grains (0.32 Gm.).

Ferric Tannate. *Ferri Tannas.* $Fe_2(C_{14}H_7O_9)(OH_3)$.—This salt is prepared by dissolving 44 parts of precipitated ferric subcarbonate, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 80° C., in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, ferric tannate is in flat pieces, of a crimson color, without taste, and insoluble in water. It is not a definite chemical compound. *Ink* is an aqueous solution of the ferric gallotannate, and probably possesses similar medicinal properties. It is a popular application for *ringworm. Dose,* of ferric tannate, from eight to thirty grains (0.5–2.0 Gm.), in the course of the day.

Ferric Valerate. *Ferri Valerianas. U. S.* 1890. *Iron Valerianate.* $Fe_2(C_5H_9O_2)_2(OH)_4$.—This salt was at one time official in the U. S. Pharmacopœia, but was dismissed from the 8th revision. It may be prepared by precipitating a dilute solution of ferric sulphate with a solution of sodium valerate and collecting and washing the precipitate. When so made it forms a dark brick-red powder of somewhat varying composition with the characteristic odor of the valerates. It is insoluble in water, but readily soluble in alcohol. It is decomposed by boiling water with the liberation of valeric acid and the formation of ferric hydrate.

Ferric valerate has been used as a chalybeate, especially in *nervous exhaustion* associated with *anemia.* It has also been alleged to have almost specific properties in *diabetes insipidus.* The *dose* is from two to five grains (0.13 to 0.32 Gm.).

Ferrichthyol.—This compound occurs as an amorphous, dry powder of brownish-black color, devoid of taste and containing 3.5 per cent. of iron combined with ichthyol. It is employed as a hematinic in daily *doses* of thirty grains (2.0 Gm.).

Ferripyrine. *Ferropyrine. Antipyrina cum Ferro.*—This compound is prepared by adding 5 parts of crystallized ferric chloride, dissolved in 10 parts of 96 per cent. alcohol, to a solution of 5 parts of antipyrine in 10 parts of alcohol and 50 parts of ether. It is in the form of a fine, orange-red powder, containing about 64 parts of antipyrine, 24 parts of chlorine and 12 parts of iron. Soluble in 5 parts of water at 15° C., less soluble (9 parts) in boiling water, very soluble in alcohol but insoluble in ether. Alkalies or alkaline carbonates added to an aqueous solution precipitate ferric hydroxide. It combines the properties of both antipyrine and ferric chloride and is given in *anemic conditions* accompanied by *headache.* It has been used in *chlorosis* as a chalybeate; is strongly astringent, and affirmed to be often useful in chronic *diarrheas.* In strong solution (1 to 5) it is said to be a powerful non-irritant styptic. *Dose,* from three to six grains (0.2 to 0.4 Gm.).

Ferrivine.—Ferrivine is claimed to be ferric tri-para-amino-benzene sulphonate. It has been introduced by McDonagh as a cure for *syphilis* by intramuscular injection. Harrison and Mills (*L. L.,* June 17, 1916), however, from clinical trials, reached the conclusion that not only did the drug fail to show any curative action but that its use was distinctly dangerous because of the violence of the reactions following its injection. It was intended to be used with a sulphur compound called *Intramine.*

Ferromangan. *N. N. R.* 1924. *Liquor Ferro Mangani Peptonati,* "Dieterich."—This is a proprietary solution containing 0.6 per cent. of iron, 0.1 per cent. of manganese and 1.5 per cent. of peptone. It is a clear liquid of a dark brown color and a pleasant odor and taste. The N. F. *Liquor Ferri Peptonati et Mangani* is of similar composition. It is used in *anemia, chlorosis* and as a general tonic in a *dose* of from one to four fluidrachms (3.75 to 15 cc.).

Ferro-silicon.—This is a mixture made by heating quartz, steel turnings and coal in an electric furnace and is used in the arts for increasing the tensile strength of steel. Its interest to medicine depends upon the fact that in the presence of moisture it evolves hydrogen phosphide and also hydrogen arsenide and has caused several deaths upon ships in which it was being transported. As a result of an investigation under the direction of the British Government, it was recommended that *ferro-silicon* should be exposed to the air for at least a month before being sold, that its carriage on passenger vessels should be forbidden and that when carried on cargo boats it should, if possible, be carried on the deck, or at least in well-ventilated places, cut off by air-tight bulkheads from the quarters of the crew.

Ferrous Arsenate. *Ferri Arsenas. Br.* 1898. *Iron Arsenate. Arsenate of Iron, Br.* 1885. *Ferrum Arsenicum. Arséniate Ferreux,* Fr. Cod. *Arsensaures Eisenoxydul,* G. *Arseniato ferroso-ferrico,* It. *Arseniato de hierro,* Sp.—" Ferrous arsenate,

$Fe_3(AsO_4)_2,6H_2O$, with ferric arsenate and some iron oxide." *Br.*, 1898.

Ferrous arsenate is white when first formed, but quickly turns green on exposure to the air during the process of washing and drying, and finally becomes a *ferroso-ferric arsenate* of the probable composition $3Fe(FeO)AsO_4.16H_2O$. It is an amorphous powder, without odor or taste, insoluble in water, but readily dissolved by hydrochloric acid. The British Pharmacopœia gave the following characters of the salt: "A tasteless amorphous powder of a greenish color, insoluble in water, but readily dissolved by hydrochloric acid. It affords the reactions characteristic of ferrous and ferric salts and of arsenates." For further tests for this salt see *U. S. D.*, 20th edition, p. 1392.

Ferrous arsenate is supposed to unite the virtues of the two metals which enter into its composition, but the quantity of iron in any permissible dose is so small as to be nearly or quite insignificant, and the activity of the medicine is in fact due to the arsenic alone. The complaints in which it has been found efficient are those in which arsenic in other forms has proved to be a valuable remedy, and it ought undoubtedly to be so ranked rather than with the chalybeates. Should the coexistence of an anemic state of the system with any disease requiring the use of arsenic indicate the joint use of iron, it would be unsafe to depend on ferrous arsenate alone. This remedy is useful in chronic affections of the skin, especially those of a scaly character, as *lepra, psoriasis*, and the advanced stage of *eczema* and *impetigo*.

Dose, from one-tenth to one-eighth of a grain (0.006 to 0.008 Gm.).

Ferrous Bromide. *Iron Bromide. Ferri Bromidum. Ferrum Bromatum. Bromure ferreux, Bromure de fer*, Fr. *Eisenbromid*, $FeBr_2$.—*Ferrous bromide* is a yellowish, deliquescent salt, very soluble, and extremely styptic. For medicinal employment it should be in aqueous solution, protected by sugar. This solution has been used with alleged success as an alterative tonic in *chorea*, and in various *scrofulous* and *erysipelatous affections.* (See 16th ed., *U. S. D.*) The *dose* of ferrous bromide is from one to three grains (0.065–0.2 Gm.), three times a day, gradually increased until its effects are manifested.

Ferrous Iodide. *Ferri Iodidum. Iron Iodide. Iodure de Fer*, Fr. *Ferrum Jodatum. Eisenjodür, Jodeisen*, G. $FeI_2 + 3H_2O$.

The solid ferrous iodide in its unprotected state is omitted in the present editions of the U. S. and Br. Pharmacopœias. The former directs it in pills and syrup prepared immediately from the materials. The iodide is extremely liable to spontaneous change.

Ferrous iodide is a crystalline substance, exceedingly deliquescent, of a greenish-black color, and styptic, chalybeate taste. Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray color and metallic luster. At a higher temperature it emits violet colored vapors, and the iron is left in the state of sesquioxide. It is very soluble both in water and in alcohol. When recently prepared it is wholly soluble in water, forming a pale green solution; but, if made for some time, it almost unavoidably contains some ferric oxide, from a partial decomposition, and will not entirely dissolve. The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing ferric oxide. According to Richard Phillips, Jr., the first step in this change is the formation of ferrous oxide and hydriodic acid, from the decomposition of water. As the ferrous oxide immediately begins to be converted into ferric oxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free, and hence is explained the acidity of the solution from the first moment the ferric oxide is deposited. Afterwards, the hydriodic acid is decomposed by the air, and iodine liberated. (*P. J.*, iv, 19.) The plan of Squire of placing in it a coil of iron wire does not prevent the deposition of ferric oxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Syrupus Ferri Iodidi.*) Ferrous iodide is incompatible with alkalies and their carbonates, with lime water, and with all other substances by which ferrous sulphate is decomposed.

Ferrous iodide was first employed in medicine by Pierquin in 1824. For uses of this preparation, see *Syrupus Ferri Iodidi*, Part I. The *dose* is a grain (0.065 Gm.), gradually increased to eight grains (0.5 Gm.).

This salt, on account of its deliquescent property and proneness to decomposition, should not be given in pill, unless protected from change by saccharine matter by coating or other means. (See *Pilulæ Ferri Iodidi*, p. 864.) The most convenient form of exhibition is that of a syrup, but it has no advantage over the official syrup. For a process for making *Glycerite of Ferrous Iodide*, see *U. S. D.*, 19th ed., p. 1491. *Iron Iodates* have been used to some extent as therapeutic agents in Dublin. For formulas, see *P. J.*, i, 624.

Ferrous Malate. *Ferri Malas Crudus.*—Under the name of *extractum ferri pomatum* (*ferrated extract of apples*) the N. F. recognizes an impure form of ferrous malate made by digesting fresh apple juice with reduced iron and evaporating to the consistency of a pilular extract. It is of a dark green color and contains varying quantities of iron. *Dose*, five to fifteen grains.

Ferrous Oxalate. *Ferri Oxalas. U. S.* 1880. *Iron Oxalate.* $FeC_2O_4H_2O$. *Ferrum Oxalicum. Oxalas Ferrosus. Oxalate de Fer*, Fr. *Oxalsaures Eisenoxydul*, G.—For description of this salt which was recognized by the U. S. P. 1870 and 1880, see *U. S. D.*, 19th ed., p. 1491. It is a very feeble, inefficient chalybeate. *Dose*, from two to three grains (0.13–0.20 Gm.).

Filicon.—A tænicide consisting of an extract of the rhizome of *Aspidium spinulosum* (Mill.) Sw. (Fam. *Filices*) combined with an aromatized castor oil. The *dose* is stated to be one tablespoonful.

Flindersia. *Flindersia maculosa* (Lindl.) F. Muell. *Leopard Tree.*—This is a tree of New South Wales, belonging to the *Meliaceæ.* During the summer it yields large masses of a clear amber-colored gum, which has a pleasant taste and is eaten by the aborigines; it has been used as a remedy for *diarrhea.* *Leopard tree gum* occurs in pieces as large as pigeons' eggs, dissolves rapidly in cold water, and has been found by J. H. Maiden to contain 80 per cent. of arabin but no metarabin. (*P. J.*, vol. xxi, 1890.)

Flour. *Farina tritici. Wheat flour.*—According to the official standards of the U. S. Department of Agriculture (see Circular 19, Bureau of

Chemistry), "Flour is the clean, sound product made by bolting wheat meal and contains not more than 13.5 per cent. of moisture, not less than 1.25 per cent. of nitrogen, not more than 1 per cent. of ash, and not more than 0.5 per cent. of fiber." The same circular states that "Graham flour is unbolted wheat meal" and "Gluten flour is the clean, sound product made from flour by the removal of starch and contains not less than 5.6 per cent. of nitrogen and not more than 10 per cent. of moisture."

The farina or flour produced by grinding other grains is designated by the appropriate prefix in each case, as maize or corn meal, rice flour, oatmeal, rye flour, buckwheat flour, etc.

The highest grade of wheat flour is known as "patent"; other grades are known as "bakers' flour" or "low grade flour." A barrel of flour weighs 196 pounds and requires about 258 pounds of wheat for its manufacture.

There are many trade designations for grades of flour, such as, "family," "blended," "gluten," etc., some of which (especially the last) are frequently misleading, if not actually illegal.

The nutritive value of flour depends upon a number of factors and the average composition of good flour is as follows: Moisture, 12.5 per cent.; proteids (N. x 5.70), 9.6 per cent.; dry gluten (including proteids), 10 per cent.; fat, 1.0 per cent.; ash, 0.5 per cent.; starch, 75 per cent.; crude fiber, 0.2 per cent.

The character of a wheat flour is measured largely by the quantity of gluten which it may contain. The separation of the gluten is accomplished by making a sticky, doughy mass with the flour by adding a small quantity of water, after which it may be washed with water accompanied with constant kneading until the gluten alone remains, which can be determined by the washings being no longer milky in appearance. The excess of moisture may then be removed from the gluten by squeezing and rolling it, after which it may be weighed as moist gluten (varying in amount from 25 to 35 per cent.), or dried to constant weight at 100° C. and calculated as dry gluten (which runs from 9 per cent. to 12 per cent. in ordinary flours).

The modern demand for a pure white flour has led to processes of grinding wheat which lead to the complete rejection of the outside layers of the grain. This highly-milled flour is deficient in phosphates and other mineral salts but especially in vitamin content. Although on a mixed diet this is not a matter of great importance, Little (*J. A. M. A.*, 1912, lviii, 2029) has reported an outbreak of beri-beri among the fishermen of Newfoundland who live mainly on white bread.

As flour is usually valued in proportion to its whiteness it has been extensively bleached in the past by the use of ozone or of oxides of nitrogen or by nitrosyl chloride. The question of the effect of bleaching upon the digestibility or harmlessness of bleached flour has never been satisfactorily settled. It is a practice which is very prevalent at present because of the foregoing fact and the unwillingness of the authorities to antagonize the milling trade.

Adulteration of flour, which was formerly very common, has not been practised to any extent for years in the United States. Occasionally samples are seen in which foreign seeds, smut, etc., have been ground with the grain, owing to insufficient cleaning of the grain preparatory to grinding. Such gross adulterants as terra alba or soapstone, which were formerly reported are unheard of at the present time and even the practice of the addition of copper sulphate or alum in small proportions to flour, which was formerly made by bakers who were thus enabled to bake white bread from inferior grades of flour, seems to have been altogether abandoned. (For methods of testing flour see any modern work on food analysis.)

The proteids of wheat, usually included in the term "gluten," are several in number and, according to Osborne and Vorhees (*Am. Chem. J.*, xv, 392; xvi, 524) are as follows: Globulin, 0.6 to 0.7 per cent.; albumen, 0.3 to 0.4 per cent.; proteose, 0.3 per cent.; *gliadin*, 4.25 per cent.; *glutenin*, 4 to 4.5 per cent.

The last two are the only ones present in gluten as determined by the washing out process previously described, as the first three are soluble in water.

"*Gluten*" is a term popularly known in connection with the names "gluten flour" and "gluten bread," used and recommended especially in connection with the dietary of diabetics when starchy foods are to be administered in small amounts or altogether prohibited. These preparations are legion and in many instances are sold under claims which are as false and misleading as they are cruel in the hope which they hold out to the sufferer from the disease. For a complete discussion of these products with analyses of hundreds of commercial samples, see *Bull. Conn. Ag. Exp. Sta.*, 1913, on Diabetic Foods.

Pure Gluten prepared by the mechanical method described above for its estimation is sometimes used in combination with medicating agents, some of which, like certain salts of the metals, form insoluble and tasteless compounds with it.

It is scarcely necessary to state that *bread* is formed by making flour into a paste with water, with the addition of yeast, setting it aside to ferment, and then exposing it to the heat of an oven. The fermentation excited by the yeast is accompanied by the extrication of carbon dioxide, which, being retained by the tenacity of the gluten, forms innumerable little cells or bubbles throughout the mass, and thus renders the bread light.

Wheaten flour is no longer used in its unaltered state in medicine. It was at one time employed as a desiccant dusting powder but has been completely replaced by powdered starch. A poultice is often made by boiling bread with milk. The effects of this poultice are similar to those of a flaxseed poultice although it does not hold the heat so well. The crumb (*mica panis*) is, moreover, frequently used to give bulk to minute doses of very active medicines administered in the form of pill. It should be recollected that it always contains common salt, which is incompatible with various substances.

Bran is laxative, and may be used with advantage to prevent *costiveness*. Bran bread, made from the unsifted flour, is an excellent laxative article of diet in some dyspeptic cases. The action of the bran is probably mechanical, consisting in the irritation produced upon the mucous membrane of the bowels by its coarse particles.

Flumerin. *Di-sodium-hydroxy-mercuric-fluorescein.*—This is a dark red powder with a greenish iridescence, slightly hygroscopic but otherwise permanent in the air. It is soluble in about ten parts of water, the solutions generally being permanent, although on long standing they sometimes show a slight precipitate of metallic mercury. The salt represents 32.5 per cent. of mercury so combined that it is not precipitated by either hydroxids or blood serum.

Flumerin has been brought forward by Hill and Young (*J. A. M. A.*, 1923, lxxx, p. 1365) for the treatment of *syphilis.* They gave it intravenously in doses of 0.5 milligramme per kilo of body weight; this for a man of 150 pounds would be equivalent to about one-half of a grain (0.03 Gm.) every other day.

Fluorescein. *N. N. R.* 1924. *Fluoresceinum. Resorcinolphthalein. Dioxyfluoran.* $O:(C_6H_3OH)_2:C.C_6H_4.COO$.—This may be prepared by heating phthalic anhydride (5 parts) with resorcinol (7 parts) to 200° C. The mass is treated with water and the residue dissolved in solution of potassium hydroxide, after filtration the *fluorescein* is precipitated by an acid. It is a yellowish-red or dark red powder, soluble in alcohol with yellow-red color and green fluorescence. The sodium salt, *uranin* (*sodio-fluorescein*), $C_{20}H_{10}O_5Na_2$, and the potassium salt (*potassio-fluorescein*) are marketed. They differ in that the first is a brownish-yellow and the second a yellowish-red powder; both of them yield aqueous solutions which are red by transmitted light and exhibit an intense yellow-green fluorescence.

An aqueous solution containing ten grains (0.65 Gm.) of fluorescein with fifteen grains (1 Gm.) of sodium bicarbonate to the ounce (30 cc.) is used as a diagnostic agent in various ophthalmic conditions. In lesions of the cornea two per cent. solution is dropped into the eye, and those portions which are deprived of the epithelium will show a green discoloration, while the healthy parts of the cornea remain unaffected. The eye should be cocainized before applying the fluorescein. According to Hamberger (*All. M. C. Z.*, 1909, p. 368), if thirty to forty-five grains (2–3 Gm.) be given by the mouth, while the body becomes yellow as in jaundice, in the healthy eye there is no change of color. When there is intra-ocular disease, however, the aqueous humor assumes a bright green color. In diseases of the conjunctiva, the eye reacts as though healthy.

Fluorescein sodium has been recommended by Strauss (*B. K. W.*, 1913, p. 2226) as a test for renal function. He administers fourteen grains (1.0 Gm.) on an empty stomach. In healthy individuals the urine shows fluorescence within ten to twenty minutes and continues for thirty-five to forty hours; the continuation of the dye in the urine for a longer time is indicative of kidney disease.

It is also used as a test for death. It is stated that if 15 grains be injected into the human body the whites of the eyes will become a greenish color provided life remains, within one hour. After death there is no coloration. It is also used for the purpose of tracing the course of underground streams and the connection between cess-pools and wells. One part in two billion can be recognized in water.

Fluorescein-Zinc is a reddish-yellow, difficultly soluble powder of the composition $ZnC_{20}H_{10}O_5$. Its zinc content is 16.4 per cent. It has been used by Wolff (*Ph. Ztg.*, 1915, 181) with asserted benefit as an antiseptic in *conjunctivitis.*

Owing to the close similarity in name between fluorescein and its derivative *fluorescin* much confusion has arisen, leading to the general belief that the two substances are identical. Fluorescin, however, is a reduction product of fluorescein, made by acting on the latter with sodium hydrate and zinc dust. It occurs as a yellow powder readily oxidizable to fluorescein. It is used like fluorescein as a diagnostic agent in ophthalmic practice. It has also been recommended by Fleig (*Press. Med. d'Egypte*, 1910, p. 281) as a test for the presence of blood in the urine. The test depends upon the fact that the non-fluorescent fluorescin-sodium shows an intense fluorescence in the presence of blood when treated with hydrogen peroxide.

Fluorides.—*Hydrofluoric acid* is a pungent, fuming, acid gas, very corrosive, attacking glass and porcelain and etching its surface. It is very soluble in water, the specific gravity of the solution rising to 1.25. The concentrated aqueous acid becomes weaker on boiling until, when boiling at 120° C., it attains a constant composition of from 36 to 38 per cent. of the anhydrous acid. Anhydrous hydrofluoric acid has been prepared and concentrations of all degrees may be obtained by the dilution of this acid. The concentrated acids are kept in containers of lead or platinum while more dilute acids are kept in gutta percha or ceresin bottles.

A 60 per cent. acid is employed in the cut glass industry for polishing lead, potash, soda and lime glass. Spent hydrofluoric acid, after use in the industry, is made use of by adding an equal volume of the 60 per cent. acid and about 10 per cent. of strong sulphuric acid. Stamping or etching upon glass for the purpose of putting trade marks, etc., upon glassware is accomplished by means of a rubber stamp using, in place of ink, a paste made of 2 parts of 50 per cent. hydrofluoric acid and 1 part of ammonium carbonate with enough barium sulphate to form a thick paste which may then be spread on a pad. Concentrated hydrofluoric acid is a powerful corrosive, having the peculiar property of hardening the skin or tissue with which it comes in contact and continuing its action underneath the hardened tissue, with an extraordinary amount and persistency of pain. For case, see *B. M. S. J.*, Jan., 1882; also *B. M. J.*, 1880, i. According to L. A. Waddell (*Indian Med. Gaz.*, 1883), the dilute 8 per cent. acid applied to the skin causes stinging sensation and pallor, followed by redness and desquamation. From 15 to 20 per cent. acid destroys the epithelium and produces severe burning and aching pain. The vapor of the acid is exceedingly irritant to the lungs, causing, even when very dilute, spasm of the glottis and other symptoms of irritation. According to Husemann, death has been produced by it. Nevertheless, L. Olivieri and F. Mergoni affirmed that in solution of 33 per cent. the daily inhalation of hydrofluoric acid from half an hour to an hour is a valuable adjuvant to quinine in chronic *malaria.*

Alkaline Fluorides.—According to the studies of Tappeiner (*A. E. P. P.*, xxvii), the fluorides are powerfully depressant to the blood pressure through an action upon the vasomotor centers and also produce lowering of the bodily temperature. Death occurs, amid symptoms of collapse, from respiratory failure. Waddell found in his studies a marked decrease in the number of red blood cells which he believed, but does not prove, to be the result of a direct action upon the spleen. Schwyzer (*Biochem. Zeit.*, 1914, lx, p. 932) finds that the continued intake of sodium fluoride in doses of 1 to 2 milligrammes per kilo causes increased coagulability of the blood and irritation of the bone marrow with a loss of chlorine and calcium. He believes that these symptoms are due to the affinity of hydrofluoric acid for calcium with which it forms insoluble salts.

Sodium fluoride has been used by various authors in the treatment of *goiter*, *rheumatism*, *epilepsy*, and *phthisis*. Its value, however, is extremely questionable and it is certainly toxic. McNally (*J. A. M. A.*, 1923, lxxxi, 811) reports 4 cases of fatal poisoning by sodium fluoride with extensive references to the literature. The fatal dose for a man is between 5 and 10 Gm. (75 to 150 grains). The most common symptoms are epigastric pain, nausea, vomiting, diarrhea with frequently local paralysis either in the legs or face. Necropsy shows congested and edematous mucous membrane of the stomach and upper bowel with often scattered hemorrhages. Most of the cases resulted from the mistake of roach powder for baking powder. The *dose* which has been recommended is from one-sixth to one grain (0.01–0.065 Gm.).

The fluorides are active antibacterials. (*M. R.*, 1908.)

Ammonium Fluoride.—Under the name of *bifluoride of ammonium* a solution containing 20 per cent. of hydrogen-ammonium fluoride, and 10 per cent. of hydrofluoric acid has been used by Dr. Joseph Head in the treatment of *pyorrhea alveolaris*. This solution is actively germicidal, having a phenol coefficient of 5.82. According to Head it is not caustic to wet mucous membranes, although on dry it produces a burn like that of carbolic acid. It is applied by flowing it into the pus pockets; it should never be injected into the tissues and care should be taken to prevent it coming in contact with the mucous membranes in other parts of the mouth. Dr. Head claims for this solution that it aids in loosening the tartar as well as in destroying infective micro-organisms and that it is not injurious to the tooth.

A technical form of ammonium fluoride is used in cleaning granite and stonework and sometimes as an ingredient in roach poisons.

Silver Fluoride. AgF. *Tachiol.*—This salt, which occurs in deliquescent crystals acquiring a yellow color in the air and finally being converted into a black crystalline mass, making stable solutions in water, has been brought forward by Durante and Perez as a valuable antiseptic for surgical use. It is a feeble coagulant of albumin, and great penetrating power is claimed for its solution. It is employed in the proportion of one to a thousand; the one per cent. solution is said not to be distinctly irritant to the skin. It blackens linen and other organic substances. Zappuli has destroyed *malignant pustules* by injecting into them silver fluoride solution.

Organic Fluorides.—A number of organic fluoric compounds have been proposed and put upon the market. According to Tischer and Beddies (*Aerzt. Rund.*, 1898), they are antispasmodic, bactericidal, and are primarily stimulant, secondarily depressant to the motor nerve.

Difluor-diphenyl is described elsewhere under its trade name, *Antitussin.*

Formalbumin.—A condensation product of formaldehyde and casein is a yellowish, odorless powder, soluble in diluted acids. It is used as an external antiseptic. A similar combination is sold under the name of *galalith* and is used as a plastic for making toilet articles, etc., similar in appearance to celluloid.

Forman. *Chlormethylmenthyl-ether*, $C_{10}H_{19}$—$O.CH_2Cl$, a product formed by the action of formaldehyde upon menthol in the presence of hydrochloric acid. It is a colorless oil, emitting dense fumes and boiling at 160° to 162° C. under a pressure of 16 mm. In the presence of water or merely moist air the ether splits up into its original constituents, formaldehyde, menthol, and hydrochloric acid. It has been used locally in the treatment of various conditions of the nasal and even bronchial mucous membrane.

Formasal.—Under this name has been introduced a condensation product of formaldehyde and salicylic acid which is claimed to be a *methylene disalicylic acid.* Several salts of this acid are upon the market, including those of caffeine (*cafformasal*), bismuth (*bisformasal*) and sodium (*sodiformasal*).

It is claimed for *formasal* that it is decomposed in the system, liberating both salicylic acid and formaldehyde. Its sodium salt is used as an anti-rheumatic and anti-neuralgic in doses of five to fifteen grains (0.32–1.0 Gm.). The bismuth salt is used as an intestinal antiseptic. The dose is ten to twenty grains (0.65–1.3 Gm.). The caffeine salt is very soluble in water, and has been suggested as a means for the hypodermic administration of caffeine. It is used as a diuretic and in *rheumatism* in *doses* of five to fifteen grains (0.32–1.0 Gm.).

Formicin. (*Formaldehyde Acetamid.*) $CH_3.CO.NH.CH_2.OH$.—This product is prepared by a patented process involving the action of a formalin polymer on acetamid.

Because of its hygroscopic qualities, *formicin* is marketed only in concentrated solution. It is a colorless, syrupy liquid, specific gravity, 1.25, of a characteristic odor, miscible in all proportions of water, alcohol or chloroform. The addition of either acids or alkalies causes the liberation of formaldehyde. With Mayer's reagent it gives a reddish-violet color. According to Koch (*Ph. Ztg.*, 1905) this agent exercises at body temperatures a powerful bactericidal effect probably due to the liberation of formaldehyde. It has been used in strengths of from 2 to 5 per cent. for disinfecting internal cavities, as the bladder, and also as an injection in suppurative infection of the joints. Bartholdy (*D. M. W.*, 1906, p. 1601) has injected as high as 2 cc. of the 5 per cent. solution daily into a child of eight years without causing any systemic symptoms. According to this author it has the great advantage over formaldehyde of causing practically no pain.

Fortoin.—This is obtained by the action of formaldehyde upon *cotoin*, the active principle of the true coto-bark. Its composition is

$$CH_2\left\langle\begin{matrix}C_{14}H_{11}O_4\\C_{14}H_{11}O_4\end{matrix}\right.$$

and it is therefore to be viewed in the light of a *methylenedicotoin.* ***Fortoin*** forms yellow needles or a yellow powder emitting a feeble cinnamon-like odor; it is freely soluble in chloroform, acetone, glacial acetic acid, and dilute alkalies, but dissolves sparingly in alcohol and ether, while in water it absolutely insoluble; melting point, 211° to 213° C. It is claimed for *fortoin* that it has the peculiar action of cotoin upon the intestinal mucous membrane, united with the antiseptic and disinfecting properties of formaldehyde. It is used in those cases of *chronic intestinal catarrh* in which there is no active inflammatory process. It has been also recommended by Overlach as a local application in badly *ulcerated sore throats* and in *gonorrhea.* In making local applications from one to six grains may be dissolved in a fluidounce of ten per cent. alcohol. *Dose,* four to seven grains (0.26–0.45 Gm.) three to five times a day.

Frankenia. *Frankenia grandifolia* Cham. and Schlecht. *Yerba Reuma.* (Fam. *Frankeniaceæ.*)—This herb, which grows in California, Nevada, Arizona and Northern Mexico, contains about 6 per cent. of tannin and is employed as a topical remedy in *catarrhal affections,* especially of the nose and genito-urinary tract; also internally in *doses* of from ten to twenty minims (0.6–1.3 cc.) of the fluidextract. For local application the fluidextract may be diluted with from two to five times its volume of water.

Frasera. *American Columbo. Radix Fraseræ. Radix Columbo Americanæ. Racine de Colombo de Mariette (d'Amérique),* Fr. *Frazerawurzel, Amerikanische Colombowurzel,* G.—*American Colombo* is yielded by *Frasera caroliniensis* Walt. (Fam. *Gentianaceæ*), a smooth biennial or triennial herb which flourishes in rich dry soil from New York and Wisconsin southward. The plant attains a height of up to 2.5 m. Its roots are thick and fleshy; its leaves are oblong-lanceolate and arranged 4 at each node; its pale greenish-yellow and brown-purple dotted flowers are borne in a loosely flowered, pyramidal panicle, appearing from May to late June. The roots, which were formerly included in the Secondary List U. S. P., should be collected in the autumn of the second or the spring of the third year. Before being dried, they should be cut into transverse slices.

As formerly in the market, Frasera was in disc-like pieces resembling calumba, but are easily distinguishable by the greater uniformity of their internal structure, the absence of concentric and radiating lines, and their purer yellow color, without a greenish tinge. The root sliced longitudinally, so as to imitate gentian, has been offered in the market as *American gentian.* The taste of frasera is bitterish and sweetish. It contains gum, pectin, glucose, wax, resin, fatty matter, yellow coloring matter, bitter extractive, and an acid which is probably peculiar. (*A. J. P.,* Jan., 1862, 23.)

Frasera is a feeble, simple bitter. *Dose,* of powder, one drachm (3.9 Gm.); of infusion (1 fl. oz. to 1 pint boiling water), two fluidounces (60 cc.) a day. The fresh root is said to be emetic and cathartic.

Fruit Essences, Artificial.—Several of the esters of alkyl radicals with organic acids have been found to possess the odor and flavor of certain fruits, a property which has led to their employment as flavoring materials under the name of fruit essences. They are esters, which, according to the older nomenclature, were improperly called "ethers" or "compound ethers."

Ethyl Butyrate. Ethyl-butyric Ester. $C_3H_7COOC_2H_5$.—Butyric ether, as it is sometimes erroneously called, is sparingly soluble in water, but very soluble in alcohol, and boils at 121° C. It is used to communicate a pineapple flavor. Dissolved in 8 to 10 parts of alcohol, it formerly was sold under the name of *pineapple essence. Butyric acid,* $C_4H_8O_2$, is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and which is preceded by the lactic fermentation. Butyric acid is a colorless liquid, of disagreeable odor and taste resembling rancid butter. It dissolves in all proportions in water and alcohol, boils at 163° C.; density, 0.973.

Ethyl Pelargonate. Ethyl-pelargonic Ester. Œnanthic Ether. $C_8H_{17}COOC_2H_5$.—This compound has the agreeable odor of quince, and when dissolved in alcohol in due proportion, was formerly sold as *quince essence.* It may be obtained from wine lees, by adding sulphuric acid and water, and distilling in a current of steam. Pure pelargonic ethyl ester (œnanthic ether) is a colorless liquid, having a peculiar, vinous, stupefying odor, and a taste at first slight but afterwards acrid. Its sp. gr. is 0.8635 at 17.5° C. and its boiling point from 227° to 228° C. It is insoluble in water, but dissolves readily in alcohol and ether. It has been much used in the production of factitious or imitation brandy. *Pelargonic acid,* first obtained from *Pelargonium capitatum* (L.) Ait., or *rose geranium,* belongs to the fatty acid series and has the formula $C_8H_{17}COOH$. Delff's analysis of *œnanthic acid* gives it the same composition, and he considers the two acids identical. This ester is one of those naturally found in grape brandy and the artificial ester is much used in preparing artificial brandies.

Amyl Acetate. Amyl-acetic Ester. Pentyl Acetate. $CH_3COOC_5H_{11}$.—It is a colorless, limpid liquid, lighter than water, boiling at 137° C., insoluble in water, but soluble in alcohol. It is manufactured on a large scale as a solvent for lacquers and varnishes under the name of *banana oil* on account of the resemblance of the odor of the ester to that of ripe bananas. An alcoholic solution of this ether also has been sold under the name of *Jargonelle pear essence.* This ester is commercially sold under the name of "banana oil," and is the solvent used largely in lacquering, the film, as a rule, consisting of pyroxylin which is quite soluble in amyl acetate.

Amyl Valerate. $C_4H_9COOC_5H_{11}$. *Amyl Valerianate. Amyl-valeric Ester. Apple Oil.*—It boils at 188° C., and has a sp. gr. of 0.879 at 0° C. An alcoholic solution of this ester, in the proportion of one part to six or eight of alcohol, has been used as a flavoring liquid under the name of *apple essence.* (See *Valeric Acid.*)

Besides the essence here described, there are found in commerce the strawberry, raspberry, apricot, greengage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the esters of the ethyl and amyl series, modified by the addition of pure nitrous ether, tincture of orris, vanilla, volatile oils, etc., to bring about a resemblance to the fruit the odor and taste of which it is the object to imitate.

The fruit essences have been extensively employed in the past for flavoring ices, jellies, lozenges, and drops and for making fruit syrups and effervescent beverages. They are, however, vastly inferior to the concentrated juices and extracts from the real fruits, and their use is largely being abandoned on account of the necessity of labeling the products thus made as artificial or imitation under existing federal and state food laws.

Kletzinsky prepared a table giving the ingredients, and their proportions, of a large number of fruit essences. (See *U. S. D.,* 19th ed., p. 1497; also a paper by George R. Pancoast and Willard Graham, *Proc. Penn. Phar. Assoc.,* June, 1906.)

Fuchsine. *Magenta Red, Aniline Red, Azaleine, Solferino, Harmaline, Erythrol-benzin, Rosein,* *Rubin.*—This compound is now included among the U. S. P. reagents (see Part III). It is a mixture of salts of *rosaniline* and *pararosaniline.* One of the earliest coal-tar colors discovered, it has had an extended use for many years. The poisonous results which have been alleged to follow the use of fuchsine as a coloring for foods and as a dyestuff for fabrics, have been undoubtedly due to arsenical impurities remaining in the dye from its manufacture. There is still some doubt, however, as to its properties in this respect, and it is not included in the seven permitted colors under the ruling of the U. S. Dept. of Agriculture.

Fuchsine and *safranine,* $C_{21}H_{20}N_4$, were formerly largely employed in France for coloring wines red. In the experiments of Cazeneuve and Lépine (*G. H. M. C.*, Nov., 1885) fuchsine was found to be free from toxic properties, but safranine proved itself a violent poison, causing marked dyspnea, acceleration of the heart's beat, violent diarrhea and albuminuria, and death from respiratory paralysis. It stains animal tissue directly violet-red while vegetable fiber must first be mordanted.

Reiss (*G. H. M. C.*, 1888) recommends fuchsine as a specific in *acute* and *chronic Bright's disease.* Fuchsine, according to Weber and Krause (*B. K. W.*, 1907, p. 192) surpasses trypan red in its destructive action upon trypanosomes. It does not appear, however, to have been as yet tried in human trypanomiasis. According to May (*J. A. M. A.*, 1912, lviii, and 1913, lx) it is a powerful germicide rivalling phenol in its efficiency, and like many of the other dyestuffs stimulates granulation and epitheliazation. A number of other authors have reported favorable results in *varicose ulcers, burns,* and granulating *wounds* of various kinds. Triboulet also reports pleasing results in various *skin diseases,* especially *impetigo.* These conclusions have been confirmed by Gismondi (*Pediatria,* 1917, xxv, 718). It is used generally in strengths of about 1 per cent. either as an ointment or as an aqueous solution. *Dose,* of rosaniline, one-tenth to one-sixth grain (0.006–0.010 Gm.).

Fumaria. *Fumaria officinalis* L. *Fumitory. Beggary. Fumeterre,* Fr. *Erdrauch, Feldraute,* G. (Fam. *Fumariaceæ.*)—A small annual European plant, naturalized in this country, growing in waste places, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are dissected, compound, inodorous, have a bitter, saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. *Fumaric acid,* $C_4H_4O_4$, was early identified as present, and its isomerism with *maleic acid,* the acid obtained from malic acid by heat, was established later. The alkaloid *fumarine* first discovered by Peschier was at one time believed to be identical with corydaline, but according to Dankwortt (*A. Pharm.*, ccl, p. 590) is protopine. (See also Adermann, *A. J. P.*, 1890, 396.) Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. It has been used in *scurvy* and various hepatic disorders. Cullen gave two fluidounces (60 cc.) of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves, either fresh or dried, may be used in decoction or extract, in almost indefinite dose. The inspissated juice has also been employed.

Furfural. *a-Furol. Pyromucicaldehyde. Furfuraldehyde,* improperly called *furfurol. Artificial Oil of Ants.* $C_4H_3(CHO)O$.—A decomposition product of certain proteids, occurs in beer and brandy and is produced in the distillation of bran, pentoses, etc., with diluted sulphuric acid. It is a limpid, colorless liquid, soluble in 11 parts of water and freely in alcohol and ether.

A number of years ago Lauter Brunton suggested that the toxic effects of certain raw spirits might be due to action of furfural. McGuigan (*J. P. Ex. T.*, 1923, xxi, p. 65) finds that in doses of about 0.6 cc. per kilo by the mouth it produces marked symptoms and occasionally death in the lower animals; that it is a primary stimulant and secondary paralyzant of the central nervous system; that it causes formation of methemoglobin. He also finds that it possesses some local anesthetic and germicidal actions. The *dose* of one and a half grains (0.096 Gm.) of furfural produces in man a persistent headache. Ammonia is said to be antidotal to furfural, hence its value in "pick-me-ups." Furfural occurs as a by-product in the inversion of sugar by acids, and its presence in commercial invert sugar makes it possible to detect that substance when used to adulterate honey. (See test for invert sugar under honey.)

Fustic.—A yellow dye-wood, obtained from *Chlorophora tinctoria* (L.) Gaud. (*Maclura tinctoria* D. Don.), a tree of the Fam. *Moraceæ,* growing in the West Indies and South America. It is not used in medicine or pharmacy. The wood of *C. tinctoria* owes its coloring properties to two principles, which have been isolated by R. Wagner; one denominated *morin,* or *morindon,* $C_{15}H_{10}O_5$, and the other *moritannic acid,* $C_{13}H_8O_6$, from its resemblance to tannin. The former, when distilled with zinc dust, yields methyl-anthracene, whence the conclusion has been drawn that it is a *trioxymethylanthraquinone,* $C_{15}H_7O_2(OH)_3$. (See *Chem. Gaz.*, ix, 1, 21, and 241.) It has long been known in the Southwest that the wood of the *Osage orange tree, Maclura pomifera* (Raf.) Schneider, contains a dyestuff that would give a more or less fast yellow color. An examination of the wood from Texas by Kressmann showed that it not only contains *moric acid* and *morintannic acid,* the same as fustic wood, but also that the dyeing principles are present in amount to be commercially valuable. A comparative series of dyeing experiments made with fustic and Osage orange wood and extracts showed the latter to be of equal value with fustic in regard to depth of colors produced, the amount of extract, the character of the dyeing, and fastness to light, weather, washing, etc. (*Science,* 1914, 37.) Under the names of *Hungarian Fustic* or *Young Fustic* the wood of the *Rhus cotinus* L. (Fam. *Anacardiaceæ*), or *Venice Sumach* has also been used as a yellow dye. From it Chevreul extracted a yellow coloring matter, in small crystalline needles when pure, which he called *fisetin.* J. Schmidt (*B. Chem. G.*, xix) states that it occurs in the wood as a tannic acid compound of the glucoside of fisetin, which he calls *fustin.* The *fisetin* has the formula $C_{15}H_{10}O_6$, and is probably a *tetroxymethylanthraquinone,* $C_{15}H_6O_2(OH)_4$. It is obtained by recrystallization from dilute alcohol or acetic acid; it forms fine yellow needles or yellow prisms. It is very slightly soluble in hot water, easily soluble in alcohol and acetic ether, sparingly in ether and benzene.

Galactose. $C_6H_{12}O_6$.—*Dextro-galactose* has been used by Bower as a test for functional activity of the liver. (*W. M. W.*, 1906.) He found that in healthy persons after the administration of six hundred and twenty grains (40 Gm.) of *galactose* none appeared in the urine, but that in cases of cirrhosis of the liver after the same quantity the presence of galactose could be recognized in the urine.

Galbanum. *Gummi-resina Galbanum. Galban, Mutterharz,* G. *Galbano,* It., Sp.—This gum-resin was formerly official in both the U. S. and British Pharmacopœias. It is mentioned by the earliest medical writers and was an ingredient of the incense used in the worship of the ancient Israelites. At present it is only used to a small extent in medicine. Some confusion exists as to the botanical source of *Galbanum.* Buhse, during his travels in 1848, saw the gum-resin spontaneously exuding from a plant growing near the southern coast of the Caspian. He was informed by the natives that the drug was obtained from it. This plant is the *Ferula galbaniflua* Bassier and Buhse. Buhse also stated that the Persian galbanum is yielded by a second plant, the *F. rubricaulis* Boissier but Schumann considers this identical with *F. galbaniflua.* Holmes is of the opinion (*P. J.*, 1891, 194) that "Levant" galbanum is yielded by *Ferula galbaniflua*, and its variety *β-Ancheri;* that solid "Persian" comes possibly from *F. Schair* Borsez, while the *liquid* "Persian," judging from the fruits found in it, derived from an undescribed species allied to *F. galbaniflua.* All of the *Ferula* species mentioned are tall, umbelliferous herbs indigenous to Persia. These contain in their axes many schizogenous secretion reservoirs that secrete a milky fluid, the gum-resin. A portion of the drug is obtained by collecting the natural exudation from the stem, but most by cutting the stem off near the crown of the root and collecting the exuded juice after it hardens. Slices of the crown are taken off at intervals of several days as long as exudation continues. There are two commercial varieties of the drug, Persian and Levant. The Persian variety is soft, contains fragments of stems and fruits and at present is not on the American market. The Levant variety is in dry tears or lumps and contains transverse slices of roots. This variety has alone appeared on the American market within recent years. Most of the drug is exported from Persian Gulf ports.

Galbanum rarely appears in the form of masses composed of whitish, reddish, or yellowish tears, from the size of a pin's head to that of a pea and larger, irregularly agglutinated by a darker colored yellowish-brown or greenish substance, more or less translucent, and generally mixed with pieces of stems, seeds, or other foreign matters. (Persian Galbanum). It is usually found, in our markets, in the state of distinct roundish tears, about as large as a pea, or in lumps a yellowish-white, an orange brown or brownish-yellow color, shining externally as if varnished, translucent, and often adhering together. Internally the tears are soft, opaque and yellowish-white. Occasionally the tears are bluish-green in color. Galbanum has in cool weather the consistence of firm wax, but softens in summer, and by the heat of the hand is rendered ductile and adhesive. At 100° C. it is sufficiently liquid to admit of straining, and it generally requires to be strained before it can be used. It is of a dark-brown or blackish color, and of a soft consistence.

According to Ludewig, a gum-resin, designated as *Persian galbanum,* had been received in Russia by the way of Astrakhan or Orenburg, and is the kind used in that country. It came enclosed in skins, and was in masses of a reddish-brown color with whitish streaks, of a disagreeable odor, somewhat like that of asafetida, and of an unpleasant bitter, resinous taste. It was so soft as to melt with a slight elevation of temperature. It differed from common galbanum in its odor, in its color, which is never greenish, and in the absence of tears, and is probably derived from a different plant. It abounds in impurities. This variety of galbanum is probably the same as that obtained by Aitchison in Afghanistan, which on chemical examination yielded—volatile oil, 3.108 per cent.; resin (ether extractive, 61.2, alcohol extractive, 7.576), 68.776; water extractive (gum), 17.028; insoluble matter, 1056. (*P. J.*, Dec. 11, 1886.)

The odor of galbanum is characteristically aromatic; its taste bitterish, warm and acrid; its sp. gr. 1.212. Triturated with water, it forms an imperfect milky solution, which on standing deposits the greater portion of what was taken up. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the odor and taste of galbanum, and becomes milky with water, but affords no precipitate. In diluted alcohol it is wholly soluble, with the exception of impurities. Ether dissolves the greater portion. "When moistened with alcohol, galbanum acquires a purple color on the addition of a little hydrochloric acid." *U. S.*, 1880. According to Conrady (*A. Pharm.*, 1894, ccxxxii, 98) the composition of galbanum is as follows: ethereal oil, 9.5 per cent.; resin, soluble in alcohol, 63.5 per cent.; gum and impurities, 27 per cent. The purified resin was found by Conrady to contain about 20 per cent. of combined umbelliferone, about 0.25 per cent. of free umbelliferone, and about 50 per cent. of *galbaresinotannol.* This latter representative of the class of resino-tannols, first established by Tschirch, was proved to have the alcohol character by forming the acetyl and benzoyl derivatives. Conrady also considers that the umbelliferone is combined with this galbaresino-tannol in the form of an ester. The volatile oil which is obtained from galbanum to the extent of about 10 per cent. he found to consist essentially of a d-pinene hydrocarbon of the formula $C_{10}H_{16}$, with small amounts of a sesquiterpene, which, according to Wallach, is *cadinene* (Gildemeister and Hoffman, *Aetherische Oele*, p. 753.) The resin, constituting about 60 per cent., is very soft, and dissolves in ether or in alkaline liquids, even in milk of lime, but only partially in carbon disulphide. When heated with hydrochloric acid for some time, it yields umbelliferone. If a small fragment of galbanum be immersed in water, a fluorescence will be produced by a drop of ammonia. Asafetida shows the same reaction, but ammoniac does not.

Galbanum submitted to dry distillation yields a thick oil of brilliant blue color. This oil on rectification yields a greenish portion, and then a superb blue oil. Kachler (*B. Chem. G.*, 1871) found a colorless oil, $C_{10}H_{16}$, and a blue oil, $C_{10}H_{16}O$, which agreed with the blue oil of the flowers of

Matricaria Chamomilla. By fusing galbanum resin with potassium hydroxide, Hlasiwetz and Barth (*Ann. Ch. Ph.*, cxxx, p. 354) obtained resorcinol, together with acetic and volatile fatty acids.

Galbanum was known to the ancients. It is stimulant, expectorant, and antispasmodic, and is considered as intermediate in power between ammoniac and asafetida. It was formerly used in chronic affections of the bronchial mucous membrane, *amenorrhea*, and *chronic rheumatism*, but is now used chiefly in the form of plasters as an external stimulant.

Compound pills of galbanum were official in the British Pharmacopœia, 1898, under the name of *Pilula Galbani Composita* (formerly *Pilula Asafœtida Composita*) consisting of equal parts of galbanum, asafetida and myrrh, syrup of glucose being used as excipient.

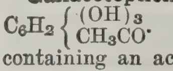
Dose, from ten to twenty grains (0.65 to 1.3 Gm.), given in pill, or triturated with gum arabic, sugar and water, so as to form an emulsion.

Under the name of *Zalou root* there appears in the Bayrout markets the root of the *Ferula Hermonii* Boiss. This contains, according to Guiges (*P. J.*, 1906, p. 65) a resin which differs from Galbanum in that it gives with hydrochloric acid a green color, which disappears on heating. It is used by the people of that section as an aphrodisiac.

Galium. *Galium Aparine* L. *Cleavers. Goosegrass. Grateron. Rièble*, Fr. *Klebkraut*, G.—This is a delicate annual, succulent, rubiaceous plant, indigenous to Europe and Asia and naturalized in the United States, growing along the seashore and in shaded ground inland. It possesses quadrangular, reclining stems that are hairy at the nodes and bristle-prickly, lanceolate leaves that are arranged 8 in a whorl, and small white flowers on axillary stalks. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. Schwartz found in it a variety of tannic acid, which he named *galitannic acid*, citric acid, and a peculiar acid, previously discovered by Schwartz and Rochleder, and named *ribichloric acid*, $C_{14}H_8O_9$. (*P. J.*, xii, 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in *dropsy, congestion of the spleen, scrofula, scorbutic eruptions*, and *lepra.* Orwin (*T. G.*, vol. i, 767) commends it highly in *psoriasis.* Three ounces (90 cc.) may be given twice a day.

Galium verum L. *Yellow Ladies' Bedstraw. Cheese Rennet. Caille-lait jaune*, Fr. *Megerkraut, Liebfrauenstroh*, G.—This is a perennial species of Galium (Fam. *Rubiaceæ*) which is indigenous to Europe but found in northeastern United States and lower Canada. It differs from the former species in having erect, smooth stems, linear leaves and yellow flowers, the latter arranged in dense panicles. It is inodorous, but has an astringent, acidulous, bitterish taste. The bruised plant is sometimes used to color cheese yellow, being introduced into milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red, and the plant, eaten by animals, colors the bones like madder. Schwartz found the same principles in it as in *G. Aparine.* It was formerly highly esteemed as a remedy in *epilepsy* and *hysteria*, and was applied externally in *cutaneous eruptions*, in the form either of the recently expressed juice or of a decoction from the fresh plant. Of the American species, *G. tinctorium* L. is closely allied in properties to *G. verum.* It is said to be useful in *cutaneous diseases*, and the root is employed by the Indians for staining their feathers and other ornaments red. *G. triflorum* Michx. contains coumarin, as pointed out by L. von Cotzhausen. (*A. J. P.*, 1876, 405.)

Gallacetophenone. *Alizarine Yellow. C.*—



$C_6H_2\begin{cases}(OH)_3\\ CH_3CO\end{cases}$. This is a derivative of pyrogallol, containing an acetyl group replacing an H atom of the benzene nucleus. Forms a pale yellow powder, crystallizing from hot water, in which, as well as in alcohol and ether, it is readily soluble. It is also soluble in glycerin. This substance has been proposed as a substitute for pyrogallic acid in the local treatment of *psoriasis*, it being claimed that it does not stain, and is not so poisonous as the acid.

Gallic Acid.—*Acidum Gallicum. U. S. IX. Trioxybenzoic Acid. Dioxysalicylic Acid. Trihydroxybenzoic Acid. Acide gallique*, Fr. Cod.; *Gallussäure*, G. *Acido gallico*, It. *Acido agallico*, Sp. $C_6H_2(OH)_3.COOH$. Gallic acid was dropped from the Br. at the 1914 revision and from the X revision of the U. S. It was first prepared by Scheele in 1786. Gallic acid is made by the decomposition of tannic acid either through the effect of living ferments or by the action of strong acids. The method of the U. S. P. of 1870 was based upon the spontaneous decomposition of tannic acid when exposed to the air. The British Pharmacopœia of 1885 employed a process based upon the decomposition of tannic acid by sulphuric acid. Fernbach (*C. R. A. S.*, 1900, cxxxi, 1214) found that a tannin splitting ferment *tannase* is present in *Pencillium*, and Pottevin (*C. R. A. S.*, 1900, cxxxi, 1215) isolated a similar ferment from *aspergillus.* This accounts for the conversion of the tannic acid into gallic acid when galls are moistened and allowed to stand, for they always become moldy during the process, and explains the sweated gallic fermentation of Robiquet and LaRoque.

Gallic acid is *trioxybenzoic acid* or, more properly speaking, 3:4:5 *trihydroxybenzenecarboxylic acid.* It is monobasic. Unlike tannin it does not precipitate alkaloids from their solutions.

Gallic acid is in "white, or pale fawn-colored, silky, interlaced needles, or triclinic prisms; odorless; having an astringent and slightly acidulous taste; permanent in the air. One Gm. of Gallic Acid dissolves in 87 mils of water, 4.6 mils of alcohol, 10 mils of glycerin, and in about 100 mils of ether at 25° C.; also in about 3 mils of boiling water; almost insoluble in chloroform. A saturated aqueous solution of Gallic Acid is acid to litmus. Add 6 drops of sodium hydroxide T.S. to 5 mils of a cold, saturated aqueous solution of the Acid; a deep green color gradually develops, which is changed to reddish or brownish-red by acids. Gallic Acid neither colors nor precipitates solutions of pure ferrous salts, but it forms a bluish-black precipitate with ferric salts. When dried to constant weight at 100° C., the Acid loses not more than 12 per cent. of its weight. Incinerate about 1 Gm. of Gallic Acid; not more than 0.1 per cent. of ash remains. A cold saturated aqueous solution of Gallic Acid yields no precipitate with gelatin T.S. or starch T.S. (*tannic acid*)." *U. S. IX.*

It produces a deep bluish-black color with solutions of ferric salts, which disappears when the solution is heated, a result which Mahla has shown to depend on the conversion of the gallic into *pyrogallic* or *metagallic acid* (pyrogallol) by the loss of carbon dioxide. Gallic acid does not precipitate gelatin, or a solution of ferrous sulphate.

By the action of arsenic it is converted almost entirely into tannic acid without the production of arsenous acid. (Schiff, *Chem. News*, xxix, 73.) Young's test, potassium cyanide, gives a reddish color with gallic acid and none with tannic acid. A mixture of ammonium chloride and ammonia produces a red coloration, but no precipitate, in gallic acid solution; while in tannic acid solution it produces a whitish precipitate rapidly turning reddish-brown. (*A. J. P.*, April, 1889.) A test proposed by Flückiger consists in adding to the solution of gallic acid a diluted (1 to 100) solution of pure ferrous sulphate. To the colorless solution a little sodium acetate is to be added, when a deep violet color will appear, due to the formation of ferrous gallate. Heated to 216° C., gallic acid gives off carbon dioxide, and is changed into *pyrogallic acid.*

Uses.—Gallic acid differs essentially from tannic acid in that it does not coagulate albumen. It is readily absorbed from the intestinal tract and eliminated through the kidneys. Its presence in the urine can be demonstrated by the addition of a soluble ferric salt after acidulation of the urine with hydrochloric acid. The older writers attributed astringent properties to gallic acid, although less active than those of tannic acid, but as the modern conception of the action of astringent drugs is that their effects depend upon the precipitation of albuminous matters this view must be regarded with doubt. Nevertheless it is used to a considerable extent by many physicians as an internal styptic, for example, in *hematuria* or *hemoptysis.* It is also asserted that it will lessen the quantity of albumen in the urine in cases of *nephritis.* Gallic acid is incompatible with solutions of alkali hydroxides and carbonates with which it combines to produce colors ranging from green to yellow, red, and brown. With lime water it gives even more marked color changes and produces a blue precipitate. With ferrous salts no change occurs, but as soon as oxidation begins or with ferric salts direct, an inky color is produced. It acts as a reducing agent with salts of silver and gold, and with iodine, arsenates, permanganates, etc. With lead salts and some other metallic salts it produces precipitates.

Dose, five to twenty grains (0.32–1.3 Gm.).

Gallicin. *Methyl Gallate. Methyl Ester of Gallic Acid.* $C_6H_2(OH)_3.COO.CH_3$.—This product is made by the interaction between warm solution of tannin in methyl alcohol and hydrochloric acid gas. It forms rhombic prisms or fine needles melting at 202° C., soluble in hot water, ether and alcohol. It is a non-toxic antiseptic and is used in *conjunctivitis, keratitis,* and other ocular inflammations, as an antiseptic dusting powder.

Gallinol. *Gallanol. Gallanilide.* $C_6H_2\text{-}\left\{\begin{matrix}CO.NH.C_6H_5\\(OH)_3+2H_2O\end{matrix}\right.$.—This anilide of gallic acid is formed by boiling tannin with aniline, and was brought forward by Cazeneuve and Rollet as a local remedy to replace chrysarobin in the treatment of skin diseases. (*C. R. A. S.*, 1893.) It occurs in colorless crystals melting at 205° C., of a bitter taste, soluble in hot water, ether, and alcohol, insoluble in benzene and chloroform. It has been especially commended by Gonon, Bayet, Max Joseph, and others, not only in *psoriasis,* but also in chronic *eczema,* to be used in a 10 per cent. solution or ointment, or sometimes in very advanced cases as high as 20 per cent.; it is affirmed never to produce irritation. The removal of the hair is not necessary, provided the skin be thoroughly cleansed with alkaline soap solutions.

Gallobromol. *Dibromgallic Acid.* $C_6Br_2(OH)_3COOH$.—A light brown powder composed of fine needles melting at 205° C.; soluble with difficulty in cold water, easily soluble in hot water, alcohol, and ether, and having a strong acid reaction and a slightly bitter taste. It has been used by Lépine in *neurasthenia* and *epilepsy* to replace potassium bromide, but it would seem to be a somewhat dangerous remedy, as in Lépine's experiments a dog weighing 11 kilogrammes was killed in two hours by 11 Gm. According to Stein, it is to dogs more poisonous than the sodium bromide, less than the potassium bromide. In the dog small doses produce a primary moderate rise of the blood pressure, followed by fall of pressure, with cardiac arythmia. It has also been used as a local application in *cystitis* and *skin diseases.* It is incompatible with alkalies or alkaline salts, and iron compounds. *Dose* (Lépine), as a sleeping potion, forty-five grains (3 Gm.); in *epilepsy,* from thirty to forty-five grains (2–3 Gm.) a day. (See *Cb. G. T.*, xiii, 1895.)

Gallogen. *Ellagic Acid.* $C_{14}H_6O_8$.—This is a yellowish powder devoid of odor and taste, insoluble in an acid or neutral fluid, but soluble in alkaline fluids. In solution it shows the characteristic tannic acid reactions. With nitric acid containing nitrous acid it gives a characteristic dark red color. It is employed as an intestinal astringent in all forms of *diarrhea. Dose,* adults fifteen grains (1 Gm.) several times a day; for children, five to eight grains (0.32–0.5 Gm.) several times a day.

Gallols.—E. Kromayer (*Monatshefte für Prakt. Dermatologie,* vii) has tested as remedies for diseases of the skin a number of chemical combinations of pyrogallol, chrysarobin, and resorcinol, with various acids. Of these a few give promise of therapeutic usefulness.

Lenigallol. Pyrogallol Triacetate. $C_6H_3(CH_3CO_2)_3$.—This is a white powder, insoluble in water, and is used in paste form. This derivative of pyrogallic acid has been highly commended as a local remedy in acute and moist *eczema,* and in *pityriasis rosea.* It is said not to act well in the dry desquamating eczemas. It is generally applied in the form of a paste containing from 2 to 5 per cent. of *lenigallol.* In the strength of 30 to 50 per cent. it is also useful as a keratolytic. It is slowly soluble on warming with aqueous solutions of alkalies, with decomposition.

Eugallol, pyrogallol monoacetate, is a very thick, syrupy, transparent, dark yellow mass, readily soluble in water. Marketed only in a 66 per cent. solution in acetone.

These substances are stated not to be affected by contact with healthy skin, but to be slowly decomposed by the diseased skin with the liberation of pyrogallol. Strong ointments of lenigallol are to be employed in *psoriasis,* 1 or 2 parts of lenigallol to 200 parts of zinc paste in *eczemas.* Even the most acute eczemas, as well as those with impetiginous crusty exudations, are reached by the ointment.

Eugallol produces great local excitement, and is only to be employed in the most obstinate cases of *psoriasis.* Under such circumstances, however, the direct local application as a paint, daily or every other day, produces a marked inflammation, under which the most stubborn patches are said to disappear. Dusting the painted parts with zinc oxide before drying makes the action more vigorous. The value of eugallol has been strongly confirmed by Paul Gruneberg (*Derm. Zeit.*, vi, 1899), who uses in *lupus* a zinc paste with from 11 to 12 per cent. of eugallol continuously applied after free curetting, and in *psoriasis* a 33½ per cent. acetone solution followed by zinc oxide dressing.

Galyl.—This arsenic compound is said to be *tetroxy-diphospho-amino-diarseno-benzene* with the empiric formula $C_{24}H_{22}O_8N_4P_2As_4$. It is asserted to possess curative properties in *syphilis* similar to those of salvarsan (see Dudley, *L. L.*, July 8, 1916) and to be decidedly less toxic (Pearce and Brown, *J. Ex. M.*, 1915, p. 517). It has also been recommended by Falconer and Anderson (*L. L.*, 1917, ii, 486) as an adjuvant to quinine in obstinate *malarial fevers.* It is given in *doses* of from three to six grains (0.2–0.4 Gm.) injected intravenously or intramuscularly, at intervals of from three to seven days until a total of about thirty-two grains (2.0 Gm.) has been administered.

Gardenia. *Gardenia grandiflora* Lour. (Fam. *Rubiaceæ.*)—A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins, and according to Lorenz Mayer, contains *crocin* (see *Crocus*). The fruit of another species, *G. campanulata* Roxb., growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, *Flor. Med.*, 434.)

Garrya Fremontii Torr. *California Fever Bush. Skunk Bush.*—A shrub belonging to the *Cornaceæ,* indigenous to California and Oregon. Its leaves are ovate or oblong, acute, yellowish-green. Its flowers are borne in dense axillary spikes and its fruit is a 1–2 seeded berry. The leaves are intensely bitter, and were formerly esteemed tonic and antiperiodic. D. W. Ross (*A. J. P.*, 1877) states that he found in them a new alkaloid, *garryine.* The *dose* of the fluidextract of the leaves is from ten to thirty minims (0.6–1.8 cc.).

Gaultheria. *Wintergreen. Boxberry. Teaberry. Checker-berry. Gaulthérie couché, Paloninier, Thé du Canada, Thé de Terreneuve,* Fr. *Canadischer Thee, Bergthee,* G.—*Gaultheria procumbens* L. (Fam. *Ericaceæ*) is a small indigenous, woody, evergreen plant. The leaves, which were formerly official in the U. S. Pharmacopœia, are short-petiolate, obovate or oval, about 4 cm. in length and 2 cm. in breadth, acute, revolute, obscurely serrate at the edges, coriaceous, shining, bright green above, paler beneath, of unequal size, and supported irregularly on short red petioles.

The plant extends from Newfoundland and Manitoba southward, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees. The white, nodding flowers appear from July to August, singly in the leaf axilla and the red, baccate fruit ripens at corresponding periods. To the very peculiar aromatic odor and taste which belong to the whole plant the leaves add a marked astringency. The aromatic and medicinal properties of wintergreen reside exclusively in their volatile oil. (See *Methylis Salicylas.*)

Gelanth. *Gelanthum.*—*Gelanth* is a combination of equal weights of tragacanth and gelatin, prepared by Unna as a basis for various pastes for the skin. It is stated to be superior to the older pastes in drying more quickly and leaving a smoother coating upon the skin, as well as in holding more uniformly and in tighter suspense the drug used with it, and in not spoiling readily. It is made by allowing tragacanth to soften with twenty times its mass of water for four weeks, then warming the mass to fluidity with steam and pressing it through a mill. In the meanwhile gelatin has been softened in the water and then for some time exposed to a high pressure of steam in Unna's boiler, which exposure lessens its capability of gelatinization. The mixture of the two masses is allowed for two days to soften in the steam, then passed through a mill and mixed with 5 per cent. of glycerin, a little rosewater, and 2 per cent. of thymol. The finished gelanth contains about 2½ per cent. each of dry gelatin and tragacanth. In using it as a vehicle, fatty matters must first be emulsified and insoluble substances rubbed up with water to a soft paste before they are mixed with gelanth.

Genista. *Genista tinctoria* L. *Dyers' Broom. Dyers' Weed. Green Weed. Woad-Waxen. Genet des Teinturiers,* Fr. *Färberginster,* G. (Fam. *Leguminosæ.*)—A low shrub, growing wild in Europe, and established on sterile hills and roadsides from Maine to New York, cultivated in greenhouses in this country on account of its profusion of yellow leguminous flowers. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the *dose* of a drachm and a half (5.8 Gm.). By some authors they are said to be diuretic and to be useful in *dropsy.*

Gentian Violet.—*N. N. R.* 1925. This is a trade name of *methyl violet* which is a mixture of the hydrochlorides of penta- and hexamethyl-pararosaniline, $C_{19}H_{12}(CH_3)_5N_3HCl$ and $C_{19}H_{11}(CH_3)_6N_3HCl$. A proprietary form of the same chemical is known under the name of *Pyoktanin.* It is a green crystalline powder, soluble in about 20 parts of water, alcohol or glycerin. It is insoluble in petroleum fractions.

Boer called attention many years ago to the extraordinary difference in the susceptibility of various species of bacteria to the disinfectant action of this dye. In 1912 Churchman (*J. Ex. M.*, 1912, xvi, and *J. Ex. M.*, 1921, xxxiii, p. 569) showed that in very dilute solution (1 to 100,000) it inhibits the growth of "Gram-positive" organisms (that is, bacteria which are not decolorized by Gram's iodine solution), but does not affect "Gram-negative" bacteria nor human tissue cells. The "Gram-positive" group of bacteria includes the diphtheria bacillus, the staphylococcus pyogenes, the gonococcus, etc. On the basis of these effects he injected a saturated aqueous solution into the joint cavity in cases of gonorrheal and staphylococcic *arthritides* with great benefit (see *J. A. M. A.*, 1920, lxxv, 1921, lxxvii, p. 24). Smith and Casparis (*J. A. M. A.*, 1923, lxxxi, p. 2184) and later Young and Hill (*J. A. M. A.*, 1924, lxxxii, 672) have employed it with brilliant results in cases of staphylococcus *septicemia.* They used *doses* of from 2 to 5 milligrammes per kilo of body weight. It has been used to a considerable extent in veterinary practice; Klein (*Berlin. Tierartz. Wochens.*, 1911) and others have reported favorably on the value of pyoktanin in *foot and mouth disease.* It is also used in *doses* of one to eight grains (0.065–0.5 Gm.) in the treatment of *cholera* and *carcinoma.*

According to Fühner (*A. E. P. P.*, 1908, lix, p. 161), methyl violet has an effect upon the heart similar in kind to that of digitalis, and *methyl green*, which is prepared from methyl violet, has no effect upon the heart, but acts upon the peripheral motor nerves as does curara.

Germanium. (Ge–72.5.)—This element was discovered in 1886 by Winkler in the silver-containing mineral argyrodite which contains germanium to the extent of 6 or 7 per cent. He named it for his native country as argyrodite had just been discovered near Freiburg in 1885. Germanium has since been found in several other rare minerals including Canfieldite and Euxenite. The element germanium is a grayish white metal having a fine luster and crystallizing in octahedra. It melts at about 900° C. and has a specific gravity of 5.46. It forms two classes of salts corresponding to the oxides GeO and GeO_2.

Germanium dioxide is a white powder soluble in alkalies but almost completely insoluble in acids.

Hammett and Nowrey (*J. Ex. M.*, 1922, xxxv, p. 507 and *J. P. Ex. T.*, 1922, xix, p. 337) have shown that *germanium dioxide* has remarkable power of stimulating the formation of red blood cells. The histological examination of animals which had received the drug led to the inference that the increase in the number of corpuscles was due to a stimulating influence upon the bone marrow; there was no evidence of any destruction of red blood cells nor any action upon the spleen. They found also that the agent is of very low toxicity, rats surviving doses up to 180 milligrammes per kilo. These results naturally suggest the use of this agent in *anemia.* It has been used clinically by Lenker (*Penna. Med. J.*, 1922, xxvi, p. 86) and by Kast (*J. Lab. Clin. M.*, 1922, vii, p. 643) and others in the treatment of various types of *anemia.* Lenker concludes that in secondary anemia its beneficial effects are very positive; in *pernicious anemia* it caused more or less temporary improvement and he classes its effect in this disease with that of arsenic. Alexander (*A. J. M. S.*, 1923, clxvi, p. 256) found the results in pernicious anemia less satisfactory than those of iron cacodylate.

Although Kast administered the drug by mouth, most of those who have used it employed it hypodermically. Lenker recommends that the aqueous solution be neutralized with sodium hydroxide for hypodermic injection. In this case it is manifest that sodium germanate will be formed. Nowrey (*J. H. H. B.*, 1922, xxxiii, p. 341) has experimentally found that solutions of *sodium germanate* are efficacious. The solutions are injured by boiling.

The *dose* of germanium dioxide recommended is from one-third to two-thirds of a grain (0.02 to 0.04 Gm.) daily. Kast gave by mouth from one and one-half to three grains (0.1 to 0.2 Gm.) daily for two or three days.

Geum. *Water Avens. Radix Caryophyllatæ Aquaticæ. Radix Benedictæ Sylvestris. Racine de Benoîte aquatique* (*de Benoîte des Ruisseaux*), Fr. *Sumpfnelkenwurzel, Wasser-Benedikten-Wurzel*, G.—Several species belonging to this rosaceous genus have been medicinally employed, but three or four are deserving of particular notice—*Geum rivale* L., which once had a place in the U. S. Secondary List, *G. urbanum* L., formerly recognized by the Dublin College, *G. virginianum* L., an indigenous species, the root of which has been recommended in *dysentery* by W. A. Gibson (*Med. Rec.*, 1868), and *G. canadense* Jacq. (*G. album* Gmel.), recommended by W. A. Spurgeon in *gastric irritation* and *headache.* (*A. J. P.*, 1883.)

The rhizome of *Geum urbanum* L. is from 3 to 7 cm. in length and about 8 mm. in thickness. It is more or less branching, having on the upper surface the remains of the short stems and petiole-bases and on the lower surface numerous fibrous roots. Externally it varies from a brownish to a brownish-yellow and internally it is dark brown. The fracture is short. When quite dry it is nearly inodorous, but in the recent state has an odor like that of cloves, whence it is sometimes called *radix caryophyllatæ.* The taste is bitterish and astringent. It imparts its virtues to water and alcohol, which it tinges red. Buchner obtained a yellow, amorphous, neutral, bitter-tasting mass, which he calls *geum-bitter.* Distilled with water it yields 0.04 per cent. of a thick, greenish-yellow volatile oil, consisting chiefly of eugenol, a tasteless resin, gum, bassorin, and starch. It has been much used in Europe as a tonic and astringent, in chronic and passive *hemorrhages, chronic dysentery* and *diarrhea, leucorrhea, intermittent fever,* etc. The *dose* is from thirty grains to a drachm (2.0–3.9 Gm.) of the powder three or four times a day, or an equivalent quantity in decoction.

Geum rivale L.—*Water* or *purple avens,* a plant growing in bogs and wet places in the northern United States, has a perennial, horizontal, jointed, scaly, tapering root, about 15 cm. long, of a reddish-brown color externally, white internally, and furnished with numerous descending yellowish fibers. The dried root is hard, brittle, easily pulverized, reddish or purplish, without odor, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Water avens possesses similar therapeutic properties to avens, for which it is sometimes substituted, but is less esteemed. The *dose* of the powdered root is from twenty grains to a drachm (1.3–3.9 Gm.), to be repeated three times a day. A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee.

Gillenia. *Racine de Gillénie,* Fr. *Gillenienwurzel,* G.—Under this name the U. S. P. formerly included in its Secondary List the roots of two species of *Gillenia.* (Fam. *Rosaceæ.*)

Gillenia trifoliata (L.) Moench. or *Bowman's Root* is a perennial herb whose underground portion consists of a rhizome having numerous long slender roots. The leaves are trifoliate with ovate-oblong, cut-serrate leaflets and small awl-shaped stipules. It grows throughout the United States, east of the Mississippi. The root should be gathered in September. (See *A. J. P.*, 1898, 501.)

G. stipulata (Muhl.) Trel., commonly known as *Indian-Physic* or *American Ipecac,* also a perennial herb, differing from the preceding species in possessing lanceolate, deeply cleft leaves with large leaf-like, doubly incised stipules. It grows as far north as the state of New York, and extends as far west as Kansas. Its root is precisely similar to that of the eastern species, and is reputed to possess the same properties.

The roots of *G. stipulata* resemble those of

Ipecac, the bark being thinner and enclosing in the inner layers numerous reddish resin cells. The roots of *G. trifoliata* are smaller and indistinctly annulate, exhibiting few or no distinct fissures. For microscopic characters, see G. L. Curry. (*Am. Pract. and News*, May, 1892.) The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish color, and possesses a feeble odor, which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires a red color. The root yields its bitterness also to alcohol. *Gillenin* of W. B. Stanhope was a whitish substance, very bitter, slightly odorous, permanent in the air, soluble in water, alcohol, ether, and the dilute acids, and neutral to test paper. Nitric acid rendered it blood-red, chromic acid green. Tannic acid produced no effect. It gave white precipitates with potassium hydroxide, lead subacetate, and tartar emetic. Half a grain (0.032 Gm.) of it produced nausea and retching. (*A. J. P.*, xxviii, 202.) G. L. Curry (*A. J. P.*, 1892, 513) has found two glucosides: the first, *gillein*, obtained from the ethereal extract, formed white feathery crystals, was colored red by sulphuric acid, yellow by nitric acid, and deepened the color of chromic acid; the second, *gilléenin*, obtained from the aqueous infusion, was amorphous, of yellowish color, of faint taste at first but becoming very bitter, and giving no color reactions with the acids.

Gillenia is a mild and efficient emetic, and, like most substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to be tonic, and has been used as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnæus was aware of its reputed virtues. *Dose* of the powdered root, as an emetic, from twenty to thirty grains (1.3–2.0 Gm.).

Ginseng. *Panax quinquefolium* L. *Panax. U. S.* 1870. *Ginseng*, Fr. G., Sp. *Ginsen*, It.—*American ginseng* is a perennial herb belonging to the *Araliaceæ.* It is indigenous to eastern North America and grows in rich, cool woods, especially along the mountains, from Quebec and Ontario, south to Georgia. The plant is characterized by its large, aromatic, spindle-shaped, often forked root, its solitary stem bearing a single whorl of 3 palmate leaves, each of which usually has 5 ovate-oblong leaflets, its terminal umbel of greenish-white flowers and its red berry fruits. The root is the part employed. It is not used in America, but is exported to China. While supplied with *ginseng* exclusively from their own country, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin, and the first shipment from North America to Canton yielded enormous profits. John Henry Wilson (*P. J.*, July, 1888) states that there are in the Chinese market five ginsengs, four of them of Asiatic origin, derived from *Panax Ginseng* C. A. Meyer, the fifth, the American ginseng, from *Panax quinquefolium.* According to E. M. Holmes, *T'angshên,* which is used by the poor of China as a substitute for the costly ginseng, is a root of a campanulaceous plant, *Codonopsis Tangshen,* and is exported from Hankow and Oo-chang to the extent of five hundred tons annually. (*P. J.*, xxi.) For an account of the Chinese methods of using ginseng, see *P. J.*, vi, 86.

On account of the growing scarcity of the American ginseng plant, it is now cultivated quite extensively, but many precautions are necessary for success. The cultivated roots were larger than those of the wild plant. For an account of the ginseng cultivation in Corea, see *P. J.*, 1885, 732; and of its collection in the United States, see *D. C.*, 1884, 33. (For details of culture and preparation, see *Bulletin 62, Pennsylvania State Agricultural Experiment Station; Bulletin No. 16, Division of Botany, U. S. Department of Agriculture; Proc. A. Ph. A.*, 1901, p. 90; *Ph. Era*, 1900, p. 581; 1903, p. 497; *P. J.*, 1904, p. 652.)

The root is fleshy, somewhat spindle-shaped, from 5 to 12 cm. long, and 1 to 2.5 cm. thick, often bifid or trifid, occasionally having a remote resemblance to the human figure, from which circumstance it is said the Chinese name *ginseng* originated. Externally it is yellowish-white to yellowish-brown, annulate and longitudinally wrinkled. Its fracture is short, exhibiting a soft, thick, mealy bark containing many reddish oil and resin cells and a central yellowish wood with narrow wedges and broad medullary-rays.

Ginseng has a feeble odor, and a sweet, slightly aromatic taste, somewhat analogous to that of licorice root. It contains a glucosidal principle, *panaquilon,* besides saponin, a bitter principle, a volatile oil, resin, sugar, mucilage and starch. S. S. Garrigues gives the formula for panaquilon as $C_{12}H_{25}O_9$. It is an amorphous, yellow powder, soluble in water and alcohol, but not in ether, of a sweet bitterish taste, and has the characteristic property that, when treated with strong acids, it is converted into a white substance, insoluble in water, with the escape of carbon dioxide and water. Garrigues proposed for this white substance the name of *panacon,* $C_{11}H_{19}O_4$. (*A. J. P.*, xxvi, 511.) Davydow (*A. J. P.*, 1890, 338) investigated these principles discovered by Garrigues, but adds nothing new to our information concerning them. W. Sakai states that the ether soluble fraction of ginseng contains the active principle, and that the volatile oil has a density of 0.925 and consists mainly of *panacen* $(C_5H_8)n$, which increases the blood pressure and the rate of respiration. An unsaturated acid of high molecular weight is also present both in the free state and as an ester. He states that the resin is physiologically inert. Kondo and Yamaguchi obtained 10 Gm. of this same volatile oil from 18 kilos of Japanese ginseng. They also isolated a phytosterol and several fatty acids.

The extraordinary medicinal virtues formerly ascribed to ginseng had no other existence than in the imagination of the Chinese. It is little more than a demulcent, and in this country is rarely employed as a medicine. Sakai (*Sei-I-Kwai*, 1917, xxxvi, p. 113) from physiological experiments concludes that ginseng has a sedative effect upon the cerebrum and a mildly stimulating action upon the vital centers. Some persons are in the habit of chewing it, having acquired a relish for its taste, and it is sold chiefly to supply the wants of these.

Glaucium. *Glaucium flavum* Crantz. (*G. luteum; G. Glaucium* Karst.) *Yellow Horned*

Poppy. Sea Poppy. Bruiswort. Pavot cornu, Fr. *Hornmohn,* G. (Fam. *Papaveraceæ.*)—An annual or biennial plant with clasping cauline leaves and solitary yellow or orange flowers indigenous to Europe and sparingly naturalized in waste places from New England to Virginia. In contains a saffron-colored, milky juice. The stems and leaves, according to Fischer (*A. Pharm.*, 1901, ccxxxix, p. 426), contain two alkaloids—*glaucine* and *protopine*—while the root contains besides protopine traces of chelerythrine and sanguinarine (see under *Sanguinaria*). Glaucine has also been studied by Gadamer (*A. Pharm.*, 1911, ccxlix, 680); it has the formula $C_{21}H_{25}O_4N$, and forms yellow crystals. Maepmann and Helt recommended the plant in the treatment of *diabetes* (*Med. Neuigkeiten d. Pharm-Post.*, 1899, 346).

Glechoma. *Nepeta hederacea* (L.) Trevisan (*N. Glechona* Benth.). *Herba Hederæ Terrestris. Lierre terrestre,* Fr. *Gundermann, Gundelrebe,* G. *Ground-ivy. Gill-over-the-ground.*—A small perennial creeping herb (Fam. *Labiatæ*), with roundish kidney-shaped leaves and light blue flowers indigenous to Europe and widely naturalized in the United States, and growing in damp, shady, grassy places, as in orchards and along fences and hedges. The herb was formerly official, and still enjoys some credit as a domestic remedy. It has a peculiar, disagreeable odor, and a bitter, somewhat aromatic taste, and imparts its properties to boiling water. It was formerly used in chronic *pulmonary* and *urinary catarrhs.* From a half drachm to a drachm (2–3.9 Gm.) was usually given in infusion as a dose.

Gleditschine.—*Gleditschia triacanthos* L., or *Honey Locust,* and *G. Macracantha* Desf. (Fam. *Leguminosæ*), are small, thorny trees having pinnate leaves, small spikes of inconspicuous, green flowers, and elongated pods containing flat seeds and a sweet pulp. The former grows in rich woods in the eastern and central United States and is common in cultivation; *G. Macracantha* is indigenous to China. These trees were chemically studied by B. F. Lautenbach (*P. M. T.*, 1878), who abstracted from them an alkaloid, which he found to produce in the frog stupor and loss of reflex activity, due to an action upon the spinal cord. To this alkaloid Lautenbach gave the name of *gleditschine.* In 1887 a solution asserted to contain an alkaloid *stenocarpine,* which was asserted to be obtained from the *Gleditschia triacanthos,* was brought forward as a local anesthetic. This solution was shown by Marshall (*Phila. Med. News,* 1888) and others to contain 6 per cent. of cocaine, besides some atropine or other mydriatic alkaloid. (See also *A. J. P.*, 1887, 589.)

Glidin.—Glidin is an albuminous preparation made from wheat flour and is asserted by Loeb (*Med. Klin.*, 1905–1906, p. 625) to represent 98 per cent. of albumin and 1 per cent. of lecithin. While it has been used to a slight extent as a nutrient, its greatest interest lies in the fact that it forms chemical combinations with various irritant drugs. An examination of glidin by Coblentz showed 30 per cent. albumin, 2 per cent. nutritive salts and 68 per cent. carbohydrates, varying greatly from Loeb's analysis.

Arsen-glidin (*Arsan*) is a yellowish-gray powder insoluble in water but dissolving with a yellow color in alkalies. It represents about 4 per cent. of arsenous acid. It is generally administered in the form of tablets, each of which represents one thirty-second of a grain (0.002 Gm.) of arsenic.

Bromo-glidin is a brownish, odorless, almost tasteless powder, sparingly soluble in water and is used in the same manner as the inorganic bromides. The *dose* is eight to fifteen grains (0.5–1.0 Gm.). Another of these compounds is *iodoglidin* which is recommended in *doses* of fifteen to forty-five grains (1.0–3.0 Gm.) per diem in the various conditions in which iodine has been employed. It is a dark, yellow powder, said to contain 10 per cent. of iodine, and according to Boruttan (*D. M. W.*, 1907, p. 1490) it is much more slowly absorbed than the inorganic iodides.

Globularia. *Globularia Alypum* L. *Wild Senna* of Europe. (Fam. *Globulariaceæ.*)—This is a small shrub indigenous to the European shores of the Mediterranean. Its leaves have been occasionally used as a cathartic since the Middle Ages. Heckel and Schlagdenhauffen obtained from the leaves *globularin,* $C_{15}H_{20}O_8$, an amorphous glucoside which splits by treatment with mineral acids into glucose and *globularetin,* C_9H_6O. *Globularia vulgaris* L. was found to contain the same substances. (*J. P. C.*, 1883, 361.) It is asserted that globularin is a vasomotor constrictor which acts especially upon the renal arteries. Jaksch (*R. T.*, 1910, p. 596) has observed diminution of the quantity of urine in *diabetes insipidus,* also of *diabetes mellitus,* after the administration of the glucoside. The *dose* of globularin is one-half to one grain (0.03–0.065 Gm.) daily. It does not diminish the excretion of sugar. Globularetin, a brownish-yellow powder, has also been used in medicine as a diuretic and purgative, although no definite information can be found regarding either its efficiency or its manner of use. *Dose,* of Globularia, according to Planchon, one ounce (31 Gm.), in decoction.

Gloriosa. *Gloriosa superba* L.—This plant, commonly known as *Climbing Lily* (Fam. *Liliaceæ*) is found in the forests of tropical Africa and Asia. It possesses ovate-lanceolate leaves, and its flowers, while opening yellow, later become yellowish-red and deep scarlet. The roots, stalk, and leaves are said to be an acrid narcotic poison, and not infrequently used for suicidal purposes in India. Gloriosa contains according to Warden a poisonous alkaloid *superbine* (*P. J.*, xi, 496) and two resins. Clewer, Green and Tutin (*Tr. Chem. Soc.*, 1915, cvii, p. 835) report also the presence of colchicine and another base—possibly methylcolchicine—and choline.

Glue.—An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it until, upon cooling, it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. It differs from gelatin in containing a larger proportion of glutin and a smaller amount of chondrin. Glue, when of good quality, is hard and brittle, of a color varying from light yellow to brown, and equally transparent throughout. It softens and swells very much in cold water, without dissolving, but is readily dissolved by hot water. It is soluble in large proportion of glycerin, and with heat forms with it in smaller proportion a jelly. It is employed chiefly for cementing wood.

An elastic and imputrescible preparation of glue may be made by dissolving glue in water by means of a water bath, concentrating the solution, then adding a weight of glycerin nearly equal to that of the glue employed, thoroughly mixing, evaporating the excess of the water, and finally pouring into molds, or on a marble slab. It has been used for the preparation of artificial anatomical specimens. The various *hectograph compositions* introduced for copying purposes are similar mixtures. One of the best copying masses is made by dissolving one part of glue or gelatin in a mixture of two parts of water and four parts of glycerin, with a few drops of phenol, heating, straining, and adding three parts of sifted whiting or terra alba. (See *N. R.*, 1879, 338, 364.) A good *liquid glue* may be made by mixing two pints of distilled water, sixteen ounces of the best white glue and four ounces of dry white lead, heating upon a water bath until homogeneous, then adding four fluidounces of alcohol, and continuing the heat and the agitation for a few minutes. The mixture is to be poured into bottles while still hot. A liquid glue may also be prepared by mixing in a stoppered bottle 38 parts of glue properly divided, and 100 parts of 36 per cent. acetic acid. On exposure the acid evaporates, leaving the glue unchanged. (*J. P. C.*, 3e sér., xlvi, 35.) Knaff prepares *strong liquid glue* by covering three parts of good glue, in small pieces, with eight parts of water, and, after it has stood for some hours, adding half a part of hydrochloric acid and three-fourths of a part of zinc sulphate, and exposing the whole for ten or twelve hours to a heat from 81.1° to 87.2° C. This does not gelatinize, and keeps well. For a *waterproof glue* add potassium dichromate to the solution of glue just before using, in the proportion of one part to fifty. (*A. J. P.*, xliii, 420.) *Chromatized gelatin*, obtained by the addition of one part of potassium dichromate to five parts of a solution (5 or 10 per cent.) of gelatin, forms an excellent cement for glass. The surfaces to be united, after being smeared with the cement, are placed upon each other and exposed to the sun. After a few hours the adhesion is perfect and almost invisible, and boiling water itself has no action on the cement. (*L. L.*, Nov. 11, 1876.) For other formulas for liquid glue, see *A. J. P.*, xliii, 421.

Glutaric Acid. *Acidum Glutaricum.* COOH.-CH_2.CH_2.COOH.—*Glutaric acid*, also called normal *pyro-tartaric acid*, forms colorless crystals, soluble in water and alcohol. It melts at 97° C. and boils above 290° under decomposition.

Wilenko (*D. M. W.*, 1908) found that glutaric acid diminished or caused a complete disappearance of the glycosuria caused by phloridzin. In a later communication (*Ther. Geg.*, 1909, 277) he reaches the conclusion that this action is due to an effect upon the kidneys, for he found acute parenchymatous nephritis and does not believe that the substance has any effect upon the metabolism. The *dose* which was employed ranged from one-half to one grain (0.03–0.065 Gm.) per kilo, body weight.

Glutoid Capsules.—Gelatin capsules which have been hardened by exposure to formaldehyde are recommended by Sahli in several grades, the weak capsule capable of withstanding the action of the gastric juices for from one and a half to seven hours, the strong for twelve hours. They appear to have great applicability for the purpose of conveying intestinal antiseptics, medicinal substances which are destroyed by the peptic secretions, and irritating drugs, through the stomach into the intestines. They have been used by Sahli (*D. A. K. M.*, lxi) for diagnostic purposes. By their means he asserts that he is able to determine the condition of the pancreatic secretion and the closure of the pancreatic duct, the varieties of jaundice, etc. (See also under *Gelatinum.*)

Glutol. *Glutoform.*—This is made by the action of the solution of formaldehyde upon gelatin. It is a hard, clear, transparent mass, which may be pulverized. It is claimed to be a non-irritating and non-toxic antiseptic, exerting its action only when in contact with living cells in consequence of the liberation of nascent formaldehyde, employed in the undiluted form as a dusting powder, etc.

Glycerinophosphoric Acid. *Acidum Glycerino-Phosphoricum. Glycerophosphoric Acid.* $H_2C_3H_5(OH)_2PO_4$.—This is an oily liquid whose salts have been commended as powerful nerve tonics in *neurasthenia* and allied conditions. Several of the salts are official, see *Calcii Glycerophosphas* and *Sodii Glycerophosphas* in Part I.

Glycosal. *Monosalicylic Glycerinester.* C_6H_4-OH.COO.$C_3H_5(OH)_2$.—This substance, originally prepared by E. Tauber, is a white crystalline powder, soluble (one per cent.) in cold water and freely in hot water, very soluble in alcohol, decomposed by alkalies and alkali carbonates, and also, it is said, by the intestinal juices with the separation of salicylic acid. Under the name of *antirheumol* a 20 per cent. solution of the glycerin esters of salicylic acid in glycerin and alcohol is claimed to have marked remedial effects in the treatment of *rheumatism*. A concentrated solution, 50 per cent. strength, is also marketed as "antirheumol concentrated." It is used externally with thorough friction. It is not to be confused with Glysal (see below).

Glycosal has been especially recommended as affording means of treating *rheumatism* by external application. Zeigan (*B. K. W.*, 1903) found that from 50 to 100 grammes of its twenty per cent. alcoholic solution, to which a little glycerin had been added, placed upon the rheumatic part and covered with waterproof wadding, was sufficient to produce in four or five hours strong sweating lasting from a half to two hours, and in from six to eight hours a notable elimination of salicylic acid with the urine with the relief of the local symptoms. Ratz, however, has been unable to secure absorption either by means of the alcoholic solution or yet by inunctions made with an indifferent fatty basis; although when ether, oil of turpentine, or chloroform was added in the proportion of fifteen per cent. to the ointment, a notable proportion of salicylic acid appears in the urine after the local application. R. Block (*Th. M.*, Sept., 1903) found that the best method of using glycosal is a twenty per cent. collodion, which he applied every two to four hours to swollen rheumatic joints with asserted most extraordinary results. He claimed that if no relief is afforded the inflammation may be positively considered not to be of rheumatic origin.

Glycosal is also used internally as an antirheumatic in *doses* of one hundred and fifty to one hundred and eighty grains (9.8–11.6 Gm.) a day, usually without the production of salicylism; eight to ten grains (0.5 to 0.65 Gm.) may be given every half to three hours until sweating is induced. The remedy is probably uncertain and feeble in its influence.

Glycotauro. *N. N. R.* 1924.—This is a proprietary preparation of bile salts freed from bile pigment and standardized to contain 50 per cent.

of the natural mixture of sodium glycocholate and sodium taurocholate. Each gramme represents about 10 cc. of fresh ox bile. (See *Extractum Fellis Bovis*, Part I.)

Glycozone.—A proprietary preparation claiming to possess antiseptic properties which has been found to consist essentially of 5 per cent. glyceric acid, 90 per cent. glycerin with a small proportion of water, and to contain no hydrogen or other peroxides or any ozones.

Glysal. *Spirosal. N. N. R.* 1924. *Mono-glycol Salicylate.* $C_6H_4OH.CO.O(CH_2.CH_2.OH)$.—It occurs as an almost colorless and odorless liquid, freely miscible with alcohol, and with eight parts of olive oil. It has been brought forward as a means of administering salicylic acid endermically. According to Schoenheim (*Med. Klin.*, 1907) it is more rapidly absorbed through the skin than the other preparations of salicylic acid intended for percutaneous absorption, and a number of clinicians have reported favorably upon its application in various forms of *rheumatism.* It has also been suggested for the treatment of *furunculosis* of the external auditory canal. It is applied either undiluted, or mixed with equal parts of alcohol, about a drachm at a dose, well rubbed into the skin, and then covered with impermeable dressing.

Gnaphalium. *Gnaphalium margaritaceum* L. (More correctly *Anaphalis margaritacea* (L.) Benth. and Hook.) *Pearl Everlasting. Cudweed. Life-everlasting. Pied de Chat, Immortelle,* Fr. *Katzenpfötchen, Immerschön,* G. (Fam. *Compositæ.*)—An indigenous herbaceous perennial, which with *G. obtusifolium* L. (*G. polycephalum* Michx.), or *sweet-scented life-everlasting,* is sometimes used in the form of tea in intestinal and pulmonary *catarrhs,* and, externally, in the way of fomentation, in *bruises,* but it probably possesses little medicinal virtue. In Europe different species of *Gnaphalium* are occasionally employed for similar purposes.

Gold.—The chief preparations of gold which have been employed in medicine are metallic gold in a finely divided state, the oxide (trioxide, incorrectly called *auric acid*), the chloride (trichloride), the iodide, the double gold and sodium chloride formerly official, the ammonium chloraurate (a compound of gold trichloride and ammonium chloride), and gold cyanide. Aqueous solutions of gold in the *colloidal* state have been prepared by Bredig by forming an electric arc under water with gold wires. The sparking between gold electrodes liberates finely divided gold which dissolves with bluish-red color. The addition of acids and certain salts coagulates this colloidal gold solution; the addition of gelatine prevents this coagulation. *Gold in powder* may be obtained by rubbing up gold leaf with ten or twelve times its weight of potassium sulphate until brilliant particles are no longer visible, and then dissolving away the sulphate with boiling water.

The soluble salts of gold are active disinfectants. Miquel found that 1 part in 4000 of the chloride would inhibit the growth of bacteria and according to Boer it is germicidal in strengths of from 1 part in 500 to 1 part in 8000 according to the species of bacteria. Behring asserts that the *gold and potassium cyanide* is an extraordinarily acting antibacterial, 1 part in 1,000,000 being sufficient to inhibit multiplication of these microorganisms.

Various preparations of gold have been highly lauded in the treatment of various forms of *tuberculosis* and *syphilis.* The cyanide and chloride were used many years ago in *scrofula.* Bruck and Glück (*M. M. W.*, 1913, p. 57) assert that the intravenous injection of the gold and potassium cyanide, through a systemic antiseptic influence, is a value in the treatment of *lupus.* They employed doses of from one-half to three-quarters of a grain (0.03 to 0.05 Gm.) two or three times a week. In a similar way it has also been used in *syphilis* and in *pulmonary tuberculosis.* Hauck (*M. M. W.*, 1913, p. 1824), however, reports a fatal case from the treatment which he attributed to gold poisoning.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels and otherwise acts as a corrosive poison. It is said that these preparations, in moderate doses, produce increased fulness and frequency of the pulse, and augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels, but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Under the name of *Crysolgan* (*Krysolgan*) the sodium salt of *amino-auro-thio-phenolcarbonic acid* was used by Lowy (*D. M. W.*, 1922, xlviii, 223) in *lupus* and various forms of local *tuberculosis.* The rapidity of recession of local lesions rivals the effects of the arsenicals in syphilis. He also noted marked improvement in cases of pulmonary and osseous *tuberculosis.* He administers intravenously 0.01 to 0.1 Gm. (⅙ to 1.5 grains) at weekly intervals.

Sanocrysin, a *sodium auric thiosulphate* which has been used by Molgard of Denmark, has acquired considerable notoriety and been attributed with an almost specific effect in *tuberculosis.* The drug is not free from danger and although it contains elements of hopefulness cannot be considered as of established value (see *J. A. M. A.*, 1925, lxxxiv, p. 287).

In 1889 Goubert asserted before the French Academy that *gold bromide,* administered in a weak solution, is more efficacious and durable in its action in *epilepsy* than are any of the other bromides, and is also better tolerated. This statement led Shtcherbak to study the effect of the gold bromide upon the motor area of the cerebral cortex, according to the method of Albertoni. He found that in the dose of from one-half to three grains per kilogramme of weight it so depressed the cortical motor centers that even the strongest electric stimulation failed to bring about any epileptic seizures. It is further asserted that the gold bromide never causes in man general depression, languor, emaciation, or other pronounced symptoms of bromism. The amount of bromine in the bromide, 55 per cent. by weight, would seem too small to make it probable that the bromine is the active ingredient of the salt. The *dose* of the bromide for the adult is from one-eighth to one-fifth grain (0.008–0.012 Gm.); for children, one-twentieth to one-tenth grain (0.003–0.006 Gm.). As a substitute for this preparation, E. Merck has proposed *gold* and *potassium bromide* (*Aurum-Kalium bromatum,* $AuBr_3.KBr + 2H_2O$), which has been tested by I. Jankura and Laufenauer (*Pest. Med. Chirurg. Presse,* 1892), and found to be a valuable anti-epileptic. It may be used hypodermically, by dissolving 2 parts of the salt in 100 parts of distilled water, and injecting of this eight minims (0.5 cc.) and increasing the dose to thirty-two minims (2 cc.). Solutions of gold pentabromide or pentachloride, recognized by their deep red color, are offered by several manufacturers under proprietary names, and advertised to produce remarkable effects in *anemia, diabetes,* and in various dyscrasias. *Solution of gold and arsenic bromide* is official in the National Formulary V under the name of *Liquor Auri et Arseni Bromidi,* the dose is given as three minims (0.2 cc.).

Ammonium chloraurate has been recommended by Bouchardat in *amenorrhea* and *dysmenorrhea* in debilitated subjects, in the *dose* of about the tenth of a grain (0.006 Gm.). A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Gold monocyanide (*aurous cyanide*) is a yellow insoluble powder, unstable in the sunlight. It has been used as an antitubercular.

The usual *dose* of either the chloride, cyanide, iodide or oxide of gold is from one-fifteenth to one-tenth of a grain (0.004–0.006 Gm.), most frequently given in pills. Gold cyanide has been found useful in the treatment of *syphilis* and *scrofula* by Pourché and is said to be less irritating than the double chloride.

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise until they are wanted for use, as they are liable to undergo decomposition when kept. They should be carefully secluded from the light.

Gold salts of various alkaloids have been prepared by Jowett. (*Tr. Chem. Soc.,* 1897.)

Gold and Sodium Chloride. *Auri et Sodii Chloridum U. S. IX. Chloride of Gold and Sodium.*—The U. S. P. formerly recognized, "A mixture of equal parts of anhydrous gold chloride [$AuCl_3$ = 303.58] and anhydrous sodium chloride, representing, when dried to constant weight in a desiccator over sulphuric acid, not less than 30 per cent. of metallic gold." *U. S. IX.*

Gold and sodium chloride may be prepared by dissolving gold in nitrohydrochloric acid, evaporating the solution to dryness, weighing and dissolving the dry mass in eight times its weight of distilled water. To this solution a weight of pure decrepitated common salt equalling that of the dry gold chloride is added, previously dissolved in four parts of water. The mixed solutions are then evaporated to dryness, being in the meantime constantly stirred with a glass rod. A process for making this salt from gold coin without requiring the preliminary purification necessary in the above process may be found in *Proc. A. Ph. A.,* 1882, p. 311. (See Kebler, *A. J. P.,* 1900, 325; and Averkief, *Chem. News,* 1903, 84.)

The pure crystallized salt, $AuCl_3NaCl.2H_2O$, is of a golden-yellow color, and is in the form of prismatic crystals. The mixture of the U. S. P. is described as "an orange-yellow powder, odorless, having a saline and metallic taste, and deliquescent when exposed to damp air. Gold and Sodium Chloride is very soluble in water; alcohol or ether dissolves the gold chloride leaving the sodium chloride. A fragment imparts a persistent, intensely yellow color to a non-luminous flame. An aqueous solution (1 in 100) shows a slightly acid reaction, and yields with silver nitrate T.S. a white precipitate insoluble in nitric acid but readily soluble in ammonia water. Hold a glass rod, moistened with ammonia water, close to a portion of Gold and Sodium Chloride; no white fumes appear (*free hydrochloric* acid). The filtrate from the precipitated gold in the following assay process, after acidulation with hydrochloric acid, is not affected by hydrogen sulphide T.S. (*metallic impurities*).

"Assay.—Dissolve about 0.5 Gm. of Gold and Sodium Chloride, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed in a stoppered flask, in 10 mils of distilled water in a porcelain dish. Render the solution alkaline by the addition of 10 mils of potassium hydroxide T.S., heat it for five minutes on a water bath, add 25 mils or an excess of solution of hydrogen dioxide and continue the heating for an hour on a water bath, or until the addition of a few drops of solution of hydrogen dioxide produces no further precipitation in the clear liquid. (During the heating on the water bath occasionally replace the liquid lost by evaporation by the addition of hot distilled water.) Wash the precipitate of metallic gold with distilled water slightly acidulated with hydrochloric acid, dry and ignite it. Its weight corresponds to not less than 30 per cent. of the weight of the dried Gold and Sodium Chloride taken." *U. S.*

This salt, like the other soluble salts of gold, was formerly used in the treatment of various chronic nervous diseases as *locomotor ataxia, neurasthenia,* etc. By many gynæcologists it is believed to have a specific direction to the genital organs, and it is used in *hysteria, ovarian irritation,* and even *chronic uterine inflammation.* It has also been commended in *syphilis, chronic rheumatism, diabetes mellitus,* and other chronic disorders affecting nutrition. Its greatest fame, however, was as the basis of the so-called "gold cure" treatment of the *alcoholic habit.* It would seem certain that no medication can suffice for moral reformation and any benefit from the drug must be by toning up the nervous system and bringing about a general increase of nutritive tone. *Dose,* one-twelfth to one-quarter of a grain (0.005–0.016 Gm.).

Gomabrea.—This is an exudation from a Chilian tree, which has been offered in large quantities in France as a substitute for gum arabic, and is said to be of practical value.

Gourd. *Bottle gourd. False calabash. East Indian calabash.*—The pulp of the root of the *Lagenaria leucantha* Rusby (*Lagenaria vulgaris* Ser., *Cucurbita Lagenaria* L.), a tender annual, probably native to tropical Africa and Asia (Fam. *Cucurbitaceæ*), was used by the natives of the Sandwich Islands in the treatment of *dropsy.* The fruit of certain varieties is edible but the pulp of the root possesses purgative powers.

Gratiola. *Gratiola officinalis* L. *Hedge-hyssop. Gratiole,* Fr. *Gnadenkraut, Gottesgnadenkraut,* G. (Fam. *Scrophulariaceæ.*)—This is a perennial herb, indigenous in the south of Europe, in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. The indigenous *G. virginiana* L. closely resembles the European plant and indeed was regarded by Michaux as identical with it. Both water and alcohol extract its active properties. F. G. Walz found in it two glucosides, *gratiolin* and *gratiosolin; gratioloic acid;* a fat and a brown resin. For chemistry, see *P. J.*, lxix, 295, and lxx, 385. Hedge-hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and has been used in Europe for the relief of *dropsy, jaundice, worms, chronic hepatic affections,* and *scrofula.* The *dose* of the powdered herb is from fifteen to thirty grains (1.0–2.0 Gm.); of the infusion (half an ounce to the pint of boiling water), half a fluidounce (15 cc.).

Ground Nuts. *Peanuts. Earth nuts. Goober-nuts.*—The fruit of *Arachis hypogœa* L., a leguminous, annual plant, probably native to Brazil and abundantly cultivated in our Southern States, China, etc. Although this fruit is universally known as a nut it bears neither botanical, chemical nor nutritional relations to the true nuts.

A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate after flowering, until the young fruit is completely buried under the soil in the progress of their growth. The kernels or seeds contain about 45 per cent. of a fixed oil. (See *Oleum Arachis*, Part I.)

Guaco.—Although the guacos of South America seem to be entirely distinct drugs they appear to be indiscriminately used by the natives for the cure of the *bites of poisonous serpents.* The most important of these belong to the genus *Aristolochia.* Guaco is also used in South America as a febrifuge, anthelmintic, antirheumatic and antisyphilitic. Some years ago it attracted considerable attention on the continent of Europe on account of its alleged power in *epidemic cholera* and *chronic diarrhea.* The *Aristolochia cymbifera* Mart. and Zucc. has been the subject of a careful study by L. Butte. (*Annales de la Policlin. de Paris*, Sept., 1890.) The root of this plant as it occurs in commerce is cylindrical, from three to four centimeters in diameter, much broken up into long rootlets, yellowish, with a strong odor, especially in the bark. The plant itself is a vine, growing in great abundance in the province of Tabasco in Mexico. Butte was not able to find in it either an alkaloid or a glucoside. In the physiological experiments made with the aqueous extract it was found that massive doses produced cries and excitement, followed after a time by sleep, with muscular relaxation and symptoms of gastro-intestinal irritation. There was also depression of the nerve centers, both sensory and motor. If the dose were sufficient death was produced by an arrest of the respiration. The heart continued to beat after the cessation of respiration; nevertheless there was depression of the arterial pressure, apparently due to the action of the drug upon the heart. After death marked signs of irritation of the gastro-intestinal tract and kidneys were found. Butte believes that guaco has valuable therapeutic properties in the treatment of skin affections, especially *eczema* and *pruriginous maladies,* in which he used it both locally and internally. He gives the *dose* of the aqueous extract of guaco as three grains (0.2 Gm.) three times a day. In the external application the following formula was used. Guaco (bruised), 30 parts; sodium bicarbonate, 5 parts; water, 1000 parts; boil for a quarter of an hour, allow to macerate one hour, decant, and use the liquid as a lotion. Another form of guaco, sometimes known as *guaco de San Cristobal,* is derived from species of *Aristolochia* (Fam. *Aristolochaceæ*). This is probably derived from *Aristolochia fragrantissima* Ruiz., *A. grandiflora* Sw., and *A. pentandra* Jacq. Apparently the *Comocladia integrifolia* Jacq. of the *Anacardiaceæ* also furnishes a variety of guaco.

Species of the genus *Mikania* (*Willugbœya*), composite plants related to the Eupatoriums, are also used in Brazil under the name of Guaco against snake and scorpion bites. The species most frequently employed are *M. amara* Willd. and *M. Gauco* H. B. K.

M. amara is described as having twining stems, with round, sulcate, and hairy branches; ovate subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above and hairy beneath, and flowers in opposite axillary corymbs. The plant is a native of tropical America, and has been introduced into the West Indian Islands from the continent. The leaves are the part used. The result of a long and close investigation into the natural history of guaco by Guibourt is, that the guaco from this source, instead of possessing, as has been asserted, a strong, penetrating, and nauseous odor, is in fact inodorous, and destitute of all active properties, and that the strongly aromatic plants which have been employed under the name of guaco all belong to the genus *Aristolochia,* especially *A. cymbifera* Mart. and Zucc., growing in Brazil, after this *A. maxima* (DC.), and in less degree *A. maxima* Jacq. (*A. geminiflora* H. B. K.). (*J. P. C.*, 1867, 99.)

Guaiacol Compounds and Derivatives.—A very large number of these compounds have been produced by pharmaceutical chemists and put upon the market as substitutes for and improvements on ordinary guaiacol. The advantages claimed for these compounds are lower toxicity; especially lack of irritant effects on the mucous membrane of the stomach. In regard to their manufacture we refer the reader to elaborate papers by F. G. Ehlert (*Ph. Rev.*, 1901 and 1902).

Guaiacol Albuminate. Histosan.—According to Huhs (*Ther. Geg.*, 1907, 313), while of service it is not superior to other creosote preparations. The *dose* is eight to twelve grains (0.5–0.75 Gm.) three times a day.

Guacamphol. Guaiacol Camphorate. $C_8H_{14}.(COOC_6H_4O.CH_3)_2$.—This *camphoric ester of guaiacol* is a white, tasteless, insoluble powder, which is asserted to be broken up in the intestines into camphoric acid and guaiacol. It has been especially recommended as a remedy of great value in the treatment of the *night sweats of phthisis.* In some cases it is necessary to be administered for one or even two weeks for the desired effect. *Dose,* three to fifteen grains (0.2–1.0 Gm.) exhibited two hours before bed time.

Guaiacol Acetate. Eucol. Eucolo. Guaiacol Ester of Acetic Acid. $C_6H_4\left\langle\begin{matrix}OCH_3\\OCH_3CO\end{matrix}\right.$.—This product forms a colorless fluid with a specific gravity 1.138, and boiling at 238° C. with partial decomposition. It can be mixed in any proportion with ether or alcohol and may be dissolved to the extent of 20 per cent. in olive oil. It is used for the same purposes as guaiacol.

Guaiacol Benzoate. Benzosol, N. N. R. 1924. $C_6H_5COO.C_6H_4.OCH_3$.—This occurs as colorless crystals with a faint aromatic odor almost insoluble in water. It is slowly decomposed in the intestines and appears to exert the characteristic effects of its two constituents. Benzosol was highly commended by Walzer and Hughes (*D. M.*

W., 1891) as a substitute for creosote in *phthisis*, and has been used to a considerable extent by clinicians as an intestinal antiseptic in *intestinal indigestion, diarrhea*, and other conditions. It has also been used successfully in *cystitis*, and is affirmed by Piatokowski, J. Blake White, and others to be valuable in the treatment of *diabetes*. *Dose*, five to ten grains (0.3–0.6 Gm.) several times a day.

Guaiacol Benzyl Ester. Pyrocain. Brenzcain. $OCH_3.C_6H_4.OCH_2.C_6H_5$.—This is in colorless crystals, soluble in ether and melting at 62° C. It possesses the general therapeutic properties of guaiacol, but is less caustic. It is not to be confused with Benzosol (guaiacol benzoate).

Guaiacol Cinnamate or *Styracol*, $C_6H_5CH{:}CH.COO(C_6H_4OCH_3)$, the cinnamic acid ester of guaiacol, occurs in white, odorless, tasteless, stable needles, almost insoluble in water, readily soluble in alcohol, chloroform, acetone and benzene. They fuse at 130° C. It is said when taken internally to be broken up in the intestines into cinnamic acid and guaiacol and to be useful not only in *phthisis* but in various chronic *gastro-intestinal* and *genito-urinary catarrhs*. *Dose*, fifteen grains (1 Gm.), three or four times a day.

Guaiacol Ethyl, $C_6H_4OC_2H_5OH$, *Pyrocatechin Monoethyl Ether. Guethol. Thanatol.*—This is an oily liquid of an agreeable aromatic odor, soluble in water, which was brought forward as a remedy in *tuberculosis*, with the statement that it acts upon the human system like guaiacol, but more quickly and energetically. The researches of De Buck (*Belg. Méd.*, 1897) indicate, however, that it is not more effective than is guaiacol in tubercular diseases. It is affirmed, however, to be a pronounced analgesic, which when applied to the skin by means of a brush is rapidly absorbed, and in cases of *neuralgia* or *neuritis* produces great relief. It may also be used subcutaneously in 10 per cent. emulsions with sterilized glycerin, and has been so applied; the glycerin solution has also been used in *cystitis*.

Guaiacol Methylglycolate. Monotal. Methylglycolic Acid Ester of Guaiacol. $CH_2(OCH_3)COO(C_6H_4OCH_3)$.—This is a colorless, oily liquid, slightly aromatic, almost insoluble in water, soluble in alcohol and immiscible solvents. It is readily absorbed through the skin and is employed not only for its local anesthetic properties in various painful conditions, but to obtain the systemic effects of guaiacol through endermic administration. It is said to produce the effects of guaiacol without its toxic properties. Externally applied in *doses* of one-half to one fluidrachm (2–4 cc.).

Guaiacol Phosphate. Phosphoric Guaiacol-ether. Biogaicol. $(C_6H_4O.CH_3O)_3PO$.—A white, crystalline powder has been shown by A. Gilbert (*S. M.*, 1897) to be split up in the intestines, with the liberation of its constitutents, and to afford, therefore, a method of administering guaiacol, over which it has the advantage of being innocuous to the mucous membrane of the stomach. It would appear, however, much less active and much more uncertain in its influence than is guaiacol. *Dose*, one to three grains (0.06–0.2 Gm.).

Guaiacol Phosphite. Phoso-Guaiacol. $P(OC_6H_4OCH_3)_3$. *Phospho-guaiacol. Guaiacophosphal.*—*Phosphite of Guaiacyl-ether* is a white, crystalline powder, possessing a sharp taste and indifferent odor. It is soluble in water, dissolves very freely in alcohol, ether, chloroform, acetone, benzene, toluol, and the fatty oils, but it is sparingly soluble in oil of turpentine and in glycerin. Melting point 77.5° C. It contains 92.25 per cent. of guaiacol, and was introduced in 1897 by Ballard. (*Rép. de Pharm.*, 1897.) *Dose*, three to fifteen grains (0.2–1.0 Gm.).

Guaiacol Salol. Guaiacol Salicylate. $C_6H_4OHCOO(C_6H_4OCH_3)$.—A compound closely related to phenyl salicylate (salol) which occurs in small odorless, tasteless, colorless crystals, readily soluble in alcohol, ether, chloroform or benzene, melting at 65° C. It is said to be split up into its constituents in the intestines and has been used in *phthisis* and as an *intestinal antiseptic*. *Dose*, ten to fifteen grains (0.65–1.0 Gm.).

Guaiacol Succinate. $(C_6H_4OCH_3)_2C_4H_4O_4$.—This drug occurs in fine, silky, white crystals insoluble in water, slightly so in alcohol and ether, very soluble in chloroform or acetone, and melting at 136° C. It is said to act medicinally like guaiacol.

Guaiacol Valerate. Geosote. $C_6H_4OCH_3O.COC_4H_9$.—This occurs as a pale yellow, oily, mobile liquid, insoluble in water, freely soluble in alcohol, ether, and benzene. Sp. gr. 1.038, boiling point variously given from 240° to 260° C. Geosote is used in *phthisis* and as a gastro-intestinal antiseptic in fermentative *dyspepsia* and *diarrhea*. *Dose*, five to ten grains (0.32–0.65 Gm.).

Guaiacose.—This is stated to be a combination of *calcium guaicol-sulphonate* with somatose which is a partially digested protein. Guaiacose occurs as a dark brown fluid with a not unpleasant taste and miscible with water. The dose recommended is about 1 teaspoonful 3 or 4 times a day.

Guaiacyl. Gajacyl. Calcium Ortho-guaiacol Sulphonate. $(C_6H_3(OH).(OCH_3)SO_3)_2.Ca$.—This is a powder of a bluish-gray color, soluble in water and in alcohol. The aqueous five per cent. solution has a violet-red color and may be used hypodermically in quantities of eight to twenty minims (0.5–1.3 cc.). *Guaiacyl* has also been used as a local anesthetic in 5 to 10 per cent. solution.

Guaiaform. Geoform. Methylenediguaiacol. Pulmoform.—The drug is a tasteless yellow powder, odorless at first but acquiring a vanilla-like odor, soluble in alcohol or ether but insoluble in water. It is affirmed to contain 95.38 per cent. of guaiacol and to be non-irritating and non-toxic. *Dose*, five to fifteen grains (0.3–1.0 Gm.).

Guaiaquin. Quinine Guaiacol Bisulphonate. $C_6H_4O_2CH_3HSO_3\ \ C_{20}H_{24}N_2O_2$.—This substance occurs as a yellowish crystalline bitter powder, very soluble in water, alcohol and diluted acids. It represents about 45 per cent. of quinine and 34 per cent. of guaiacol. It has been used to some extent in internal medicine as a tonic, but especially as an antiperiodic in various *malarial diseases* with asserted good results. It is stated that the sterilized 10 per cent. solution may be given hypodermically with the production of little pain. This solution has also been used locally with alleged good results in *gonorrhea* and other infected conditions. *Dose*, three to ten grains (0.2–0.65 Gm.); sixty grains (3.9 Gm.) may be given in a day.

Guaiasanol. Gujasanol. Diethyl-glycocollguaiacol Hydrochloride.

$$C_6H_4\begin{matrix}\diagup OCH_3\\ \diagdown O.CO.CH_2N.(C_2H_5)_2.HCl\end{matrix}$$

This substance occurs in very soluble white prisms fusing at 184° C., emitting an odor faintly suggestive of guaiacol and possessing an acrid taste. It was first produced by Einhorn and Hutz (*J. P. C.*, 1903, 174) through the union of aceticomonochlorguaiacol and diethylamine. In the presence of alkalies it breaks up, liberating guaiacol, which has been found in the urine of animals to which it had been given. Guaiasanol was introduced as a substitute for guaiacol, especially in the treatment of *pulmonary catarrhs.* Rahn (*M. M. W.*, 1905, p. 783) has also found the injection of a 2 to 4 per cent. solution a valuable treatment for *seat worms.* It has been given in *doses* of forty-five to one hundred and eighty-five grains (3–12 Gm.) daily.

Guajamar. Guaiamar. Guaiacolglyceryl Ester.—This is a white crystalline powder,  $C_6H_4\left\langle\begin{matrix}OCH_3\\OC_3H_7O_2\end{matrix}\right.$, which possesses a bitter aromatic taste, melts at 75° C. and dissolves in alcohol, ether, glycerin or 20 parts of water at the ordinary temperature. According to G. Buttler, it splits up in the intestines into guaiacol and glycerin and affords an excellent method of intestinal antisepsis in *typhoid fever, diarrhea,* etc. Great relief has been obtained in *acute* and *articular rheumatism* by the local application of the remedy in the form of an ointment consisting of two parts of guajamar and one of lanolin. *Dose,* three to fifteen grains (0.2–1.0 Gm.).

Guano. *Bird-manure.*—A fertilizing excrement formerly found on many small islands in the southern ocean on the western coast of Africa and also near the Peruvian Coast of South America, but exhausted many years ago for agricultural purposes. These islands were the resorts of large flocks of sea birds and formerly the beds of deposited excrement were sometimes 50 or 60 feet in depth. It constituted an excellent manure and was used for upward of a century for that purpose. It consisted of phosphates together with much ammonium urate and ammonium oxalate, and some peculiar nitrogenous bases. At present small amounts are obtained from the Peruvian islands. Guano is a powerful local irritant, and was sometimes employed as an external stimulating application. For further information see 16th ed., *U. S. D.*

Gum Cebil.—This gum is a product of the Brazilian leguminous tree, *Piptademia Cebil* Griseb. It occurs in reddish-yellow tears, or in dark-colored angular masses, and forms a reddish-yellow, odorless, viscous mucilage of acid reaction. It is said to contain 80.78 per cent. of arabin.

Gum, Cedar.—This, the product from *Cedrela Toona* Roxb. (*Toona ciliata* Roem.), or *Red Cedar,* a tree native of the Himalayas but growing in Queensland (Fam. *Meliaceæ*), is a very pale yellow or brownish gum, occurring in tears about 2.5 cm. long, having an astringent taste, swelling and, finally, almost dissolving in water. It contains about 68 per cent. of arabin, and 6 per cent. of metarabin, but no resin. (*P. J.*, vol. xx, 1890.)

Gum, Indian.—Under the name of *Gummi Indicum* the Br. recognizes the gummy exudation from the wood of *Anogeissus latifolia* Wallich. (Fam. *Combretaceæ*), a tree native to India and Ceylon. (See Part I.) The forests of India produce large quantities of other gums, a number of which have found their way in commerce and are used to a considerable extent as substitutes for gum arabic and gum tragacanth. Several of these are known colloquially as "Indian Gum." Among them that yielded by *Prosopis spicigera* L. (Fam. *Leguminosæ*) occurs in small, angular, yellowish fragments, or sometimes in large ovoid tears 5 cm. long, of an amber color, frosted externally with fissures. It forms with water a dark-colored tasteless mucilage and resembles in its behavior to reagents the *Mesquite gum.* The gum of *Feronia Limonia* Swingle (Fam. *Rutaceæ*) is in small, irregular tears varying from reddish-brown to pale yellow and forms a thick, tasteless, colorless mucilage which resembles gum arabic, but is precipitated by neutralized lead acetate and gelatinized by ferric chloride, although unaffected by borax. (See also *Gum Sterculia* and *Bassora.*)

Gum Mango.—This gum, which is obtained from the mango tree, *Mangifera indica* L. (Fam. *Anacardiaceæ*), occurs in the Indian bazaars in amber-colored or reddish-yellow lumps, almost transparent, with a brilliant conchoidal fracture, 39.4 per cent. of which is soluble in water. (See *J. P. C.*, xix, 584.)

Gum Mesquite. *Mesquite Gum. Mezquite Gum.*—This is the product of *Prosopis juliflora* DC., and perhaps other species of the same genus. Mesquite is a small, thorny, acacia-like tree or shrub belonging to the Fam. *Leguminosæ,* and growing in New Mexico, Texas, and other neighboring regions, where it covers vast extents of country. The fruit is a long, compressed pod, filled with a sweet pulp, which is said to contain 30 per cent. of grape sugar, and to be used by the Indians as a food. A gum exudes from the stem and branches. It occurs in irregular, roundish pieces, of various sizes and usually of a dark amber-brown color, though sometimes, especially when gathered from young trees, it is nearly colorless. Procter found it to resemble gum arabic in its solubilities, but to differ essentially in not being precipitated by lead subacetate, and in its strong solution not being coagulated by borax. (*A. J. P.*, xxvii, 224.)

The saccharine pods of *Prosopis odorata* Torr. and Frem. (*P. pubescens* Benth.) are largely employed as food by the Indians, and those of all the species form valuable fodder for cattle.

Gum Sassa. *Sassa Gum.*—This name has been applied by Guibourt to a gum, occasionally brought into commerce from the East. It is produced by a tree growing in Abyssinia, *Albizzia fastigiata* Oliv. (Fam. *Leguminosæ*). According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish color and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither, like tragacanth, forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

Gum Sonora. *Sonora Gum.*—According to Krewson, the exudation from *Covillea tridentata* (DC.) Vaill. (*Larrea mexicana* Moric.) contains 17.27 per cent. of resin, and 11.71 per cent. of mucilage and allied substances. (For details, see *P. J.*, xvi, 128; also *A. J. P.*, May, 1898.) This plant is known in Southwestern United States and Mexico as *Creosote bush,* because of the odor of the oleoresin which covers the herbage.

Gum Sterculia. *Sterculia Gum. Indian Tragacanth. Indian Gum. Karaya Gum.*—A number of trees belonging to the genus *Sterculia* in India—particularly *Sterculia urens* Roxb., and *Cochlospermum gossypium* DC.—Africa, and Australia yield gums in considerable quantity, most of which resemble in their appearance tragacanth, some of which have remarkable adhesive properties and in some of which the adhesive power is lacking but the swelling power when moistened with water is enormous. These gums have been much used of recent years, frequently under the unqualified name of tragacanth. They are employed frequently as fillers in the manufacture of ice cream and even desserts where vegetable gums are found to be of service in preventing the product from losing its form as it melts. The difference between the sterculia gums and true tragacanth can be readily proved by a distillation test with water and the determination of the acidity which is due to acetic acid. (See *A. J. P.*, Jan., 1900; 1912, pp. 155 and 393; *Drug. Circ.*, 1909, p. 116; *J. A. Ph. A.*, 1917, vi, 88.)

Gutta-Percha. *N. F. IV. Gutta Pertscha. Gutta Gettania. Gutta Taban. Getah Pertscha. Getah Taban. Guetah* or *Gueutta-pertcha* Malay (from *gueutta*, gum and *pertcha*, rags or scraps). *Gummi plasticum.*—This is a hydrocarbon defined by the N. F. as "the purified, coagulated, milky exudate of various trees of the genus *Palaquium* Blanco (Fam. *Sapotaceæ*)." Nevertheless, it is also obtained from trees belonging to the genus *Payena* (Fam. *Sapotaceæ*). These plants are all tropical trees, which are characterized by possessing rows of latex cells in the cortex, pith and leaves. Their leaves are alternate, evergreen and leathery in texture and they possess large, perfect axillary clusters of flowers and berry fruits. It is somewhat like India rubber, but less elastic, so that when changed in form by mechanical force it preserves its new shape. At a temperature of boiling water it becomes highly plastic and, on cooling, of preserves the shapes in which it has been molded, while India rubber, treated by heat, preserves its elasticity until the temperature becomes excessive, when it changes in its physical and chemical properties. Perhaps the most important difference between the two substances is in their reaction with sulphur, rubber readily vulcanizing, gutta-percha being practically incapable of so doing.

The plants which are capable of yielding gutta-percha are quite numerous, but those yielding the commercial substance inhabit the limited region of South America between the third degree of south and the fifth degree of north latitude, and the limited portion of Asia between longitude 102° and 112°. It is probable that other equatorial or sub-equatorial regions do, however, produce gutta-percha.

Formerly the most important of the gutta-percha yielding trees was *Palaquium Gutta* Burck (Fam. *Sapotaceæ*). This furnished the article known commercially as *Gutta Taban* or *Getah Taban.* Most of the gutta-percha of commerce is now obtained from *P. oblongifolium* Burck; *P. borneense* Burck; *P. Treubii* Burck and *Payena Leerii* Benth. et Hook. All of these are natives of Malaya. At the present time some of these species are being cultivated, viz., *Palaquium Gutta* and *Palaquium oblongifolium* are being cultivated in sumatra—the latter being said to yield the best of all the gutta-perchas, and it is stated that *P. pustulatum* is cultivated in Ceylon and *Payena Leerii* in its native Sumatra. At the present time most of the guatta-percha is obtained from Sumatra.

Gutta-percha is also obtained in considerable quantities in the Philippine Islands, whence it is sent to Singapore. In obtaining gutta-percha, after the tree has been cut down, incisions are made through the bark into the latex, and the milk, after having been collected in gourds, is coagulated by heat, the resulting masses washed by kneading with water, increased in weight by additions of wood, dirt, pebbles, etc., and finally sent into trade worked into masses with a fair exterior.

It has been proven by the researches of Jungfleisch that the leaves of the gutta-percha trees contain, even after drying, nine per cent. of gutta-percha, as extracted by toluene. Hitherto the leaves have been simply lost in the forest. It is further stated that the year's product of leaves of the thirty year old tree will yield as much gutta-percha as does the tree when cut down, and efforts are being made to induce the Malays to collect the leaves instead of destroying the trees. Patents have been taken out for at least four different processes, in which carbon disulphide, toluene, rosin oil and light petroleum are used as solvents.

In Singapore the gutta-perchas of various sources are mixed, and three commercial articles are sold—viz., (1) first quality, (2) medium quality, (3) white gutta-percha.

Small quantities of commercial gutta-percha may be freed from impurities and obtained perfectly white by dissolving one part of gutta-percha in twenty of boiling benzene, shaking the solution frequently with calcium sulphate, which upon standing two or three days carries down with it the coloring matter, then decanting the clear liquid, and adding it, in small portions at a time, to alcohol, agitating continually. The deposited gutta-percha is then dried by exposure to the air.

It was described as "in masses, sticks or sheets of irregular size and shape, tough, yellowish-white in color and usually with reddish, marbling streaks. Insoluble in water; partly soluble in chloroform, carbon disulphide, petroleum benzin, or oil of turpentine, leaving not more than 10 per cent. of undissolved residue. Slightly elastic at ordinary temperatures, becoming pliable at from 25° to 30° C. It gradually softens on further heating, becoming quite plastic at 60° C. One Gm. of Gutta Percha when boiled for one hour with 20 cc. of dehydrated alcohol in a flask, connected with a reflex condenser, leaves not less than 0.5 Gm. of undissolved residue. When exposed to air and sunlight, Gutta Percha absorbs oxygen and becomes brittle. Gutta Percha yields not more than 5 per cent. of ash." *N. F.* Its sp. gr. is 0.9791. (Soubeiran.) At about 49° C. it becomes softer and more flexible, but is still elastic, resisting, and tenacious. At from 66° to 71° C. it is soft, very plastic, and capable of being welded and molded into any form. It can be softened either by means of hot water or by dry heat. On cooling, it reassumes its former state, and retains any form which may have been given to it. In the softened state it is readily cut with a knife, though with some difficulty when cold. Exposed to a heat of 166° C., it loses a portion of water, and on hardening becomes translucent and gray; but it recovers its original characters if immersed in water. Subjected to destructive distillation, it yields volatile products resembling closely the volatile oil obtained from caoutchouc by the same process. Heated in an open vessel, it melts, foams up, and takes fire, burning with a brilliant flame and much smoke. A portion thus melted retains the state of a viscid fluid on cooling. Gutta-percha is a non-conductor of electricity. It is insoluble in water, alcohol, alkaline solutions, and the weak acids. Ether and the volatile oils soften it in the cold, and imperfectly dissolve it with the aid of heat. It is partly soluble in carbon disulphide, chloroform, petroleum benzin, and oil of turpentine, leaving not more than 10 per cent. of undissolved residue. It does not yield more than 3 per cent. of ash.

Its composition is closely analogous to, if not identical with, that of caoutchouc. According to Bamhauer, pure gutta-percha, as it issues from the tree, is a hydrocarbon, with the formula $(C_{10}H_{16})_2$, which he calls *gutta*, and by the oxidation of which, in various degrees, the different bodies constituting gutta-percha are produced. This hydrocarbon can be separated by treating gutta-percha with diluted hydrochloric acid, and boiling the residue with ether, which deposits the gutta on cooling, but the ethereal treatment must be frequently repeated to obtain it quite pure. (*J. Pr. Chem.*, lxxviii, 279.) Arpe considers gutta-percha as a mixture of six different resins which may have been formed from a hydrocarbon, $C_{10}H_{16}$. (See *Chem. Gaz.*, ix, 471.) Oudemans (*Jahresb.*, 1859, 517) finds two resinous products in gutta-percha: *fluavil*, fusing at 42° C. with the formula $C_{20}H_{32}O$, and soluble in cold alcohol, and *albane*, fusing at 140° C., with the formula $(C_{10}H_{16}O)_2$, and soluble in chloroform, carbon disulphide, and ether, from which last it crystallizes out on cooling. Payen has shown that three proximate principles exist in the natural gutta-percha—viz., *gutta* (insoluble in cold alcohol and in boiling alcohol), 78 to 82 per cent.; *fluavile* (insoluble in cold alcohol), 4 to 6 per cent.; *albane* (soluble in boiling alcohol), 14 to 16 per cent. Gutta-percha resists putrefaction strongly; but in certain situations, as when employed to protect underground telegraph wires passing near the roots of the oak, it has been observed to undergo speedy decomposition, in consequence, it is supposed, of the action of fungi. (*P. J.*, xvii, 193.)

Gutta-percha is employed very largely in the arts for various purposes, especially as an insulating material. In medicine it is used simply for mechanical purposes, as in the formation of splints and the manufacture of surgical instruments. For details of its use the reader is referred to works on surgery.

Gymnema. *Gymnema silvestre* (Willd.) R. Br.—This is a woody climber, belonging to the *Asclepiadaceæ*, which grows in Australia, India and also in Africa. The root has for a long time been employed by the natives as a remedy in *snake bite*, and it is affirmed by T. Dyer (*Nature*, 1887) that directly after the eating of one or two leaves it is impossible to taste sugar, though other tastes are not obscured; thus, pungency alone is detected in gingerbread, and a sweet orange tastes like a lime. The active principle is *gymnemic acid*, $C_{32}H_{55}O_{12}$ (see *J. Chem. S.*, 1904, lxxxv, 624), and has been used with considerable success as a remedy for *parageusia* and *hallucinations of taste*. The 1 per cent. aqueous solution is to be applied with a brush to the inside of the mouth, or a hot infusion (15 per cent.) of the crude drug may be used. (See *Th. M.*, ix.)

Gymnocladus. *Gymnocladus dioica* (L.) Koch. (*G. Canadensis* Lam.) *Kentucky Coffee-tree. Kentucky Mahogany.* (Fam. *Leguminosæ.*)—A tall tree with bipinnate leaves, terminal panicles of greenish-white flowers, growing in the woods from New York southward and west as far as Oklahoma. The fruit is an oblong, flattened pod, persisting through the winter; it contains several seeds in a fleshy pulp. The seeds are flattish and about 1 cm. in diameter. According to Bartholow, the aqueous extract of the seeds is toxic. (*Am. Drug.*, April, 1886.) Mell (*A. J. P.*, 1887, 230) obtained from them about 10 per cent. of fixed oil which is yellowish, saponifiable, and of sp. gr. 0.919, tannin, and a small quantity of glucoside. This latter had a peculiar odor and an acid burning taste. James H. Martin (*A. J. P.*, 1892, 558) obtained a yellow, saponifiable oil from the bean and the bark and a glucoside from the pulp. Sayre and Watson found in the seeds saponin and a toxalbumin similar to if not identical with that of ricin, the poisonous principle of castor bean. (*J. A. Ph. A.*, 1917, vi, 601.) They state that while the raw seeds are poisonous after roasting they may be eaten with impunity. In Colonial times they were used, west of the Alleghanies, as a substitute for coffee.

Gynoval. *Ferminal.*—Gynoval is the iso-valeric ester of iso-borneol, $(CH_3)_2CH.CH_2.COOC_{10}H_{17}$. It occurs as a colorless, neutral fluid with a peculiar aromatic odor and a slightly oily taste, very sparingly soluble in water, but readily soluble in alcohol and ether. Gynoval is asserted to have the advantage over other preparations of valeric acid that it does not irritate the stomach. It is employed in *hysteria* and the various functional neuroses for which valerian is commonly recommended. It is administered generally in capsules containing four minims (0.25 cc.) of which one or two may be given at a *dose*.

Halozone. *Para-sulphon-dichloramido-benzoic acid.* $C_6H_4(SO_2NCl_2)COOH$.—This compound which is formed as a by-product in the manufacture of glusidum occurs as a white crystalline powder with a pronounced chlorinous odor, sparingly soluble in water but forming soluble salts with the alkalies. Its melting point is 213° C.

Halozone was introduced by Dakin and Dunham as a means of purifying water by chlorination. (*B. M. J.*, Jan. 29, 1916 and May 26, 1917.) They state that 1 part in 300,000 will sterilize ordinary water in about 30 minutes without destroying its palatability and that in the amounts required it is completely innocuous. These conclusions have been confirmed by Fantus (*J. A. Ph. A.*, 1918, vii, 1034 and *J. Inf. D.*, 1919, xxiv, 200) who fed to kittens and rabbits doses which would be equivalent to 7 Gm. daily for a man (enough to disinfect more than 400 gallons of water), for 4 months without observable effect. He also found that tablets of halozone showed no change in the proportion of available chlorine after 4 months, while similar tablets of chlorinated lime had lost 30 per cent. of their available chlorine in the same period. While for disinfecting large masses of water, as in municipal plants, the chlorinated lime is cheaper and equally efficient he concludes that halozone is of great practical value because of the practicability of tablet form. While the slowness of its action is a drawback Fantus finds that this may be greatly accelerated by the simultaneous use of small amounts of citric or other organic acid.

Because of the greater solubility of its salts the tablets of halozone usually contain sodium bicarbonate or sodium borate, sodium chloride is also added to give bulk.

Hectine. *Sodium-benzo-sulpho-paramino-phenyl-arsenate.*  $C_6H_5SO_2NHC_6H_4N\begin{smallmatrix}/O\\ -OH\\ \backslash ONa\end{smallmatrix}$.—It occurs as colorless needles, freely soluble in water, the solution not being decomposed by boiling. It has been brought forward as an organic arsenical, especially for the treatment of *syphilis* and *filariasis* and a number of practitioners have used it with good effects. Whether or not it will give rise to optic neuritis, as does atoxyl, is uncertain, but Ballet and Hirschmann (*Press. Med.*, 1911) have reported temporary disturbance of vision from its use. The *dose* recommended is from one and one-half to three grains (0.096–0.2 Gm.) daily, injected deeply into the muscle; by mouth, one grain (0.065 Gm.) several times a day. This treatment is kept up for two weeks and then discontinued for two weeks and this method is repeated as long as necessary.

Hedeoma. *Pennyroyal. American or Mock Pennyroyal. Squawmint. Mosquito Plant. Herbe de Pouliot Américaine,* Fr. *Amerikanischer Polei,* G.—The U. S. VIII recognized "The dried leaves and flowering tops of *Hedeoma pulegioides* (Linné) Persoon (Fam. *Labiatæ*)." *U. S. VIII.*

This plant is entirely distinct from *Mentha Pulegium* or European pennyroyal. It is probable that various other species of the genus are used in the localities in which they grow. Thus, *H. piperita* Bentham is said to be used in Mexico as a substitute for peppermint, and *H. thymoides* Gray, in Texas as an aromatic diaphoretic.

Hedeoma pulegioides (L.) Pers. [*Cunila pulegioides* L.; *Melissa pulegioides* L.] is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent, quadrangular stem, which sends off numerous slender erect branches. The plant is common in the Eastern and Middle Western United States, preferring dry grounds. Hedeoma was officially described as "branchlets quadrangular, with numerous spreading hairs; leaves opposite, short-petioled, oblong, 15 to 35 Mm. long, thin, obtuse, obscurely serrate, glandular-hairy beneath; flowers in axillary fascicles, with a tubular-ovoid, bilabiate and 5-toothed calyx, and a pale blue, spotted, bilabiate corolla containing two sterile and two fertile, exserted stamens; odor strong, somewhat mint-like; taste aromatic and pungent." *U. S. VIII.* The activity of hedeoma depends upon a volatile oil. The oil of hedeoma (*Oleum Hedeomæ, U. S. VIII, Oil of Pennyroyal*), is "A pale yellow, limpid liquid, having a characteristic, pungent, mint-like odor and taste. Specific gravity: 0.920 to 0.935 at 25° C. It should form a clear solution with 2 volumes or more of 70 per cent. alcohol. It is dextrogyrate, the angle of rotation varying from about $+ 18°$ to $+ 22°$ in a 100 Mm. tube, at a temperature of 25° C." *U. S. VIII.* Its chemical composition was investigated by E. Kremers (*A. J. P.*, 1887, p. 535) and F. W. Franz (*A. J. P.*, 1888, p. 161). Each of them found a body of the composition $C_{10}H_{18}O$, boiling at 217° to 218° C. (constituting, according to Franz, about 33 per cent. of the oil). For this the name *hedeomol* was proposed. Franz also found a body of the composition $C_{10}H_{17}O$, boiling at 220° to 225° C., and constituting 12 per cent. of the oil; likewise a body of the composition $C_6H_{12}O$, boiling at 165° to 170° C., and constituting about 0.7 per cent. of the oil. Both investigators found formic and acetic acids, and Kremers considers *isoheptoic acid* also to be present. Beckmann and Pleissner (*Ann. Ch. Ph.*, cclxii, p. 1) found in American as well as in Spanish and Algerian pennyroyal oil the ketone, *pulegone.* This compound forms with hydroxylamine an oxime, $C_{10}H_{16}NOH.H_2O$, crystallizing in beautiful needles melting at 157° C., and with hydrogen bromide a crystalline compound melting at 40.5° C. The two compounds of the formula $C_{10}H_{18}O$, discovered by Kremers (*Ph. Rund.*, ix, p. 130), are also ketones and yield corresponding oximes.

American pennyroyal is a gently stimulant aromatic, and may be given in flatulent *colic* and *sick stomach,* or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flow when the system is predisposed to the effort. A large draught of the warm tea is in popular practice often given at bedtime, in recent cases of *suppression* of the *menses,* the feet having been previously bathed in warm water. The drug may be given in *doses* of two drachms (7.7 Gm.). The oil in *doses* of two to ten minims (0.12–0.6 cc.).

Hediosit. $C_7H_{12}O_7$.—It is the lactone or inner anhydride of *alpha-glucoheptonic acid,* $CH_2OH.(CHOH)_5COOH$. It occurs as white crystalline powder without odor, but with a sweet taste, but inferior to that of saccharin. It is readily soluble in both water and alcohol, its solution reacting to litmus as an acid. It has been brought forward as a substitute for sugar in the management of *diabetes.* It is asserted that that it has a food value equal to that of glucose, but does not increase the amount of sugar in the urine. According to the investigations of Lenel (*A. E. P. P.*, 1914, lxxvii, p. 335), only a very small proportion of the food value of hediosit, however, is utilized by the system. He found that from 25 to 75 per cent. might escape unchanged with the feces and of the remainder a very large proportion could be recovered unaltered in the urine.

Hedonal. *Methyl-propyl-carbinol-urethane.* $CH_3CH_2CH_2CH(CH_3)O.CO.NH_2$.—This is a white, crystalline powder of weak aromatic odor, fusing at 76° C., sparingly soluble in cold water, somewhat more so in boiling water, soluble in alcohol, ether, and other organic solvents. Decomposed by boiling with alkalies. It forms colorless crystals melting at 76° C. The solutions have a powerful menthol-like taste. Hedonal is believed to split up in the system into carbon dioxide, ammonia, and urea. Probably owing to the presence of the urea, it sometimes acts as a diuretic, but more usually it has no other effect than that of an hypnotic. It is claimed by de Moor that its diuretic action is much increased by its administration in solution. According to Dreser, in the dog it acts very feebly upon respiration and blood pressure. As an hypnotic it is mild in its action and but rarely produces disagreeable aftereffects. In severe cases of *insomnia,* or when the patient is kept awake by pain, it is of little service. No case of poisoning by it have been reported, and so far its prolonged use has not been followed by disagreeable symptoms. The *dose* is fifteen to forty-five grains (1.0–3.0 Gm.), given preferably in capsules half an hour before the desired effect.

Hedera. *Hedera Helix* L. *Ivy. English Ivy* (Fam. *Araliaceæ.*)—This well-known evergreen creeper and climber is a native of Europe, Asia and north Africa, climbing by aerial rootlets, with alternate, long-petioled, usually 3–5 lobed leaves, dark-green above and paler beneath. The fresh leaves have a balsamic odor, especially when rubbed, and a bitterish, harsh, unpleasant taste. They were formerly used for dressing issues, and, in the form of decoction have been recommended in *sanious ulcers* and *cutaneous eruptions*, particularly *tetter* and the *itch.* The berries, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. Posselt, in 1849, separated a principle which he called hederic acid but which Kingzetl (*P. J.*, 3rd s., viii, 205) showed to be a glucoside. J. Vernet (*Ber. d. Chem. Ges.*, xiv, 685) obtained a glucoside, which separated from solution in boiling acetone, in silky needles, melting at 233° C. This glucoside appears to be the substance studied by Moore (*J. P. Ex. T.*, 1913, iv) and which he called *hederin.* He assigned to it the formula $C_{32}H_{52}O_{10}$. Moore found that this principle belonged physiologically among the saponins; it has a strongly hemolytic action and although actively poisonous when injected subcutaneously appears to be harmless when taken through the stomach. Van der Haar isolated two glucosides, *hederin*, $C_{42}H_{66}O_{11}$, and *hederagenin*, $C_{31}H_{50}O_4$. (*A. Pharm.*, 1912, 424.) From the trunks of old ivy plants, growing in the south of Europe and the north of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum.* It is in pieces of various sizes, of a dark yellowish-brown color internally, of a vitreous fracture, pulverizable, yielding an orange-yellow powder, of a peculiar not disagreeable odor when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and other large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve *toothache.*

Hedychium. *Hedychium spicatum* Sm. (Fam. *Zingiberaceæ.*)—The root of this perennial herb, which is used in perfumery in India, has been found by J. C. Thresh to contain *ethylmethyl paracoumarate.* (*P. J.*, Nov. 8, 1884.)

Hegonon. *Silver Nitrate-ammonia-albumose.*—This is a light brown powder obtained by treating silver-ammonium-nitrate with albumose. It is readily soluble in water and contains approximately 7 per cent. of silver. It is used locally in the treatment of various forms of *gonorrhea* in concentrations of from 1 in 200 to 1 in 3000.

Helenium. *Helenium autumnale* L. (*H. grandiflorum* Nutt.) (Fam. *Compositæ.*) *Sneezeweed. False Sunflower.*—A tall, perennial herb indigenous to North America and usually found growing in moist situations. It has a rough, branching stem bearing alternate, lanceolate, mostly toothed leaves and terminal heads of yellow florets. The leaves and flowers snuffed up in the state of powder produce violent sneezing, and have been used as an errhine. Reeb found a crystalline bitter principle, *helenin,* with the formula $C_{20}H_{25}O_5$. This has been physiologically studied by Lamson (*J. P. Ex. T.*, 1913, iv) who found that it is an intense irritant to the mucous membranes, capable of causing a fatal gastro-enteritis, and that it acts as a paralysant to the heart and voluntary muscles. (This principle must not be confounded with "helenin" from Inula, which see in Part I.) *Helenium nudiflorum* Nutt. has similar properties; *H. tenuifolium* Nutt., a common roadside weed of Mississippi and Louisiana, is stated by Gallaway to produce in animals muscular twitchings, passing into violent convulsions, terminating in death. In four negroes *helenium* caused spasms with delirium and loss of consciousness. (*A. J. P.*, 1872, 309; D.C., 1907, 459.)

Helianthemum. *Rock-rose. Frostweed. Herbe de Hélianthème de Canada,* Fr. *Canadisches Sonnenröschen,* G.—"The dried herb of *Helianthemum canadense* (Linné) Michaux (Fam. *Cistaceæ.*" *N. F. IV.* *Frostwort* grows in all parts of the Eastern United States, preferring dry sandy soils. It has been omitted from the National Formulary V. The dried herb is employed in medicine and was described as follows: "Stems mostly less than 5 cm. in length, branched above, terete, frequently reddish, canescent, the slender branches mostly erect; leaves very short-petioled, from 1 to 3 cm. in length, and from 4 to 8 mm. in width, oblong to oblanceolate, with entire, revolute margins, green and somewhat rough on the upper surface, canescent underneath; flowers of two kinds, rarely present at the same time, the early ones mostly solitary, pedicelled, with bright yellow corolla, from 2 to 3 cm. in breadth, hairy calyx, about thirty stamens and a single three-carpelled pistil, producing an ovoid capsule, about 7 mm. in length; later flowers apetalous, clustered in the leaf-axils, nearly sessile, having but four stamens and producing a capsule about 4 mm. in length. Odor slightly aromatic; taste astringent and bitter." *N. F. IV.* William Crutcher (*A. J. P.*, 1888, 390) found in it volatile oil, wax, fatty oil, tannin, and apparently a glucoside crystallizing in white needles. Frostwort has an astringent, slightly aromatic, and bitterish taste, and appears to possess tonic and astringent properties; it was formerly employed in *scrofula, diarrhea,* and *secondary syphilis,* and locally as a gargle in *scarlatina,* and as a wash in *prurigo.* The *Fluidextractum Helianthemi* was recognized by the N. F. IV. and may be given in *doses* of one fluidrachm (4 cc.).

Helianthus. *Helianthus annuus* L. (Fam. *Compositæ*) *Common Sunflower. Hélianthe, Grand Soleil,* Fr. *Sonnenblume,* G.—The *Sunflower* has long been under cultivation in this and other countries both as an ornamental and economic plant. Its stems yield a fine textile fiber; its flowers furnish a yellow dye; its leaves are used for fodder, and its "seeds" (akenes) yield a fixed oil and are used for food.

The plant is a rough-hairy annual possessing a stem 3 to 12 feet high, broadly ovate to cordate, long-stalked, acute, coarsely serrate and 3-nerved leaves, large flower heads with yellow-ray and disk florets and 4-sided, laterally compressed akenes. The oil has a sp. gr. of from 0.924 to 0.926, solidifies at –15° C., is colorless or yellowish, limpid, nearly tasteless and odorless, and dries slowly. It is said to make an excellent salad dressing, and to be one of the best burning oils known. The increase in cultivation is stated to be nearly a thousandfold, 275 pounds of oil being a fair yield per acre. For particulars as to cultivation, see *A. J. P.*, 1875, 460; also *N. R.*, 1876, 165. Ludwig and Kromayer (*A. Pharm.* (2), 99, 1 and 285) obtained a tannin which they called *helianthitannic acid,* and gave it the formula $C_{14}H_9O_8$. On boiling with moderately diluted hydrochloric acid they obtained a fermentable sugar and a violet coloring matter. Buschmann obtained from the flowers of Russian helianthus, betaine and choline, he believed that their presence accounts for the observed activity of the extract. The stalk, when treated as is flax, yields a long, fine fiber, which is said to be used in China for the adulteration of silk.

Kazatchkoff states (*B. G. T.*, Oct., 1889) that in the Caucasus the inhabitants employ the sunflower in *malarial fevers* (see also C. D., 1919, xci, 1181). A tincture of the flowers and the leaves of the sunflower has been recommended by Beldau, in combination with balsamics, in the treatment of *bronchiectasis.* The Pah Ute Indians are said to use very freely as food the seeds of two indigenous sunflowers, *H. petiolaris* Nutt. and *H. lenticularis.* (*Proc. A. Ph. A.*, xxvii, 178.)

Helium. He–3.99.—This gaseous element was discovered in a gas yielded by deveite, a variety of uraninite, in 1895 by Ramsay. The spectrum showed it to be identical with the substance discovered in the solar chromosphere by Lockyer in 1868 which had been named by him helium, from the sun. A few months after Ramsay's discovery Kayser found the element as one of the rare gases of the atmosphere. It was later found as a constituent in natural gas from certain wells in Western America, and on account of its combination of qualities of lightness and non-inflammability it was collected for use in dirigible balloons. It is now collected for this purpose and stored for future use.

Helleborus. *Helleborus niger* L. *Black Hellebore. Hellébore noir,* Fr. *Schwarze Niesswurzel, Weihnachtswurzel, Winterrose,* G. *Elleboro nero,* It. *Eléboro negro,* Sp. (Fam. *Ranunculaceæ*).—*Black Hellebore* is a native of the mountainous regions of southern and temperate Europe, and is sometimes cultivated on account of the early opening and beauty of its flowers, whose expansion in midwinter has given to the plant the name of *Christmas rose.* Black hellebore is sometimes called *melampodium,* in honor of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of King Prætus by giving them the milk of goats fed on hellebore. For a history of the use of hellebore by the ancients, see 15th edition, *U. S. D.*

The plant is a perennial, acaulescent evergreen herb possessing a short, black rhizome which gives rise each year to a single, palmately-divided leaf and a flower stalk bearing one or two large white flowers that occasionally are flushed with purple.

The formerly official rhizome is irregular, tortuous, often branched and knotty in appearance, about 3 to 5 cm. long and 6 mm. thick; externally black; upper and lateral surfaces marked by short, erect branches possessing annulations from leaf scars and terminal buds or stem scars; lower surface exhibiting numerous root scars and short stumps of roots; fracture short; inner surface yellowish-white to yellowish, showing thick bark, radially-elongated narrow-wood wedges and large pith; odor slight; taste bitter and acrid. The rhizomes of various other plants, some not belonging to the same genus, are substituted for true hellebore. These have been examined by Tschirch and Neuber, who state their results as follows: The rhizome of *H. niger* exhibits a small pith and comparatively large acutely wedge-shaped, radially-elongated wood-bundles. The odor of the rhizome and roots is slight but rather pleasant, especially in the fresh drug. The rhizome of *H. viridis* L. has a large pith and tangentially extended, bluntly wedge-shaped or almost square wood-bundles; older roots exhibit a wood with from five- to seven-angular wedges. In both rhizome and root of *H. fœtidus* L., the wood is more strongly developed and radiate in appearance; it contains abundance of wood-fibers and encloses little or no pith. The rhizome of *Actœa spicata* L. is flattened and bears cushion-like protuberances, due to the remains of the aerial stems. The wood-bundles are thickened at either extremity and rounded by wood-fibers, so that in transverse section the wood-ring has a scalariform appearance. The root exhibits a regular three- to five-rayed wood, the rays being broader toward the outside. (*S. W. P.*, xl, 410.)

William Bastick discovered in black hellebore a crystalline principle, *helleborin,* $C_{36}H_{42}O_6$, of a bitter taste with a tingling effect on the tongue, not volatilizable, slightly soluble in water, more so in ether and alcohol, and more readily in these liquids hot than cold. (*P. J.*, xii, 274.) Marmé and Husemann obtained from the black and from the green hellebore (*H. viridis* L.) a glucoside, *helleborein,* $C_{26}H_{44}O_{15}$, by precipitating a solution of an extract of the root with solution of lead subacetate, freeing from lead by hydrogen sulphide, and again precipitating with phospho-molybdic acid; by boiling with acid it separated into glucose and *helleboretin,* $C_{14}H_{20}O_3$, a compound of a fine violet color. The helleboreïn exists both in the root and leaves. It has a taste at once sweet and bitter, is soluble in water and weak alcohol, much less so in ether and absolute alcohol, and is crystallizable in yellowish rhomboidal prisms. It is precipitable by tannic acid and mercurous acetate. (*J. P. C.*, 4e sér., ii, 258.) Husemann and Marmé (*Ann. Chem.*, cxxxv, 61) examined more thoroughly the *helleborin* of Bastick. They found that when boiled with diluted sulphuric acid, or, better, zinc chloride, it is converted into sugar and *helleboresin,* $C_{30}H_{38}O_4$. They obtain this glucoside by treating with hot water the green fatty matter which is dissolved out of the root by boiling alcohol. Though both helleborin and helleboreïn are poisonous, the products of their decomposition are said to be harmless.

Helleboreïn is strongly irritant to the mucous membranes, causing, when applied to the conjunctiva, redness, swelling, and increased secretion, with indirect enlargement of the pupil, and when applied to the nasal membrane, sneezing, though less than veratrine. Small doses produce little effect on the stomach; but, repeated and accumulated, they cause anorexia, nausea even to vomiting, pain, increased secretion, and inflammation both of the stomach and bowels. The experiments of Van der Haide (*A. E. P. P.*, 1885, xix), Trendelenburg (*A. E. P. P.*, 1909, lxi, p. 262) and others demonstrate that physiologically helleboreïn belongs to the digitalis group of drugs. In small doses it diminishes the rate of the pulse, increases the force and out-put of the heart, and causes a rise in the blood pressure. In toxic doses, the pulse becomes rapid, and small in volume, and the heart is finally arrested in systole. According to Cushny, the action of helleboreïn on cardiac inhibition is less than most of the other members of the digitalis group. The *helleborin* of Marmé and Husemann is a more active poison, though less irritant to the mucous membrane. It acts on the tongue like aconite. Its influence appears to be directed especially to the nervous system. In the lower animals it causes quickened breathing, restlessness, tension and trembling of the muscles, uncertainty of movement; then retardation of the breathing and pulse, irritability of the peripheral nerves, dilatation of the pupil, loss of hearing, and finally almost complete anesthesia, with cerebral and spinal congestion, even to apoplexy.

Hellebore was formerly used as a drastic purge in *doses* of from ten to twenty grains (0.65–1.3 Gm.). This employment has, however, justly passed out of vogue. It was highly esteemed by the ancients in *mania, dropsy,* and *epilepsy. Bacher's pills,* celebrated for the cure of *dropsy,* consisted chiefly of black hellebore. The glucoside helleboreïn has been used internally as a cardiac tonic in *doses* of from one-sixth to one-third of a grain (0.010–0.021 Gm.) several times a day, but its irritant action on the stomach militates against its practical usefulness. Ischistowitsch (*Cb. M. W.*, 1887) has used an aqueous extract of hellebore with apparent benefit in *heart diseases.* Venturini and Gaspairini (*B. G. T.*, June, 1888) states that helleboreïn is a local anesthetic, which, in affections of the eye, is preferable to cocaine, because of the great permanency of the anesthesia, and because neither the pupil nor the intra-ocular pressure is affected. They use from three to four drops of a solution, each drop of which represents one one-hundred and sixty-fourth of a grain (0.0004 Gm.). In overdoses hellebore produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The *dose* of the powdered root is two or three grains (0.13–0.2 Gm.).

Hemidesmus Root. *Br.* 1898. *Hemidesmi Radix. Indian Sarsaparilla. Nunnari. Racine de Hemidesmus,* Fr. *Hemidesmus-Wurzel,* G.—"The dried root of *Hemidesmus indicus* R. Br." *Br.*, 1898. *Hemidesmus indicus* (Fam. *Asclepiadaceæ*) is a climbing shrub native to India and Ceylon. It has twining, woody, slender stems, and opposite, petiolate leaves, which are entire, smooth, shining, and of a firm consistence. The leaves vary much in size and shape, some being linear and acute, others broad-lanceolate, and others again oval or ovate. The flowers are small, green on the outside, purple within, and disposed in axillary racemes. The fruit consists of two long, slender, spreading follicles. This plant is common over the whole peninsula of Hindostan. The official portion was the root, which has long been used in India as a substitute for sarsaparilla. It is 30 cm. or more long and from 3 to 6 mm. thick, rigid, tortuous, cylindrical, and little branched, consisting of a large yellow ligneous center, and a brownish, corky bark, marked with longitudinal furrows and transverse fissures. The odor is aromatic, recalling that of tonka bean, the taste is aromatic and sweetish. On one side of the root the cork is frequently separated from and raised above the cortex, and is transversely fissured. The transverse section exhibits numerous laticiferous cells in the cortex. For details of microscopic structure, see *P. J.*, 1872, 62. Garden obtained from hemidesmus a peculiar, volatilizable acid principle, which he named *smilasperic acid,* under the erroneous impression that the root was derived from *Smilax aspera.* Pereira proposed to call it *hemidesmic acid.* Scott also obtained a stearopten by distillation with water, presumably the same material. It has not been further investigated.

Hemidesmus root is said to be tonic, diuretic, and alterative. It was introduced into Great Britain from India, and was employed for some time under the name of *Smilax aspera.* It is used for the same purposes as sarsaparilla. The native practitioners in India are said to employ it in nephritic complaints, and in the sore mouth of children. It is used in the form of infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint (500 cc.) may be given in wineglassful doses in the course of the day. A *syrup* was official in the Br., 1898.

Hemoglobin. *Hæmoglobin.*—A constituent of venous blood, passing in the arterial blood into *oxyhemoglobin.* Its molecular formula is very complex. It is a conjugated protein, consisting of the protein, *globin,* in combination with the chromatogenic substance, *hematin.* It is readily obtained in a crystalline state and the crystals are said to vary in form according to the kind of animal from whose blood they are prepared. The principle property of hemoglobin is its power of combining with gases, especially oxygen and carbon monoxide. Whereas the oxygen compound readily dissociates, the carbon monoxide compound is very stable and cases of poisoning from illuminating gas where much carbon monoxide is present, as in the instances where it consists partly of water gas, are therefore often fatal. Various preparations of *desiccated blood* containing hemoglobin have been put upon the market. Crystals of hemoglobin may be obtained from the blood of certain animals (guinea-pigs, rats, etc.) with ease by simply adding water to the blood. The hemoglobin dissolves in the water, the corpuscles separating, and the crystals form in a few minutes. Another method consists in adding to defibrinated blood 6 per cent. of its volume of ether, or a mixture of alcohol and ether; on shaking the mixture, the corpuscles dissolve, and a thick magma of crystals forms sooner or later; these may be purified by washing with 25 per cent. alcohol and by recrystallization. Freezing has been resorted to for the purpose of separating the crystals.

Ferrohemol is a brown, almost tasteless powder containing 3 per cent. of iron, which is made by the precipitation of blood by a dilute solution of iron and neutralization with soda. *Fer cremol* is a similar substance.

Hemol and *Hemogallol* are made, as suggested by Kobert, by the action of reducing agents upon the blood coloring matter. (See *E. Merck's Jahresber.*, 1891.) With the hemol, zinc dust is used as the reducing agent; with the hemogallol, pyrogallol is used. The former is a dark brown, the latter is a reddish-brown, tasteless powder.

Either of these blood derivatives may be employed instead of the older preparations of iron. There is sufficient clinical evidence to show that they are effective ferruginous tonics which may be, as is claimed for them, less constipating and less disagreeable to the stomach than are the older preparations of iron; but there is no sufficient reason for believing that they have any real superiority. *Dose*, five to ten grains (0.32–0.65 Gm.).

A number of hemol preparations have also been recommended by Kobert and prepared by Merck & Co., such as *arsenhemol, bromhemol, iodohemol, iodomercuryhemol*, and *copperhemol*.

Heracleum. *Heracleum lanatum* Michx. *Common Cow-parsnip.*—This is a coarse, pubescent, perennial umbelliferous herb growing on moist, low grounds in northern North America as far south as North Carolina. Its grooved stem attains a height of 6–8 feet and bears ternate leaves with irregularly toothed leaflets and large umbels of white flowers.

The root, which is the part used, bears some resemblance to that of common parsley. It has a strong disagreeable odor and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Bigelow considers the plant poisonous. It appears to be somewhat stimulant and carminative, and has been used in *epilepsy*. (See 16th edition, *U. S. D.*)

Heretine.—An ether-soluble alkaloid obtained from *Heritiera javanica* (Fam. *Sterculiaceæ*), is said to be effective in the treatment of *epilepsy, chorea* and *migraine*.

Hermodactyls. *Hermodactyli.*—Under this name are sold in European commerce the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is thought to be a *Colchicum*, and *C. variegatum* L., a native of the south of Europe and the Levant, is particularly indicated by Fée, Geiger, and others, while by authors, no less eminent, the roots are confidently referred to *Iris tuberosa* L. They certainly bear a considerable resemblance to the corm of *Colchicum autumnale* L., being heart-shaped, channelled on one side, convex on the other, and from 12 to 25 mm. in length by nearly as much in breadth. As found in commerce, they are destitute of the outer coat, are of a dirty yellowish or brownish color externally, white and amylaceous within, inodorous and nearly tasteless, though sometimes slightly acrid. They are often wormeaten. Their chief constituent is starch, and they contain no veratrine or colchicine. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum. They are in fact almost without action upon the system. It is doubted whether they are the *hermodactyli* of the ancients, which acted like colchicum and were useful in *gout* and *rheumatism*. Pereira describes a bitter variety of hermodactyls, which was brought from India by Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance.

Hermophenyl. *Sodio-mercuric Phenoldisulphonate. Mercurio-sodic Phenol-disulphonate.*—This substance, which contains 40 per cent. of metallic mercury, occurs as a white amorphous powder, freely dissolving in cold water (up to 22 per cent.). According to Lumiere and Chevrotier (*B. M. J.*, 1901, 690), it possesses very feeble toxic properties, while it is actively bactericidal. Its hypodermic injections are said to cause but little pain. Hermophenyl is used in the treatment of *syphilis*. It may be exhibited either by intramuscular injection or, in pill form, by the mouth. The *dose* is ordinarily from one-eighth to one-third of a grain (0.008 to 0.021 Gm.) which, when administered by the mouth is given several times a day, by injection, once a day. Bernard claims that it may be made into a 1 per cent. soap without decomposition, affording an excellent preparation for rendering the hands aseptic. The 2 per cent. aqueous solution may be used for surgical purposes.

Herniaria. *Herniaria glabra* L. (Fam. *Caryophyllaceæ*) *Herniary. Rupture-wort. Knot-weed. Breastwort. Bruchkraut, Tausendkorn, G.*—A small perennial European herb about 2 inches high and producing, when a number of plants are grown together, a dense carpet of moss-like leaves which turn bronze-red in winter. Its flowers are inconspicuous and greenish. Goblez has obtained from this plant a crystalline principle, *herniarine* (*J. P. C.*, 4e sér., xx, 270), which proved to be *methylumbelliferone*, $C_{10}H_8O_3$. Schneegans has also discovered an alkaloid, *paronychine*. (*A. J. P.*, 1890, 488.) Besides these it contains a saponin which was discovered by Schulz in 1896. This saponin is strongly hemolytic, 1 part in 40,000 being sufficient to dissolve the coloring matter from the red blood cells. It appears to be absorbed unchanged and after its absorption to stimulate the kidneys. According to Kobert this plant, as well as the allied *Herniaria hirsuta* L., contains an acid and a neutral saponin both of which are diuretic.

Herniaria is recommended by Zeissl in *catarrh of the bladder*. Very active diuretic properties have been attributed to it by Kuhn (*Med. Klin.*, 1908) and others, who have found that it was successful in the treatment of *dropsy*, whether of cardiac or nephritic origin.

Heteromeles. *Heteromeles arbutifolia* (Poir.) Roem. (Now ascribed to *Photinia arbutifolia* Lindl.) (Fam. *Rosaceæ.*) D. D. Lustig has found in this California plant (*toyon* of the Indians) tannic, gallic, and hydrocyanic acids. (*A. J. P.*, April, 1882.)

Hetocresol. *Metacresol Cinnamate. Cinnamometacresol.* $C_6H_5CH = CH.COOC_6H_4CH_3$.—Forms crystals melting at 65° C., insoluble in water, but soluble in alcohol, ether, benzene, chloroform, and glacial acetic acid. It is claimed that this substance is especially valuable as a local remedy in external *tuberculosis*. In tuberculosis of the bladder Landerer uses, after cocainization, 1.4 per cent. solutions containing 0.7 per cent. of common salt. Fistulous tracts he injected with hetocresol, 1 part; iodoform, 2 parts; water, 1 to 8 parts. In *scrophuloderma*, after scraping, hetocresol has been found to be very useful.

Heuchera. *Heuchera americana* L. *Alum Root. American Sanicle. Racine d'Heuchère d'Amérique*, Fr. *Amerikanische Sanikelwurzel*, G. (Fam. *Saxifragaceæ.*)—This is a perennial, herbaceous plant which grows in shady, rocky situations from New England to Carolina and westward to eastern Kansas. The rhizome, which was formerly official, is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. J. Peacock (*A. J. P.*, 1891, 174) found a percentage of tannin ranging from 9.33 to 19.66 reckoned on the dry drug, according to the season of the year when collected; also a percentage of starch, calculated the same way, ranging from 5.17 to 16.32. Frederick Stearns (*Proc. A. Ph. A.*, 1858, 263) speaks of two other indigenous species, *H. villosa* Michx. (*H. caulescens* Pursh.) and *H. pubescens* Pursh., as having similar properties; and F. W. Anderson reports (*Botan. Gaz.*, 1887, 65) that the roots of *H. hispida* Pursh., *H. cylindrica* Douglas, and *H. parvifolia* Nuttall are much used by hunters of Montana and others as astringents, particularly in *diarrhea* caused by the drinking of alkali water.

Hexamethylene-tetramine Compounds.—There have been introduced an extraordinary number of combinations of hexamethylenamine. Some of the more important of these are considered below.

Hexamethylene-tetramine Bromethylate. Bromalin. Bromethylformin. $(CH_2)_6N_4C_2H_5Br$.—Formed by the action of ethyl bromide upon hexamethylene tetramine. It occurs in colorless scales or white powder, melting at 200° C. with decomposition; nearly tasteless, readily soluble in water. Bromalin has been used by a number of neurologists as a substitute for the alkaline bromides in the treatment of *epilepsy.* It is asserted that it exercises all of the beneficial effects of the bromides in this disease, but does not give rise to symptoms of bromism. These statements, however, are hard to credit, as Bermann and Bilinski (*Th. M.*, 1910) have found that the compound is broken up in the body, and the entire content of bromine appears in the urine as an alkaline bromide. Broma represents 32 per cent. of bromine and is ordinarily administered in *doses* of thirty to sixty grains (2–4 Gm.).

Hexamethylene-tetramine Camphorate. Amphotropin. N. N. R. 1924. $((CH_2)_6N_4)_2.C_8H_{14}(COOH)_2$.—A molecular combination of camphoric acid and hexamethylene-tetramine. This is a white, crystalline powder easily soluble in both water and alcohol. It is used as a urinary disinfectant. *Dose,* eight to fifteen grains (0.5–1 Gm.).

Hexamethylene-tetramine Methylene Citrate. Uropurgol. Helmitol. Citramine. $C_7H_6O_7.(CH_2)_6N_4$.—This substance is a white acidulous, odorless powder, soluble in water, but almost insoluble in alcohol. It is said to be a combination of anhydromethylene-citric acid and hexamethylene-tetramine, 2 Gm. representing 0.85 Gm. of the latter constituent. Theoretically, helmitol should undergo decomposition in the human system with the formation and subsequent elimination of formaldehyde, and S. Goldschmidt (*Th. M.*, Jan., 1903) states that after the administration of helmitol formaldehyde is present in the urine when freshly voided. Helmitol has been highly recommended by P. Rosenthal (*Ther. Geg.*, Dec., 1902) in chronic *gonorrhea* and other infective diseases of the genito-urinary tract. Its value has been confirmed by S. Goldschmidt. It may be given in *doses* of fifteen to twenty-three grains (1.0–1.5 Gm.) up to forty-five to sixty grains (3–3.9 Gm.) a day.

Hexamethylene-tetramine Resorcinol. Hetralin. Dioxybenzene-hexamethylenetetramine. $C_6H_6O_2C_6H_{12}N_4$.—Soluble in four parts of hot water and in fourteen of cold water. Contains 60 per cent. of *hexamethylenetetramine.* It has been used as a urinary antiseptic in precisely the same class of cases in which hexamethylenamine has been employed. Fries (*All. M. C. Z.*, 1906) asserts that it has an advantage over the latter, in that it exercises an antiseptic influence even in alkaline fluids. Birnbaum (*W. K. R.*, 1906) asserts that it is also a valuable remedy in *spermatorrhea* and allied complaints. The *dose* is from eight to fifteen grains (0.5–1.0 Gm.) three times a day.

Hexamethylene-tetramine Salicylate. Saliformin. $C_8H_{12}N_4.C_6H_4OH.COOH$.—A white crystalline powder of a pleasant acidulous taste. Easily soluble in alcohol and water. It is employed as a uric acid solvent and genito-urinary antiseptic. *Dose,* eight to thirty grains (0.5–2.0 Gm.).

Hexamethylene-tetramine Quinate. Quinotropin. Urotropin Quinate. Chinotropin.—This quinine compound is furnished commercially in two forms, Quinotropin I, containing 73 per cent. quinic acid and 27 per cent. urotropin, Quinotropin II, containing 80 per cent. quinic acid and 20 per cent. urotropin. These compounds yield aqueous solutions of an acid, agreeable taste. According to Nicolaier and Hagenberg (see also De la Camp, *M. M. W.*, 1901, No. 30), quinotropin does not decrease the excretion of uric acid but aids in its solution in the urine. *Dose,* Quinotropin I, twenty-five to fifty grains (1.6–3.2 Gm.) per day; Quinotropin II, fifty to seventy-five grains (3.2–5.0 Gm.) per day.

Hexamethylene-tetramine Sulphosalicylate. Hexalet. Sulphosalicylate Hexamethylenamine. Hexal. Sulphexine. Sulphexet. $(CH_2)_6N_4.SO_3H.C_6H_3(OH)COOH$, occurs as white crystals soluble in water with a pleasant acid taste. It is claimed for it that it is broken up in the system, and that the sulphosalicylic acid exercises an astringent action upon the mucous membrane of the bladder as well as enhances the antiseptic action of the hexamethylenamine portion of the molecule. The *dose* is from ten to twenty grains (0.65–1.3 Gm.) three times a day.

Hexamethylene-tetramine Sodium Acetate, Cystopurin.—A double salt of hexamethylenamine and sodium acetate in the molecular proportion of 1:2 which, according to Bergell (*Apoth. Zeit.*, xxii), has the following formula: $(CH_2)_6N_42CH_3COONa + 6H_2O$. This salt forms long, acicular crystals which are soluble in cold or warm water. This compound has been employed as a urinary antiseptic in *cystitis, pyelitis,* and similar conditions. It is asserted by one authority that its advantage over hexamethylenamnie is that the formaldehyde is more slowly liberated and by another because the sodium acetate hastens the liberation of formaldehyde.

Hexamethylene-tetramine Tannin. Tannopin.—A light brown, odorless and tasteless powder, insoluble in alcohol, water and ether, and soluble in alkalinated liquid. It contains 87 parts of tannic acid and 13 parts of hexamethylamine-tetramine. It is employed as an intestinal astringent and antiseptic. *Dose,* eight to fifteen grains (0.5–1 Gm.).

Hexamethylene-tetramine Tetraiodide. Siomine.—This compound is insoluble in water and contains 78.5 per cent. of iodine. It is said to be decomposed in the intestines with the liberation of its two constituents. It is used in medicine chiefly for its iodide action.

Hexamethylene-tetramine Triborate. Borovertin. $(CH_2)_6N_4.3HBO_2$.—It is prepared by the direct combination of boric acid and formin. A white powder, slightly acid in its reaction, it is soluble in eleven parts of water and almost insoluble in alcohol and ether. On heating with acids formaldehyde is developed; on saturation with alkalies ammonia.

It is asserted to have the advantage over hexamethylenamine that it of itself renders the urine acid and therefore leads to the splitting up of the hexamethylenamine molecule and the liberation of formaldehyde, so that it is useful as an urinary antiseptic, when the urine is alkaline as well as when it is acid.

The *dose* is five to ten grains (0.32–0.65 Gm.) three or four times a day.

Hibiscus. *Hibiscus Abelmoschus* L. (*Abelmoschus moschatus* Mœnch.) (Fam. *Malvaceæ.*)—An annual or biennial plant indigenous to India but cultivated in many tropical countries. It yields the seeds known under the names of *Semen Abelmoschi* (*grana moschata, Musk seed, Graine d'Ambrette, Ambrettekörner, Bisornkörner*). These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown color, of an odor like that of musk and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic, but are now used only in perfumery. The Arabs flavor their coffee with them. They are said to be employed in the adulteration of musk. Another species, *Hibiscus esculentus* L. (*Abelmoschus esculentus* Moench.), is cultivated under the name of *okra, bendee,* or *gumbo* in various parts of the world, for the sake of its capsular fruit, which abounds in mucilage (*gombine*), and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices. The roots, which are a foot or two long, are said also to abound in mucilage free from any unpleasant odor. Their powder is perfectly white, and superior to the marshmallow. The plant is sold, in some parts of the United States, in the vegetable markets. The bark is also used in making paper and cordage.

Hieracium. *Hieracium venosum* L. (Fam. *Compositæ.*) *Rattlesnake Weed. Poor Robin's Plantain. Eperviere,* Fr. *Habichtskraut,* G.—The plant is a common perennial herb, growing in dry places and open woods from Maine to Georgia and westward. It is characterized by having a rosette of radical leaves which are elliptic-oblong, smooth and often purple veined or mottled above and glaucous beneath. It bears bright yellow ligulate flowers in heads. The leaves and roots are thought to possess medicinal virtues, and, being deemed astringent, have been used in *hemorrhagic diseases.* The juice is supposed by some to have the power of removing *warts. Dose* of infusion (two ounces to the pint), a wineglassful (60 cc.).

An allied species, *Hieracium pilosella* (*Mouse-ear Hawk-weed*), was used in the Middle Ages to cure hernia and dissolve calculi. Leclerc (*B. Sc. Pharm.*, 1922, xxix, p. 30) has found that it possesses diuretic properties and has used a fluid extract in doses of 2 cc. (30 minims) in various types of *edema* with asserted benefit.

Hippuric Acid. $C_6H_9NO_3$. *Benzoylglycocoll,*  $CH_2<\begin{matrix}NH.C_7H_5O\\COOH\end{matrix}$.—This occurs in considerable amount in the urine of herbivorous animals, sometimes in that of man. Benzoic and cinnamic acids, toluol, and other aromatic substances, when taken internally, are eliminated as hippuric acid. It crystallizes in rhombic prisms, melting at 187° C. and at about 240° C. decomposes into benzoic acid, benzonitrile, and prussic acid. Boiling acids, alkalies, or high temperatures decompose it into benzoic acid and glycocoll. According to the experiments of Meissner and Shepard, hippuric acid injected into the blood of animals acts as a very decided poison, but the hippurates have been suggested by Garrod as a remedy in the *uric acid diathesis.* He affirms that if outside of the body the sodium hippurate be added to blood serum that shows the presence of a urate, the latter is soon removed. *Sodium hippurate* may be combined with lithium or potassium salts; the *dose* is ten grains (0.65 Gm.) three times a day.

Hirudin. *Hirudine.*—A principle obtained from the heads of leeches which prevents the coagulation of blood. It occurs as brownish scales easily soluble in water. One-sixtieth of a grain is said to permanently prevent two fluidrachms of blood from coagulating without changing its property in any other way. Its use in gynecology is based on this property. See *Hirudo,* Part I. Marshall (*J. P. Ex. T.*, 1915, vii, p. 157) finds that some commercial samples of *hirudin* are highly toxic. He believes that these effects are due to the presence of decomposition products.

Histamine. *Ergamine. Betaiminazolylethylamine.* .—Histamine chemically is histidine minus one molecule of carbon dioxide. Histamine hydrochloride is used as a reagent for standardizing pituitary preparations. Histamine occurs in various putrefying proteins and also in ergot. The commercial supply, however, is obtained synthetically. It is a general stimulant to unstriped muscle, including the uterus, but through some action upon the blood vessels not clearly understood, it produces a fall of blood pressure. It also produces, in rodents, a spasm of the bronchial muscles, giving rise to symptoms very analogous to those of the so-called anaphylactic shock. (See Abel and Kubota, *J. P. Ex. T.*, 1919, xiii, 243.) It has been suggested as a uterine stimulant in *postpartum hemorrhage.* The *dose* of histamine is one-sixtieth of a grain (0.001 Gm.).

Histogenol.—Monneyrat (*Prog. M.*, April, 1902), finding that *sodium methylarsenate* ($OAsCH_3O_2Na_2$) was not poisonous, has combined it with nucleinic acid to form this preparation, which he claims to be of great value in the treatment of *tuberculosis.*

Hoang-Nan.—This is the bark of *Strychnos malaccensis* Benth. (Fam. *Loganiaceæ*), a climbing plant, which grows in Malacca and surrounding countries. Brucine and strychnine are stated to have been found in it, brucine being the more abundant of the two. It has been found to produce in animals general tetanic spasms similar to those caused by strychnine. It probably has the same range of medicinal application as has nux vomica, although special virtues have been claimed for it in the treatment of *chronic skin diseases. Dose* of powdered bark, three grains (0.2 Gm.).

Holadin. *N. N. R.* 1924. *Extractum Pancreaticum Integrum.*—A dried extract of the entire pancreas containing all the constituents of the glands and having power to digest starch and proteids and to curdle milk, also aiding in the splitting up of fats. *Dose,* three to ten grains (0.2–0.6 Gm.).

Holigarna. *Holigarna longifolia* Roxb. Now *Senecarpus longifolia* Blume. (Fam. *Anacardiaceæ.*)—According to David Hooper (*P. J.*, xxv, 1895), the black juice of this tree, which is used in India as the basis of a varnish, is actively vesicant, and contains a body closely allied to, if not identical with, cardol.

Homorenone. *Ethylamino-acetopyrocatechin.* $C_6H_3(OH)_2CO.CH_2NH_2.C_2H_5$.—The hydrochloride occurs as bitter white crystals, readily soluble in water with a melting point of 260° C. It is asserted to resemble closely the physiological action of epinephrine except that it requires solutions of greater concentration to produce the same result. A 5 per cent. solution is asserted to be equivalent to one per thousand of epinephrine. (See *P. J.*, 1908, lxxx, p. 784.)

Honthin.—This is a grayish-brown odorless and tasteless powder, insoluble in water but yielding a light-brown solution in alcohol and in aqueous alkali, in which it is partly soluble. It is said to be chemically a *keratinized albumin tannate.* It is given in *doses* of from ten to twenty grains (0.65–1.3 Gm.) three to five times daily, as an astringent, in all forms of *diarrhea* without great irritation.

Hoochinoo.—This is an alcoholic drink which is clandestinely distilled by the Alaskan Indians, and has been supposed, on account of the frenzy which it produces in them, to contain some poisonous substance other than alcohol. John Marshall found it, however, to be simply an alcoholic liquor of about the strength of sherry, *i. e.*, between 20 and 25 per cent.

Hordenine. *Para-oxyphenyl-dimethyl-ethylamine.* $C_{10}H_{15}ON$.—It was isolated by Léger from malted barley. The sulphate, crystallizes in prismatic needles giving a violet-blue color with ferric chloride.

Hordenine has been used by Sbrazes and Guerive (*C. R. A. S.*, 1908, cxlvii) and other authors, in the treatment of various forms of *diarrhea* and *dysentery* and in gastric hyper-secretion. According to the researches of Camus (*A. I. P. T.*, 1906, xvi), which are reported by the authors quoted, it would appear that it acts by paralyzing the peripheral ends of the secretory nerves, as does atropine. It appears to affect also the pneumogastric and motor nerves and is asserted to have a tonic action upon the heart. Jackson (*J. P. Ex. T.*, 1914, iv, p. 491) finds that hordenine has a powerful effect in overcoming bronchial spasm and suggests its use in *asthma.* We know, however, of no clinical trials of it in this condition. The *dose* is three to eight grains (0.2–0.5 Gm.) three or four times a day.

Hordeum. *Barley. Orge,* Fr. *Gerste,* G.—The grains of cultivated varieties of *Hordeum vulgare* L. and *H. distichon* L. (Fam. *Gramineæ*). The original country of the cultivated barley is unknown. The plants have been found growing wild in Sicily and in various parts of the interior of Asia. *Hordeum vulgare* yields the six- and four-rowed barleys and *H. distichon*, the two-rowed barleys. There are several forms of each of these under cultivation. A form of four-rowed barley, *Hordeum vulgare pallidum,* is the common barley in Northern America, Europe and Asia.

Clifford Richardson (*Bulletin No. 9, Department of Agriculture,* 1886) gives the following as the average composition of American barley: water, 6.47 per cent.; ash, 2.87; oil, 2.67; sugar, etc., 7.02; dextrin and soluble starch, 3.55; starch, 62.09; albuminoids soluble in 80 per cent. alcohol, 3.66; albuminoids insoluble in 80 per cent. alcohol, 7.86; fiber, 3.81; total, 100.00. He finds, moreover, that on an average the grain makes up 84.78 per cent. and the hull 15.22 per cent. of the barley. Kühnemann (*B. Chem. G.*, 1875 and 1876), found a crystallized dextrogyrate sugar which did not reduce alkaline copper solution, and an amorphous lævogyrate mucilaginous substance called *sinistrin.* According to Kühnemann, barley does not contain dextrin.

Barley contains *hordein,* a proteid substance somewhat related to *gliadin* which is derived from the kernels of wheat and rye. Hordein is soluble in alcohol. The name was formerly given to a pulverulent mixture obtained from barley which was believed to be a definite substance.

Hulled barley is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18.75 parts in the hundred.

Barley meal is formed by grinding the seeds, previously deprived of their husk. It has a grayish-white color; the constituents are the same as described above for barley. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

Pearl barley (*Hordeum decorticatum,* Br., 1885) is the seed deprived of all its investments and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper form of barley for medicinal use.

Barley in the form of the decoction, popularly known as *barley water,* affords a mucilaginous drink much employed from the time of Hippocrates to the present. Pearl barley is the form usually preferred for the preparation of the decoction, made by pouring four pints of boiling water on two troyounces of pearl barley and boiling away to two pints, and straining. It is especially used in infant feeding, as it seems to prevent the formation of large milk curds by its colloidal character.

Hormonal. *Peristaltic Hormone.*—It has been demonstrated that certain substances are formed in the body which, being absorbed into the blood, act as stimulants to secretion in distant glands. The presence of these metabolic products, which are known to physiologists as *hormones,* is generally presumed to be essential for normal function. Zuelzer (*B. K. W.*, 1908) claimed to have demonstrated that there is formed in the cells of the mucous membrane of the stomach, a hormone which is an excitant to intestinal peristalsis, and that this hormone is stored in the spleen. He has accordingly brought forward as a remedy for *constipation,* under the name of *hormonal,* a preparation, made from the spleen of an animal at the height of digestion, which is intended for intravenous injection. A number of authors have reported favorably on its effects, but there have been several cases of serious and even fatal collapse following its application. Zuelzer (*D. M. W.*, xxxviii) asserts that these mishaps have been due to errors in the manufacture by which the substance was contaminated with an albumose, and that since the discovery and correction of these there has been no further trouble. On the other hand, Dittler and Mohr (*Z. K. M.*, 1911, lxxv) from both laboratory and clinical observations, conclude that the remedy is of doubtful utility, and too dangerous for practical use.

Huamanripa.—This is a Chilian drug, the plant growing on the slope of the Cordilleras at considerable heights. Lapater found it to be stimulating, emetic, sialagogue, and diaphoretic. (*West. Drug.*, 1886, 410.)

Hura. *Hura crepitans* L. *Sandbox tree. As-*

sacou. Sablier, Fr. *Sandbüchsenbaum*, G.—This tree, belonging to the *Euphorbiaceæ*, is indigenous to tropical America and is extensively cultivated in the tropics. It is characterized by the tendency of its capsular fruit when ripe to break with violence into several pieces, and thus scatter the seeds. It is an acrid emeto-cathartic; in large doses acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark all have these properties; an oil expressed from the seeds is actively purgative. According to Richet, the toxicity is due to the presence of a toxalbumin to which he gave the name of *crepitin*. (*P. J.*, 1910, lxxxiv, p. 571.) The juice of *Hura crepitans*, according to J. J. Surie (*Nederl. Tijdscgvoor Pharm.*, 1900, 107), contains a volatile, colorless liquid, *hurin*, closely allied to cardol, and is stated by Martius to be used to intoxicate fish. It has been employed to a considerable extent with alleged favorable results in the treatment of the *elephantiasis*, or *leprosy*, in Brazil. (For a method of using it, see *J. P. C.*, xiv, 424.) The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; the natives are said to employ it in the preparation of a poison.

Hychlorite. *N. N. R.* 1924.—A solution of chlorinated soda each 100 Gm. of which is said to contain sodium hypochlorite 4.05 Gm., sodium chloride 3.20 Gm., and calcium hydroxide 0.17 Gm.

This solution represents 3.85 per cent. of available chlorine, being, therefore, of approximately the strength of liquor sodi chlorinata. Its chief importance lies in the comparative slowness of its deterioration; the available chlorine content decreases at the rate of about 12 per cent. per annum. It is also of very much lower alkalinity and for this reason it is used as a surgical disinfectant.

Hydracetin. *Pyrodine.*—The *hydracetin* of commerce is stated to be a varying compound, whose active principle is *acetylphenylhydrazin* (C_6H_5,-NH–NH.C_2H_3O). It is soluble in alcohol and in water in proportion to 1 to 50. According to Guttmann (*Ph. Centralh.*, May 16, 1889, 311), hydracetin is a powerful antipyretic and antirheumatic remedy. It occurs as a white, odorless, almost tasteless crystalline powder, melting at from 128°–129° C. It is stated that it cannot be continuously used without danger. Externally, hydracetin is used in place of chrysarobin in *psoriasis* and similar disorders, in an ointment of from 5 to 15 per cent. *Dose*, three-quarters of a grain (0.048 Gm.) two or three times a day.

Hydrastinine Hydrochloride. *Hydrastininæ Hydrochloridum*, U. S. IX.—This salt, which was formerly official was defined as "The hydrochloride $[C_{11}H_{11}O_2N.HCL = 225.57]$ of hydrastinine, an alkaloid obtained by the oxidation of hydrastine. Preserve it in well-closed containers, protected from light." *U. S.*

It is an artificial alkaloid, produced by acting on hydrastine, the alkaloid from hydrastis, with oxidizing agents. When manganese dioxide and sulphuric acid are used together, or when platinic chloride is employed, hydrastinine and *opianic acid* are the products. Hydrastinine is also manufactured synthetically from narcotine by first producing cotarnine, which is reduced to *hydrohydrastinine* and the latter subsequently oxidized to hydrastinine.

It can also be made from berberine, from piperonal or from *homopiperonylamine.*

Hydrastinine hydrochloride was officially described as in "light yellowish needles, or as a yellowish-white, crystalline powder without odor. One Gm. of Hydrastinine Hydrochloride dissolves in 195 cc. of chloroform, and in 1820 cc. of ether at 25° C.; very soluble in water and alcohol. Its aqueous solution (1 in 20) is neutral to litmus and shows a blue fluorescence, especially when highly diluted. It melts at about 210° C. with partial decomposition. In an aqueous solution of the salt (1 in 20), potassium dichromate T.S. produces a precipitate which redissolves if gently heated, but on cooling the solution it separates again in glistening needles. Silver nitrate T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in nitric acid. No weighable ash remains on incinerating 0.1 Gm. of Hydrastinine Hydrochloride. In an aqueous solution of the salt (1 in 20) bromine T.S. produces a yellow precipitate, which is completely soluble in ammonia water, producing an almost colorless solution (*hydrastine*). Add a few drops of ammonia water to 1 cc. of an aqueous solution of Hydrastinine Hydrochloride (1 in 20); no turbidity is produced (*foreign alkaloids*). Add slowly 4 or 5 drops of a solution of sodium hydroxide (1 in 7) to a solution of 0.2 Gm. of the salt in 3 cc. of distilled water; each drop causes a milky turbidity, which disappears again on shaking (*foreign alkaloids*). From this solution, after standing for some time, pure white hydrastinine separates, and the supernatant fluid is almost colorless." *U. S.*

Uses.—Hydrastinine is, when given in large enough amount, a powerful depressant to the whole motor tract, affecting the psycho-motor centers of the cerebral cortex, the motor nerve, and the muscle itself. In the present state of our knowledge it is uncertain whether the depression is or is not preceded by a brief period of excitation, but it is almost certain that there is a primary stimulation of the muscles. The alkaloids slows the action of the heart but increases the force of the beat, and markedly augments the blood pressure, contracting actively the blood vessels by stimulating both the vaso-motor centers and the muscles in the walls of the arterioles. In the toxic dose it finally paralyzes respiration, although there is reason for believing that in the beginning it stimulates the function. Death occurs from asphyxia, to which it usualy ascribed the final fall of the arterial pressure.

It has a direct stimulant action upon the uterus. According to Kehrer (*Monatsschr. Geburtsh. u. Gynäk.*, 1907, xvi, p. 709), it rivals in the certainty of its effect the best preparations of ergot. It would seem that it is a universal muscle poison, primarily stimulant in its action, and that in this way it affects the heart, the arterioles, and the uterus. According to von Bunge, it markedly increases peristalsis, so that even the intestines do not escape its muscular action.

Hydrastinine was originally recommended by Falck in the treatment of *menorrhagia, metrorrhagia, dysmenorrhea*, and even *endometritis.* The testimony as to its value in all forms of uterine hemorrhage seems to be conclusive, and it is affirmed by many gynæcologists that it has a pronounced alterative influence upon the mucous membrane of the uterus. From our own experience we are convinced that it has value as a cardiac tonic, not equal in power or certainty of action to digitalis, but often useful as a substitute for that drug, especially in minor cases of heart failure. Its sedative action on the central nervous system, conjoined with its stimulating influence upon the circulation and its pronounced effects upon the genital system, make it a very valuable remedy in the treatment of feeble women of hysterical temperament, with tendency to uterine fluxes.

Dose, usually employed, from three-fourths of a grain to one and a half grains (0.048–0.096 Gm.) every three to six hours, but probably larger doses might often be used with advantage, since no ill effects have been as yet recorded as being produced by it. The salt may be given hypodermically.

Hydrogen Ion Concentration.—The transformation of electrical into chemical energy is illustrated by the phenomena of *electrolysis.* An electric current passed through certain substances, capable of conducting a current of electricity, called *electrolytes,* which are in a state of fusion or solution, causes dissociation of the compound, and electropositive elements or groups (*ions*) are liberated at the negative electrode or cathode, while electronegative elements or groups are set free at the positive electrode or anode. The negative elements or groups are known as *anions* while the positive elements or groups are called *cations.*

Even when a current of electricity does not pass through a solution of an electrolyte a certain amount of dissociation takes place which is frequently in inverse proportion to the dilution. Thus strong sulphuric acid undergoes very little dissociation and is almost devoid of chemical action upon pure iron while a dilution with about ten volumes of water brings about a marked dissociation with an intensifying of the reaction upon iron. Sometimes the elements or groups set free undergo secondary changes through reaction with the solvent which is usually water. Why certain solvents such as water should favor the ionic dissociation is not thoroughly understood.

Ionic dissociation as applied to acids and alkalies may be interpreted as an intensity factor rather than a concentration factor. This factor is capable of being measured either by electrical or colorimetric methods. The former method being first employed, the symbol pH was adopted for this factor, signifying "Hydrogen Potential." The expression of this factor as applied to acids or alkalies is expressed in H ions on the acid side of neutrality and in OH ions on the alkaline side. The following table gives the pH values in whole numbers, in the first column, the equivalent in H ions and OH ions per given volume of the solvent in the second column and the equivalence in normality of acid and alkali respectively in the third column. (See also Clark's *Determination of Hydrogen Ions* for complete details of this important subject.)

ACID RANGE

pH* value	1 Gm. H ions in	Equivalent in acid volumetric solution
0.0	1 Liter	Normal acid
1.0	10 "	0.1 Normal acid V.S.
2.0	100 "	0.01 " " "
6.0	1,000,000 "	0.000001 " " "
7.0	10,000,000 "	Perfect Neutrality

ALKALINE RANGE

pH* value	17 Gm. (OH) ions in	Equivalent in alkaline volumetric solution
8.0	1,000,000 Liters	0.000001 Normal Alkali V.S.
9.0	100,000 "	0.00001 " " "
13.0	10 "	0.1 " " "
14.0	1 "	Normal Alkali

*The pH figure is the logarithm of the reciprocal of the H ion concentration expressed in relation to a certain volume of the solvent. The pH of neutral water is 7, since water contains 0.0000001 Gm. of hydrogen per liter, or 10^{-7}.

The measurement by means of an electrical apparatus is much more accurate than the colorimetric method, but the apparatus is quite costly and requires technical knowledge and skill to use. A hydrogen electrode consisting of one of the noble metals such as platinum, coated with platinum black, or an electrode of mercury coated with calomel will serve. A potentiometer is needed to measure the electromotive force.

The colorimetric method of determining hydrogen ion concentration is much more frequently employed. It takes advantage of the fact that certain indicators have a range of color change which is directly indicative in each case of a certain limited range of hydrogen ion concentration (acidity or alkalinity) and by carefully selecting a number of these indicators whose values have been carefully studied and checked by the potentiometer method almost the entire range may be covered. The indicators given in Clark's list are as follows:

The following list has been compiled from those given by Clark and by F. X. Moerk (*Proc. Pa. Ph. A.*, 1924):

Indicator	pH Range
Thymol Blue	1.2–2.8
Methyl Orange	2.9–4.0
Bromphenol Blue	3.0–4.6
Tetrabromphthalein	3.0–5.0
Methyl Red	4.4–6.0
Bromcresol Purple	5.4–7.0
Bromthymol Blue	6.0–7.6
Phenol Red	6.6–8.2

Indicator	pH Range
Phenolsulphonphthalein	6.8– 8.4
Alphanaphtholphthalein	7.0– 9.0
Cresol Red	7.2– 8.8
Orthocresolphthalein	8.0–10.0
Thymol Blue	8.2– 9.8
Tetranitrophthalein	9.0–10.0
Thymolphthalein	10.0–11.0
Sodium Indigodisulphonate	12.0–14.0

Slightly different values are given by some authorities for a few of the indicators in both of these lists. The use of these indicators require the use of certain buffer solutions or stabilizers, and for the intelligent application of this method of determining pH values either the details as described in Clark's book must be accurately followed, or one of the ready to use "Hydrogen Ion Testing Sets" which are now available may be employed.

The practical applications of the determination of pH value are increasing rapidly. Culture media are now brought to a very fine degree of uniformity. The action of germicides and disinfectants has been developed along more scientific lines. The fermentation and baking industries have been benefited. The determination of the pH value of the blood has thrown new light upon certain diseases. Soil productiveness and plant growth have been found to depend upon certain narrow limits in this connection. The action of enzymes is more intelligently controlled. These are a few of the more important fields when a knowledge of pH values has been of service.

Hydrogen Sulphide. *Hydrosulphuric acid. Sulphuretted Hydrogen.* H_2S.—A colorless gas of unpleasant odor, soluble in water, to which it imparts an acid reaction. 3.23 volumes of gas are absorbed by one volume of water at 15° C. Also soluble in alcohol. Has been liquefied at ordinary temperatures under a pressure of 17 atmospheres, or at ordinary pressures by a cold of −74° C., and at −85° C. becomes an ice-like solid. *Liquefied hydrogen sulphide* is a colorless, transparent, very mobile fluid with strong solvent properties. (*Chem. Ztg.*, 1904, No. 70.)

The symptoms of poisoning by hydrogen sulphide vary with the amount taken. Its inhalation in a concentrated form is followed by giddiness, nausea, excessive weakness, and rapid or immediate loss of consciousness. The very diluted gas produces nausea, pain in the head, and great general weakness; followed, if sufficient be taken, by coma, or stupor with delirium, and in some cases by general convulsions. The blood becomes of a brownish-black color, and after death remains fluid. The general appearances at the autopsy are not to be distinguished from those produced by the absorption of carbon dioxide, but the diagnosis is readily made by the odor which pervades the whole corpse.

Bruère (*J. A. P.*, Oct., 1891) showed that hydrogen sulphide formed with hemoglobin a greenish-brown compound, *sulphmethemoglobin* or *sulphemoglobin,* and it has been shown by Paul Binet (*Rev. Méd. de la Suisse Rom.*, xvi, 1896) that this sulpho-methemoglobin is produced in the blood during life, especially when the gas is in very large amount. It is worthy of remark that Bruère found *hydrogen selenide* and *hydrogen telluride* to act the same as the hydrogen sulphide.

In 1886 Bergeon proposed to the French Academy a method of treating *tuberculosis* by injecting hydrogen sulphide, diluted with pure carbon dioxide, into the large intestine, but the method has fallen into desuetude. Hydrogen sulphide is, however, a useful remedy in *pulmonary catarrh,* chronic or acute, as well as in *chronic rheumatism* and in *gout.* It is for this reason that sulphur springs are so frequently resorted to. Sulphuretted natural waters must be taken at the spring as they quickly decompose after issuing from the ground. Water saturated with hydrogen sulphide and carbon dioxide is usually not objected to by patients after the first day or two of its taking, and does not disagree with the stomach. *Dose,* from two to four fluidounces (60–120 cc.) three or four times a day.

Hydroquinone. *Hydrochinone. Quinol. Paradioxybenzene.* 1–4 $C_6H_4(OH)_2$.—This is one of the three isomeric diatomic phenols, of which resorcin is the meta variety. It was first prepared by the dry distillation of quinic acid, but is now made from quinone by reduction with sulphurous acid, the quinone being made by oxidizing aniline with dichromate mixture ($K_2Cr_2O_7 + H_2SO_4$). It is in shining white leaflets melting at 169° C., soluble in water, alcohol, and ether, and is used largely in photography as a developing agent. In 1877 Brieger found that *hydroquinone* produces in man giddiness, tinnitus aurium, and a lessening of the force and frequency of the pulse. The experiments of P. J. Martin have shown that in the frog hydroquinone causes violent convulsions, followed by paralysis. In the mammal small doses produce a rise in the arterial pressure, followed by a depression; both of these phenomena are apparently the result of an action of the drug upon the arterial vaso-motor system, although it is probable, from the experiments of Beyer, that the toxic dose of hydroquinone paralyzes both the heart muscle and the muscle fibers in the coat of the arterioles. The bodily temperature is lowered by large doses of hydroquinone, and, according to the experiments of Martin, this is chiefly due to an increase of heat dissipation and is, therefore, probably the result of a vasomotor paralysis.

Hydroquinone is also antiseptic, but inferior in power to phenol. The influence of hydroquinone upon the human being has been especially studied by Silvestrini and Picchini, and by Gaetano Traversa. (*France Méd.*, May, 1890.) According to these authorities, it is a prompt antipyretic, producing depression of temperature in *fever,* the reduction beginning in half an hour, and reaching its maximum in an hour and a half. Usually the antipyretic action is not accompanied by disagreeable symptoms, although after the larger dose excessive sweating chills, and some nervous disturbances have been noted. Hydroquinone has been used in *infectious fevers,* and in *acute articular rheumatism;* also as a gastro-intestinal disinfectant. *Dose,* three to eleven grains (0.2–0.71 Gm.).

Hydroxylamine Hydrochloride. $NH_2.OH.HCl$.—The free base is known only in solution, and is unstable. The crystalline hydrochloride forms colorless hygroscopic crystals similar to ammonium chloride in appearance, soluble in an equal weight of water, also in glycerin and in fifteen parts of alcohol. In 1888 Binz found that this substance caused in the lower animals stupor, convulsions, and a destruction of the red blood corpuscles, of such character that their hemoglobin was reduced to methemoglobin or even to hematin. In 1899 L. Lewin of Berlin, further investigated the subject, confirming in part the results obtained by Binz, and showing that the poison acts both upon the dead and living blood, and that its action upon the corpuscle is probably due to its decomposition, and the liberation of nitric or nitrous acid. In 1889 John Fabry (*Arch. de Derm. et de Sph.*, tome ii, 1889) found that a 10 per cent. solution is exceedingly irritating to most human skins, producing intense redness, violent burning, sweating, and not rarely vesication. Some skins will not bear a 1 per cent. solution, so that it is not safe in any new case to use a solution stronger than this. The substance was employed by Fabry, and since then by other clinicians, as an agent to replace pyrogallol and chrysarobin in the treatment of skin diseases, offering at the same time the advantage of being colorless, and not staining the skin, linen, etc. It has been used in *chronic psoriasis,* in *scabies,* in *lupus, herpes tonsurans, parasitic sycosis,* etc., with asserted excellent results, though Groddeck condemns it as being too irritating and liable to produce constitutional symptoms, and inferior in its healing powers to chrysarobin and pyrogallol. The solution of *hydroxylamine hydrochloride* may be prepared with alcohol or water, but should always be rubbed up with prepared chalk to neutralize any excess of acid.

Hydroxylamine Sulphate. *Oxy-ammonium Sulphate.* $(NH_2OH).H_2SO_4$.—It has been suggested by Bang (*B. K. W.,* 1907, p. 216) for the quantitative estimation of sugar in the urine with Fehling's solution. The method consists in boiling definite quantities of the urine to be tested with an excess of the copper solution, and then determining the amount of hydroxylamine necessary to decolorize the copper. It is also used as a reducing agent in the quantitative determination of chlorates, bromates and iodates. (Schimpf, *Volumetric Analysis,* 5th edition.)

Hygrophila. *Br. Add.* 1900.—The dried herb including the root of *Hygrophila spinosa* T. And. (*Asteracantha longifolia* Nees). (Fam. *Acanthaceæ.*) This species of *hygrophila* has long been used in India as a diuretic in the treatment of *dropsies,* especially where there is hepatic obstruction, and also as a popular *aphrodisiac.* In Southern India the root is an article of commerce, but in Bombay the seeds are commonly employed. By means of petroleum benzin C. H. Warden obtained from the roots a crystalline principle (*Phg. Ind.,* vol. 3). The *decoction of hygrophila* (*Decoctum hygrophilæ,* Br. Add., 1900), two ounces of the root with three pints of water boiled to a pint, is given in *doses* of one-half to two fluidounces (15–60 cc.).

The seeds of the *H. salicifolia* of Java are called by the natives "Telor kodok" (that is, frog's eggs), from their peculiar property of forming a gelatinous shiny mass when added to water. They are used for the preparation of poultices (Leudner, *Ph. Era,* 1918, ii, 181).

Hypericum. *Hypericum perforatum* L. *St. John's Wort. Millepertuis, Casse-diable,* Fr. *Johanniskraut, Harthen,* G. (Fam. *Hypericaceæ.*)—A perennial herb, with a very acrid juice, 1 to 2 ft. in height, with 2-edged stems, opposite, sessile, oblong to linear, obtuse, black-dotted leaves, bright yellow flowers arranged in terminal cymes and ovoid, capsular fruits. It is indigenous to Europe but naturalized in fields in the United States. It has a peculiar balsamic odor, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow color to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and coloring matter. This latter, known as *hypericum red,* is a reddish resin, smelling like the flowers, soluble in alcohol, ether, ethereal and hot fatty oils, coloring the solution from wine red to blood red. It is soluble in alkalies with green color, and gives yellow precipitates with the alkaline earths and metallic salts. As a medicine it was in high repute among the ancients in an extraordinary variety of complaints but it was, perhaps, most highly esteemed as a remedy in *wounds* and *bruises,* for which it was employed both internally and externally. It probably has somewhat analogous power to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs, and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the *dose* of two drachms or more. A preparation, *oleum hyperici* or *red oil,* made by macerating four ounces of the tops in a pint of olive oil, is still used as a home remedy for *bruises.*

Hypnal.—*Chlorpyrine. Chloralhydrate antipyrine,* $C_{11}H_{12}N_2O.CCl_3.CH.(OH)_2$, results by rubbing together 188 parts of antipyrine and 165.5 parts of hydrated chloral and crystallizing out the product. It forms colorless crystals melting at 67° C. It is supposed to combine the somnifacient action of chloral with the anodyne effect of antipyrine, and is used not only in the treatment of *insomnias* of nervous origin, but also in those caused by pain. The *dose* is from fifteen to thirty grains (1.0–2.0 Gm.).

Hypnone.—*Phenyl-methyl-ketone. Benzoylmethide. Acetophenone,* $C_6H_5.CO.CH_3$, is obtained by the dry distillation of a mixture of calcium acetate and calcium benzoate; colorless or yellow liquid of oily consistency, boiling at 198° C. It has a pleasant odor suggesting that of orange flowers. It has been used as a somnifacient. *Dose,* three to eight minims (0.2–0.5 cc.).

Hyssopus. *Hyssopus officinalis* L. (Fam. *Labiatæ*) *Hyssop. Hysope,* Fr. *Isop, Ysop,* G.—Hyssop is a perennial herb indigenous to Europe but naturalized in the U. S., occurring in gardens and along roadsides. The flowering summits and leaves have been used in medicine. They have an agreeable aromatic odor, and a warm, pungent, bitterish taste, due to the presence of a volatile oil. This oil is colorless or greenish-yellow, of peculiar odor, sharp camphor-like taste, and neutral reaction. It has a sp. gr. from 0.88 to 0.98, distils between 142° and 162° C., and is soluble in its own bulk of alcohol of 0.85 sp. gr. The acid found in the oil has been identified as *l-pinonic acid,* and the ketone *l-pinocamphene.* Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants.

Iatrevin.—This is a condensation product of menthol and isobutyl-phenol. It is a clear fluid of an aromatic odor, miscible with alcohol in all proportions. It has been used by Munter (*Med. Klin.,* 1906, p. 1097) as an internal antiseptic in the treatment of *pulmonary tuberculosis.* His conclusions, as far as we know, have not been confirmed.

Iberis. *Iberis amara* L. (Fam. *Cruciferæ*) *Bitter Candytuft.*—A small European bitter, annual herb with alternate, lanceolate leaves, white flowers and orbicular fruits. The leaves, stem, and root are said to possess medicinal properties, but the seeds are more efficacious. The plant appears to have been employed by the ancients in *rheumatism, gout,* and other diseases. In large doses it is said to produce giddiness, nausea, and diarrhea, and to be useful in *cardiac hypertrophy, asthma,* and *bronchitis,* in *doses* of from one to three grains (0.065–0.2 Gm.) of the seed.

Ibogaine. $(C_{52}H_{66}O_2N_6)$.—This alkaloid was separated by Dybouski and Landrim (*Nouv. Rem.,*

1905) from the roots of the *Tabernanthe Iboga*, a plant found in the Congo. In overdose it causes hallucination and general paralysis, with death due to failure of the respiratory muscles. In *dose* of one-third to one-half grain it is said to act as a stimulant to the nervous system somewhat similar to caffeine. Haller and Heckel (*C. R. A. S.*, 1901, cxxxiii) have found another alkaloid, ibogine, in the same plant.

Ichthoform.—This is said to be obtained by the action of formaldehyde upon the products of sulphonization of ichthyol hydrocarbons, and to be superior to iodoform as an antiseptic. Externally it has been used by Unna, and in skin diseases is superior to the ordinary formaldehyde preparations. He asserts that it softens rather than hardens the skin. It has also been employed as an intestinal antiseptic in *doses* of fifteen to thirty grains (1–2 Gm.) three to four times a day.

Ichthyocolla. *U. S.* 1890. *Isinglass. Colla Piscium*, P. G. *Fish-glue. Ichthyocolle, Colle de Poisson*, Fr. *Hausenblase, Fischleim*, G. *Colla di Pesce*, It. *Colla de Pescado*, Sp.—Isinglass is a gelatinous substance prepared from the sounds or swimming bladders of many species of fish in various parts of the world. The best known variety is chiefly procured from the Volga and other streams of Southern Russia. It is prepared from several species of sturgeon including the *Acipenser Huso* L., or *beluga*, the *A. ruthenus* L., or *sterlet*, the *A. Sturio* L, or common *sturgeon*, and the *A. stellatus* Pallas or *starred sturgeon*. The air bags, having been split open, cleansed, and dried, are known in commerce by the name of *staple isinglass*, which is divided into the *long* and the *short staple*. Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass*. The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties, the long staple and the finest book isinglass are the best. That in cakes is brownish, of an unpleasant odor, and employed only in the arts. Inferior kinds, with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish. An inferior Russian product, known in English commerce by the name of *Samovey isinglass*, is procured, according to Pereira, from the *Silurius glanis* L. It comes, like the better kind, in the shape of leaf, book, and the short staple. Isinglass, little inferior to the Russian, is made in Iceland from the sounds of the cod and ling. It is said also to be prepared by the fishermen of Newfoundland. We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering, and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence. The *Brazilian isinglass* is inferior to the Russian. Considerable quantities of isinglass are manufactured in New York and New England from the sounds of the *hake* (*Gadus merluccius*) and of the weak-fish (*Otolithus regalis*). This *American isinglass* is in thin ribbons 6 dm. in length, and from 2.5 to 6 cm. in width. It has a fishy taste and odor, which render it unfit for culinary or medicinal purposes. The sounds are dried whole, or merely split open, and vary much in size and texture, weighing from a drachm to an ounce. An article called *refined* or *transparent isinglass* is made by dissolving the New England isinglass in hot water, and spreading the solution to dry on oiled muslin. It is in very thin, transparent plates, and is an excellent glue, but retains a strong fishy odor. In India and China the swimming bladders of various species of fish furnish the so-called Indian and Chinese isinglass. At the present writing the various forms of isinglass are comparatively little used, their place being supplied by various brands of gelatin produced from fresh bones. (See *Gelatinum*, p. 509.)

In its purest form it is "in separate sheets, sometimes rolled, of a horny or pearly appearance; whitish or yellowish, semitransparent, iridescent, inodorous, insipid; almost entirely soluble in boiling water and in boiling diluted alcohol. A solution of isinglass in 24 parts of boiling water forms, on cooling, a transparent jelly." *U. S.* 1890. The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of impurities, amounting, according to Hatchet, to less than 2 per cent. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is composed of *collagen* which on boiling hydrolizes to gelatin. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by alkaline solutions. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with sulphuric acid, it is converted into a peculiar substance, called *glycocoll* or *sugar gelatin*, which is in reality *amidoacetic acid*, $CH_2.NH_2.COOH$. Its aqueous solution speedily putrefies. An ingenious adulteration has been practised by rolling a layer of gelatin between two layers of genuine isinglass. This may be detected by the disagreeable odor and taste of the adulterated drug, and the effects of water upon it. Genuine isinglass, cut into shreds and treated with water, becomes opalescent and more opaque than before; while the shreds, though they soften and swell, remain unbroken, and when examined by the microscope are seen to be decidedly fibrous. Gelatin, on the contrary, when similarly treated, becomes more transparent than before; the shreds are disintegrated, and the structure appears amorphous under the microscope. In the adulterated article both these characters are presented in layers more or less distinct. (*P. J.*, ix, 505.) Moreover, Redwood and Letheby observed that the ash of true isinglass does not exceed 0.9 per cent., while glue contains from 2 to 4 per cent. of ash. An adulterated isinglass would therefore yield more ash than the normal. A *false isinglass* has been imported into England from Para, in Brazil, consisting of the dried ovary of a large fish. It has somewhat the form of a bunch of grapes, consisting of ovoid or roundish masses attached by a footstalk to a central axis. It is not gelatinous, and is unfit for the purposes to which isinglass is applied. (*A. J. P.*, xxv, 144.) For table showing value of different kinds of European isinglass, see *P. J.*, 1884, p. 900.

Isinglass has been strongly recommended by Wm. T. Wenzell instead of hide powder in the estimation of tannin. (*A. J. P.*, 1894, 447.)

Isinglass plaster or *court plaster* (*Emplastrum Ichthyocollæ*, U. S., 1890), a very popular adhesive for closing small wounds, may be made as follows: "Isinglass, *ten grammes;* Alcohol, *forty grammes;* Glycerin, *one gramme;* Water, Tincture of Benzoin, each, *a sufficient quantity.* Dissolve the Isinglass in a sufficient quantity of hot Water to make the solution weigh *one hundred and twenty grammes.* Spread one-half of this, in successive layers, upon taffeta (stretched on a frame), by means of a brush, waiting after each application until the layer is dry. Mix the second half of the Isinglass solution with the Alcohol and Glycerin, and apply it in the same manner. Then reverse the taffeta, coat it on the back with Tincture of Benzoin, and allow it to become perfectly dry. Cut the plaster in pieces of suitable length, and preserve them in well-closed vessels. The above-directed quantities are sufficient to cover a piece of taffeta *thirty-eight centimeters* square." *U. S.*, 1890.

Ichthyol Substitutes.—There have been placed on the market a large number of compounds intended for the same uses as ammonium sulphichthyolate (See Part I). Among these may be mentioned in addition to those described below, *ichtammon, ichthium, ichtolithum, ichden, ichthyopon, isarol, petrosulpho, piscarol, pisciol, subitol, petrosulfol, sulfogenol, thilaven, thiolin, thiozin,* etc. Beckurts and Freerichs (*J. A. Ph. A.*, 1913, ii, p. 335) finds that there is great difference in the chemical composition of these various preparations.

Ammonium Ichthynatum, N. N. R. 1924.—This is an aqueous solution of sulphonated ammonium compounds resulting from the action of sulphur upon distillates from certain bituminous shales. It is a dark brown, syrupy liquid with a characteristic odor and a burning taste. It is completely soluble in water, partially soluble in alcohol and miscible with glycerin in all proportions. Its aqueous solution is slightly acid to litmus. It is incompatible with acids, carbonates and hydroxides, alkaloids and mercuric chloride. It is used internally in doses of 5 to 15 minims (0.3 to 1 cc.) and locally in varying strengths ranging from 3 to 40 per cent.

Hirathiol, N. N. R. 1924.—This synthetic compound is manufactured in Japan and is an aqueous solution containing sulphones, sulphonates and sulphides in combination with ammonium. It is a brownish-black, syrupy liquid with a characteristic empyreumatic odor, soluble in water, glycerin and alcohol and miscible with fats. The aqueous solution is faintly acid to litmus.

Isarol. Ichthyodin.—This is a proprietary form of ammonium sulphichthyolate of Swiss origin. It occurs as a brownish-red thick liquid, having an odor like that of ichthyol; containing about 9 per cent. or, when dried, 17 to 19 per cent. of sulphur of which 5 to 7 per cent. is in the "sulphidic" form. It makes a clear solution in water, and is also soluble in ten parts of 95 per cent. alcohol.

Saurol.—An oily substance obtained by the distillation of bituminous rock in Switzerland. It contains from 6 to 7 per cent. of sulphur in organic combination.

Thigenol.—This is prepared by dissolving sulphur in boiling glyceride of oleic acid and subsequent treatment with sodium hydroxide whereby is formed sodium sulpho oleate, and evaporating the solution *in vacuo* to a specific gravity of 1.05. Thigenol is a dark brown liquid freely soluble in water, dilute alcohol and glycerin. With hard water it throws down a precipitate.

Thigenol is asserted to possess the local therapeutic virtues of sulphur and is used chiefly in the treatment of *skin diseases* in the form of a 20 per cent. ointment. It is occasionally prescribed internally in *doses* of 3 to 10 grains (0.2 to 0.6 Gm.).

Thiol.—This is a thin, dark-brown, neutral liquid, with an odor somewhat like that of Russia leather, having a specific gravity of from 1.082 to 1.089; its aqueous solution is transparent, froths when shaken, and is not precipitated by strong alcohol; it is also feebly soluble in glycerin. On evaporation, liquid thiol yields about 40 per cent. of dried thiol. It is prepared from paraffin oils of from 0.89 to 0.90 sp. gr., which are treated with sulphur at high temperatures. The unsaturated hydrocarbons (olefins, etc.) are alone attacked, and these are then extracted by suitable solvents from the saturated hydrocarbons. They are then acted upon by concentrated sulphuric acid at low temperatures, and the thiol separated out by the addition of ice. It may then be evaporated *in vacuo* to either *thiolum liquidum* or *thiolum siccum.*

It is asserted that thiol possesses the remedial properties of ichthyol, to which it is superior on account of its being odorless. It has been used in the treatment of superficial and deep inflammations, as in *eczema* and *syphilitic ulcers* and in various joint conditions as *sprains, rheumatism* and the like. Kretzomer states that painted along the nerve in cases of *acute sciatica,* it produces immediate relief. (*All. M. C. Z.*, 1909.)

The liquid is used in the form of a solution or ointment; the dried thiol is sometimes employed as a powder. In *rheumatism* thiol has been given internally in *doses* of from five to ten minims (0.3–0.6 cc.), or the dried preparation in *doses* of from one to two grains (0.065–0.13 Gm.).

Tumenol.—A dark brown or brownish-black liquid, of a syrupy consistence, which is made from bituminous shale oils. These are agitated with sodium hydroxide solution to remove phenols and then with sulphuric acid to remove pyridine and other bases. The oil is then treated with fuming sulphuric acid. The dark syrupy liquid which separates is washed with water and dissolved in sodium hydroxide. From this solution ether extracts *tumenol oil.* Hydrochloric acid, on the other hand, if added to the sodium hydroxide solution, throws down *tumenol-sulphonic acid.* A mixture of these two substances constitutes *tumenol venale,* a soft, resinous, odorless mass. A. Neisser (*D. M. W.*, 1891) highly commends tumenol as a local application in *eczema* and as having extraordinary powers over the itching of *prurigo, parasitic dermatitis* and other *skin affections.* He uses a lotion made with equal parts of ether, rectified spirit and water or glycerin and 10 per cent. of tumenol.

Ichthyol Albuminate. *Ichthalbin.*—This is a greenish-brown powder, insoluble in water and acid solutions, soluble in alkaline solutions, odorless, almost tasteless. It is prepared by precipitating *egg albumin* with ichthyol and prolonged washing of the precipitate until the ichthyol odor and taste are removed. It is stated to contain about 75 per cent. of ichthyol. It is not toxic, and when given internally, even in large doses, produces little or no irritation of the gastro-intestinal tract. It is affirmed that as an internal remedy it is practically the same as ichthyol, and as such is useful in various conditions connected with wide-spread vascular dilatation, in *syphilis*, in *struma*, and in other states of lowered nutrition. It has also been used in the treatment of various inflammatory conditions of the intestinal tract, especially in chronic *colitis* and *enteritis*. *Dose*, from fifteen to thirty grains (1–2 Gm.) three times a day, best taken in capsules; or in the case of young children it should be mixed with chocolate.

Ilex. *Holly.* *Houx*, Fr. *Stechpalme, Christdorn*, G.—Several species of *Ilex* (Fam. *Aquifoliaceæ*) are employed in different parts of the world. *I. Aquifolium* L., or *European Holly*, is an evergreen tree growing to the height of 40 feet, but under cultivation is often shrubby. It has a pyramidal crown of short spreading branches which bear alternate, ovate or oblong-ovate, sinuate, spiny toothed, shining coriaceous leaves and globular, scarlet fruits. It is the most beautiful of all evergreens, but is unsuited to our climate, being too tender to withstand the winters in the northern States and equally affected by the hot, dry summers in the southern States. A viscid substance called *birdlime* is prepared from the inner bark (see *Viscum*). The leaves, which are of a bitter, somewhat acrid taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in *catarrh, pleurisy, small-pox, gout*, etc. At one time they enjoyed a brief reputation in France as a cure for *intermittents.* They were used in powder, in the *dose* of a drachm two hours before the paroxysm, and this dose was sometimes repeated frequently during the apyrexia. Labourdais obtained an amorphous bitter principle which he called *ilicin* from the leaves. (See *A. J. P.*, xxi, 89.) Moldenhauer in 1857 separated a yellow coloring substance called *ilixanthin*, and a peculiar acid called *ilicic acid. Ilicic alcohol*, $C_{30}H_{50}O$, was separated by Personne from birdlime and found to be identical with α-amyrin. (*C. R. S. B.*, 1908, 862.) Ilixanthin is $C_{17}H_{22}O_{11}$. It crystallizes in yellow needles, which change color at 185° C., melt at 198° C., and at 214° C. boil with decomposition, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes excite vomiting. Their expressed juice has been used in *jaundice.*

Ilex opaca Ait., or *American holly*, is a middling evergreen tree attaining a height of 50 feet, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It resembles European holly in many details but has less glossy leaves and fruits. The berries, examined by D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassium, calcium, and magnesium. One of the crystallizable principles was inodorous and tasteless, the other inodorous but intensely bitter. The latter is probably pure *ilicin.* (*A. J. P.*, xxviii, 314.) Walter A. Smith (*A. J. P.*, 1887, 1668) obtained a resin soluble in alcohol by the ether extraction, and in the portion of this soluble in water he obtained evidences of a glucoside. This species is said to possess the same medicinal properties as *I. aquifolium* L.

Ilex paraguayensis St. Hil. (*I. Maté* St. Hilaire) yields the celebrated *Paraguay tea*, or *Maté*, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along streams in Paraguay, Brazil and other South American countries, and also cultivated for the sake of its leaves, which are the part used. They vary in outline from obovate, obovate-oblong to elliptic-oblong, possess an obtuse or obtusely acuminate apex, tapering base and crenate-serrate margin and are short-petioled. These are stripped from each plant every two or three years. The period of their collection extends from December to August, sometimes beginning earlier but never continuing later. Companies are formed who penetrate far into the forest at a distance from the settlements, and devote a long time to the collection and preparation of the leaves. These are first dried by exposure to heat, and are then reduced to powder more or less fine, which is kept for several months protected from moisture, and then packed in sacks and delivered to commerce. (See *Ph. Rec.*, 1891.) They have a balsamic odor and bitter taste, and are usually at first disagreeable to the palate. They have a pleasant and corroborant effect upon the stomach, but, when largely taken, cause purging and vomiting. They are used in the form of infusion, which is prepared from the entire leaves as we prepare tea; or, under the name of *cha maté*, a fine powder is put in a cup of hot water by the drinker, and after a moment's stirring, the fluid is sucked up by means of a tube expanded below, and pierced with fine holes, so as to strain out the powder. They contain, besides other substances, a peculiar tannin and the alkaloid caffeine in variable amount. Some fresh leaves of *Ilex paraguayensis* grown in the Cambridge Botanical Gardens were found by A. H. Allen, after drying, to contain 15.6 per cent. of tannin and 1.13 per cent. of caffeine. (*Com. Org. Anal.*, 2d ed., iii, Part II, 527.) The consumption of *maté*, or *yerba*, in South America is enormous. Although largely produced in the Argentine Republic, tons are annually shipped to countries in South America.

Ilex vomitoria Ait. (*I. Cassine* Walt.) is a handsome evergreen shrub or small tree growing in our Southern States, and especially abundant along the southern coast of Florida. It possesses oval, oblong or elliptic glossy leaves, deep green on upper surface and pale green beneath. These are obtuse at the apex and crenate-serrate along the margin. Those of the upper branches are 1 to 2.5 cm. long while those on the lower branches are frequently larger and oblong-lanceolate in outline. The flowers are small and white and occur in axillary clusters on branches of the previous year. The fruit is a red globose drupe which usually contains 4 nutlets. This species has often been confused with *Ilex Cassine* L. which differs from it in having larger leaves and acute calyx teeth. The calyx teeth of *I. vomitoria* are obtuse. Analysis of its leaves by Venable (*A. J. P.*, 1885, 390) gave 7.39 per cent. of tannic acid and 0.27 per cent. of caffeine. Smith (*A. J. P.*, xliv, 217) found 0.011 per cent. of volatile oil and 0.122 per cent. of caffeine. It is the *Cassena* or *Yaupon* of the North Carolina and Florida Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* Walt. (*I. Cassine* L.) or *Dahoon holly*, have similar properties, and are also said to have entered into the composition of the black drink.

Illicium. *U. S.* 1890. *Star-Anise. Chinese Star Anise. Fructus Anisi Stellati. Semen Badiani. Sternanis*, G. *Badine*, Fr.—"The fruit of *Illicium verum* Hooker filius (Fam. *Magnoliaceæ*)" *U. S.*, 1890. Of the genus *Illicium*, seven species are recognized, of which two are found on the Atlantic coast of southern North America, two in Hindostan, and three in China and Japan. Many of the species are possessed of aromatic properties.

The plant yielding star-anise is indigenous to Southeastern Asia and extensively cultivated in subtropical countries. It is an evergreen tree with entire, elliptic to oblanceolate, glandular-punctate leaves and greenish-yellow axillary flowers each with about 10 petals. The fruit which is chiefly used in the manufacture of oil of anise consists of usually 8 boat-shaped follicles or carpels arranged around a central axis. The carpels have an acute summit and taper to a nearly straight beak; externally, they are reddish-brown and somewhat wrinkled; the inner surface is smooth and shiny and encloses a single, smooth, compressed ovoid, brown seed. The odor and taste is aromatic, resembling anise, and this serves to distinguish them from the fruits of the Japanese star-anise which are also known as "*Shikimmi fruits*" or "*Skimmi fruits.*" The latter have an odor resembling Cajuput or Sassafras and are obtained from *Illicium religiosum* Sieb. et Zucc., a tree which is extensively cultivated in the groves of the Buddhist Temples in Japan.

I. religiosum Sieb. *et Zucc.* of India, is very poisonous, causing vomiting and epileptiform convulsions, with dilated pupil and exceedingly cyanosed countenance (see Guerrero, *Philippine J. of Sci.*, 1916, xi, 203); in it has been found by J. F. Eykman (*P. J.*, xi, 1046) a crystalline principle, for which the name of *shikimine* or *sikimin* has been proposed. Its seeds are sometimes sold for those of star-anise with baneful results.

Eykman (*P. J.*, 1885, p. 985) has shown that in the essential oil of the fruit of *Illicium religiosum*, safrol is found, accompanied by eugenol. On the other hand, the chief constituent of the oil of *I. verum* is anethol. See table by Eykman showing constituents of oil of *Illicium religiosum* compared with those from allied oils in *U. S. D.*, 19th ed., p. 1526.

The fruits of star-anise are gathered from wild and cultivated plants. Most of the drug is used for the production of volatile oil. The commercial supplies come chiefly from China.

Star-anise was examined by C. E. Schlegel (*A. J. P.*, 1885, p. 426), who found a saponin in the aqueous extract; in the alcoholic extract, a crystalline principle of a strong musk-like odor, which did not show alkaloid or glucosidal reactions, and *oil of star-anise.*

I. floridanum Ell., *poison bay, sweet laurel*, a small evergreen tree or shrub with oblong-lanceolate, acuminate leaves, which grows westward from Florida along the coast bounding the Gulf of Mexico, has its bark, leaves, and probably also seed vessels endowed with a spicy odor and taste, analogous to those of anise. Another species, *I. parviflorum* Vent. (*I. anisatum* Bartr., not L.) a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavor closely resembling that of sassafras root. A decoction of the seeds is said to produce violent gastro-intestinal irritation, followed by motor and sensory paralysis, with convulsions and death if the dose has been sufficient. E. Barral (*Revue Gén. de Clin.*, Oct., 1889) states that he has obtained a poisonous glucoside from the kernel. H. C. C. Maisch (*A. J. P.*, 1885, 280) obtained from the leaves a crystalline alkaloid to which the bitter taste is due, tannin, and a resin. In the root bark and capsules he found volatile oil and a crystalline principle, melting at 100° C., insoluble in alcohol and ether, but soluble in chloroform, and neutral to test paper.

The constituents of low boiling-point in star-anise oil, consisting of terpenes essentially, have been reported upon by the chemists of Schimmel & Co. (*Schim. Rep.*, April, 1893.) They find dextro-pinene, boiling at 157° to 163° C., and lævophellandrene, boiling at from 170° to 175° C.

The medicinal properties of the oil of star-anise are similar to those of oil of anise. Sikimin is not used in medicine. It is violently poisonous, belonging to the group of convulsants of which picrotoxin is the type. (See Plugge and Schutte, *A. I. P. T.*, iv, 1897.)

Impatiens. *Impatiens biflora* Walt. and *I. pallida* Nutt. *Touch-me-not. Jewel-weed. Balsam-weed.*—These two species of *Impatiens* (Fam. *Balsaminaceæ*), the former of which is better known commonly as *Spotted Touch-me-not* and the latter as *Pale Touch-me-not*, are indigenous, annual, succulent plants growing in low, moist, shaded grounds, and flowering from July to September. They may be known by their tender, juicy, almost transparent stems; by their yellowish flowers, which in *I. pallida* are pale and sparingly punctate, and in *I. biflora* are orange-colored and spotted with reddish-brown and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of *I. nolitangere* L., of Europe and Asia, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. Ruan of Philadelphia, employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The fresh juice is reputed to be efficacious in the treatment of rhus poisoning. The *I. Balsamina* L., or *balsam-weed, touch-me-not*, etc., of the gardens resembles the other species in its effects.

Imperatoria. *Imperatoria Ostruthium* (L.) Kch. *Masterwort. Rhizoma Imperatoriæ*, P. G. *Impératoire*, Fr. *Meisterwurz, Kaiserwurz*, G.—An umbelliferous plant, indigenous in Southern Europe. The root has a strong odor, similar to that of angelica, and a pungent, aromatic taste, attended by a flow of saliva, and followed by a growing warmth which remains long in the mouth. A crystallizable, tasteless principle, called *imperatorin*, was extracted from the root by Wackenroder, and Gorup-Besanez found in the root another principle, to which he gave the name of *ostruthin*. Besides these two crystalline compounds, masterwort contains a volatile oil, composed of a hydrocarbon and an oxygenated compound, probably the aldehyde of angelic acid. (Wagner, *J. P. C.*, lxii, 283.) Jassoy (*Ap. Ztg.*, v, 150) has since investigated the substance ostruthin and gives it the formula $C_{18}H_{20}O_3$. He states that it does not contain a methoxyl group but a phenol-like hydroxyl. By the action of bromine in chloroform solution it is changed in the presence of acid sodium carbonate into *tribromostruthin*, $C_{18}H_{19}Br_3O_3$. (Schmidt, *Pharm. Chem.*, Bd. ii, 3te Auf., 1510.) Herzog subsequently examined the rhizomes and found a substance identical with oxy-peucedanin. (*A. Pharm.*, 1908, 414.) The root of masterwort was formerly used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium.* It is, however, merely a stimulant aromatic, which in this country is unknown as a remedy. Its leaves are used as a potherb and to flavor cheese.

Incassa Poison.—This is an African ordeal bark, which has been studied by Liebreich, who found in it a very violent cardiac poison.

Indian Red.—A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is *red ochre,* and owes its color to *ferric oxide.*

Indian Yellow.—This is a pigment manufactured from a yellow substance from India, called *purree.* Purree occurs in commerce in balls, from three to four ounces in weight, which are dark brown externally and deep orange within. It has a peculiar odor, closely resembling that of castor. This circumstance gave rise to the belief that it was of animal origin, but Stenhouse found it to consist of magnesia, united with a peculiar acid, which he names purreic (*euxanthic acid* of Erdmann), and which forms nearly one-half of the crude substance. *Purreic acid* is in small crystals of a light yellow color, dissolving sparingly in cold water, quite readily in boiling water, and abundantly in hot alcohol and ether. It has at first a sweetish and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberine. When acted upon by boiling nitric acid, it is finally converted into trinitroresorcinol, $C_6H(NO_2)_3(OH)_2$. Heated with diluted sulphuric acid (3 per cent.) to 140° C., it decomposes into *euxanthon* and *glycuronic anhydride.* The euxanthon is recognized as *dioxydiphenyleneketone oxide,*  $CO\langle{}^{C_6H_3(OH)}_{C_6H_3(OH)}\rangle O$, and has been made synthetically. Purreic or euxanthic acid is monobasic, and has the formula $C_{19}H_{16}O_{10} + 3H_2O$. Stenhouse concludes that purree is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence.

The term "Indian yellow" is sometimes applied to the *cobalt and potassium nitrite* and to an aniline derivative, *Azoflavin-Z,* which is a mixture of nitrated diphenylamine orange and nitrodiphenylamine. These should not be confused with the foregoing drug.

Indigo. *Indicum. Pigmentum Indicum. Indigo,* Fr., G.—This well-known and highly important dye-stuff is obtained from various species of *Indigofera* (Fam. *Leguminosæ*), especially *I. tinctoria* L. and *I. Anil* L., and is accorded also by other plants, such as *Wrightia tinctoria* R. Br. (Fam. *Apocynaceæ*), *Polygonum tinctorium* Ait. (Fam. *Polygonaceæ*), *Tephrosia tinctoria* Pers., *Galega tinctoria* L., and *Tephrosia Apollinea* Link. (Fam. *Leguminosæ*), etc. For an interesting account of the manufacture in Manchuria of indigo from *Polygonum chinense,* see *Am. Drug.*, Aug., 1888. It does not exist ready formed, but is generated, during fermentation, from another principle existing in the plant. This principle appears to have been isolated from *Isatis tinctoria* L. (Fam. *Cruciferæ*), by Ed. Schunck, who has named it *indican.* Through the agency of the mineral acids, it is resolved into indigo and sugar, and perhaps the same result may take place in fermentation. Indican is yellow, amorphous, of a nauseous bitter taste, with an acid reaction, and readily soluble in water, alcohol, and ether. In the process of preparing indigo, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish color, and in due time is decanted; the coloring principle dissolved by the water absorbs oxygen from the air, and assumes a blue color, becoming at the same time insoluble; a gradual precipitation takes place, favored by the addition of lime water or an alkaline solution, and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. It is of an intensely blue color, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the finger nail. Heated to 287.7° C., it emits a reddish-violet vapor, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by concentrated or fuming sulphuric acid, because of the formation of *monosulphindigotic* and *disulphindigotic acids,* of which the first is difficultly soluble in water and the second easily soluble. The sodium salt of this latter is the *indigo-carmine* of commerce (see below). Indigo is soluble in chloroform, aniline, oil of turpentine, paraffin, phenol, and benzene. By deoxidizing agents such as the acid sulphites, and in a less degree with sulphurous acid, it is deprived of its blue color, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Certain volatile oils have a reducing effect when boiled with tincture of indigo, as the oils of turpentine, peppermint, lavender, etc. The reduction and decolorization of indigo solutions by glucose is the basis of one of the most delicate qualitative tests for diabetic sugar in urine. Chlorine also destroys the blue color. For modes of testing the value of a specimen of indigo, see Sadtler's *Industrial Organic Chemistry,* 443. The most important of the methods for the determination of the indigo blue may be summarized under three heads,—viz., oxidation methods, reduction methods, and sublimation of the pure indigo blue from the commercial product. A table of analyses of commercial samples with results according to the several methods above referred to will be found in Allen, *Com. Org. Anal.*, 2d edition, iii, 311.

The artificial production of indigo was successfully solved by A. von Baeyer of Munich, who proposed several methods capable of commercial utilization. One method starts with cinnamic acid, $C_9H_8O_2$, made artificially from benzaldehyde, which is changed into *ortho-nitro-cinnamic acid,* $C_9H_7NO_4$, and this by the intervention of the di-bromine derivative into *ortho-nitro-phenylpropiolic acid,* $C_9H_5NO_4$, and this by the action of alkalies in the presence of reducing agents, like grape sugar or xanthogenates, is converted directly into *indigo blue* $(C_8H_5NO)_2$.

A second method was by the action of dilute alkalies upon a solution of *o-nitro-benzaldehyde* in acetone according to the reaction:

$$2C_6H_4(NO_2)CHO + 2C_3H_6O = C_{16}H_{10}O_2N_2 + 2C_2H_4O_2 + 2H_2O$$

A method of Heumann, also successfully carried out on a large scale, is to treat *phenylglycin,* $C_6H_5.NH.CH_2.COOH$, with alkalies, and then oxidize the resulting alkaline solution, when *indigotine,* $C_{16}H_{10}N_2O_2$, is formed. These methods were found to be to expensive, but it has finally been made commercially, and on a scale which is fast displacing natural indigo, by the following method. *Anthranilic acid,* $C_6H_4(NH_2)COOH$, (which can be prepared cheaply from naphthalene), combines with monochloracetic acid to form *phenyl-glycocollcarboxylic acid,* $C_6H_4\begin{matrix}\diagdown NH.CH_2COOH\\ \diagdown COOH\end{matrix}$, and this on fusion with caustic soda yields *indoxyl,* $C_6H_4\begin{matrix}\diagup NH \diagdown\\ \diagdown C(OH) \diagup\end{matrix} CH$, which, in alkaline solution, is converted by atmospheric oxidation into indigo.

The synthetically prepared indigotine caused the almost complete extinction of indigo culture of India. At one time the importations from India to the United States averaged about 2,000,000 lbs. a year; in 1902, less than 250,000 lbs. entered during the first six months and after June ceased entirely. During the Great War, however, the interference with the chemical industry caused a return to natural sources. In 1917 there was four times the total acreage in India devoted to the culture of the indigo plant that there was in 1914. (*C. D.*, 1917, lxxxix, 460.)

Schunck first showed that all urines, whether pathological or not, contain an indigo-producing body in minute quantities. This body is commonly spoken of as *indican* in medical books. Its true chemical nature was first ascertained by Baumann, who showed that it was not a glucoside, like the indican of plants, but the potassium salt of a peculiar acid, *indoxylsulphonic acid.*

Indigo carmine, $C_{16}H_8N_2O_2(SO_3Na)_2$, has been used as a test of the functional power of the kidneys, especially in surgical affections of these organs. The method consists essentially of the injection of 4 cc. of the 4 per cent. solution intravenously, the urine being collected separately from each kidney from 20 to 30 minutes after the injection. Healthy kidneys should excrete the drug within eight or twelve minutes, while if the kidneys are seriously affected the functional incapacity is shown by either the absence or the paleness of the urine.

Indigo was at one time considerably used in medicine, but at present is very rarely if ever employed. It is said to produce, when taken in sufficient quantity, nausea, vomiting, purging with bluish, dark stools, a dark violet or dark green color of the urine, and sometimes to cause menstrual flux. It was formerly used in *epilepsy, infantile convulsions, chorea, hysteria,* and *amenorrhea. Dose,* from twenty grains to an ounce (1.3–31 Gm.) three times a day. For further details, see 16th ed., *U. S. D.*

Indium. In.=114.8.—A rare metal named from the indigo blue line given by the spectrum of the metal. It is a shining white ductile metal, softer than lead. Some of its salts have been prepared and are asserted to be of value as external antiseptics. They are the sulphate, $In_2(SO_4)_3+nH_2O$, and the trichloride, $InCl_3$, a yellow hygroscopic powder. Both of these salts are active poisons.

Insect Powder. *Pyrethri Flores. Camomille de Perse,* Fr. *Persische Bertramblumen,* G.—The insecticide and Fungicide Board of the United States Department of Agriculture recognizes as insect powder an insecticide made from the powdered flower heads of *Chrysanthemum cinerariæfolium* (Trev.) Bocc., *C. roseum* Web. et Mohr and *C. Marschallii* Aschers, unexpanded or partly expanded flower-heads of several species of *Chrysanthemum* (Fam. *Compositæ*). There are two principal commercial varieties: (1) the Dalmatian insect powder which is obtained from *Chrysanthemun cinerariæfolium* (Trev.) Bocc., a perennial herb indigenous to Dalmatia and cultivated in the United States; (2) the Persian insect powder, obtained from *C. roseum* Web. et Mohr and *C. Marschallii* Aschers, perennial herbs indigenous to the Caucasus, Armenia and northern Persia and cultivated in Japan. The flower-heads are collected from plants that are from two to six years old, carefully dried and preserved. The most powerful insect powder is obtained from the closed or only partly expanded flower-heads providing they are properly dried and preserved. Insect powder containing more than 5 per cent. of naturally adherent flower-stems and 2 per cent. of acid-insoluble ash is held to be adulterated. No foreign matter is permissible under the ruling of the U. S. insecticide Bureau.

Dalmatian Flowers.—The heads are hemispherical, about 12 mm. in diameter, and consist of a conical torus subtended by a straw-colored campanulate and imbricate involucre, the bracts of which are slightly thickened or keeled; the torus bearing numerous yellow tubular flowers and a circle of cream- or pale straw-colored ray flowers. The latter are pistillate, the corolla being from 1 to 2 cm. in length, having about 15 delicately veined and 3 short, obtuse or rounded teeth. The achenes are 5-ribbed.

Persian Flowers.—The heads are flattened top-shaped; the involucral scales are greenish-brown and bordered by a reddish-brown edge; the ray florets are reddish-brown or reddish-purple, attaining a length of 15 mm., being somewhat plicate and having 7 veins. The disc florets are tubular, yellow, and 5-toothed. The achenes are usually 10-ribbed.

For details as to the special anatomical character of these flowers see *Bull. 824, U. S. Dept. Agri.*, 1920.

C. cinerariæfolium is now being cultivated on a large scale in California, and as more care is given to the preservation during drying of the color and of the volatile oil than in Dalmatia, the California product, which is known by the name of *buhach* is said to be superior to the foreign drug. (*C. D.*, August, 1889; see also for method of cultivation, *Reports of the Fourth U. S. Entomological Commission*, 1885, and papers by Seidler, *Riedel's Berichte*, 1913, and Jüttner, *Ph. Ztg.*, 1912, 817. At present *insect flowers* are cultivated commercially in Dalmatia, Australia, Japan, Montenegro, Algeria and California. Dalmatia, Montenegro, and Japan produce nearly all the flowers entering international commerce.

The insect powder of commerce varies in color from greenish-yellow to brown, the finer qualities verging towards brown and the poorer towards green. Brilliant yellow powder should be viewed with suspicion. On microscopical examination of an insect powder, it will be found to consist of fragments of involucral scales composed of sclerenchyma, perhaps bits of stems composed of collenchymatous cells, pollen grains, fragments of the corolla and of its epidermis and papillæ. The absence or scarcity of pollen in the powder shows the absence or scarcity of the flowers in the drug, while the proportion of collenchymatous tissue indicates the proportion of stems. As the activity of the insect powder resides in the flower, specimens containing little of the flowers or much of the stems should be rejected. The powder yielded by the Dalmatian plant can usually be distinguished from Persian insect powder by the following characters. The presence of somewhat rectangular patches of sclerenchyma tissue from the achene or ovary containing many diamond-shaped crystals. The outer surface and edges of the scales of the Dalmatian flowers contain numerous hairs, consisting of a long cell with attenuated ends placed horizontally upon a one- to three-celled stalk. The Persian flowers are almost entirely glabrous, a white hoariness being found only at and near the base of the scales, and very few hairs near the apex; the hairs are of the same structure as the preceding, only the terminal cell being much longer. Fragments of bracts with reddish-brown scarious margins are more striking in the Persian than in the Dalmatian powder. Sclerenchymatous cells are much more numerous in the Persian than in the Dalmatian.

The ground flower heads of *Chrysanthemum Leucanthemum* L. (Fam. *Compositæ*), a common weed in the United States and Europe (*daisy, ox-eye daisy, Hungarian* or *Russian daisy,* or *Marguerite*), have been employed for years as an adulterant of Dalmatian and Persian insect powder. The presence of this adulterant can be positively detected microscopically by the irregular dark red to reddish-brown, often angular, amorphous masses, from the resin canals of the daisy ovary or achene, as well as by the narrow, thick-walled palisade cells of the ribs of the achene. No such structures are present in insect flowers. According to George R. Durrant, the Hungarian daisy powder yields 10 per cent. of ash, whereas true insect powder yields but 6.5 per cent. F. Dietze, after careful study, found that the best chemical method of valuation of insect powder is based on the amount, appearance and odor of the extract obtainable by the use of petroleum spirits boiling under 55° C. With such menstruum true insect powder affords a bright yellow percolate possessing the odor peculiar to the drug. (See *P. J.*, 1905, 902; also 1906, 891; *Ph. Ztg.*, 1905, 871.)

The toxicity may be determined experimentally by injecting a weak alkali solution of the ether extract into the lymph sac of frogs; quantitative results may be obtained.

E. H. Gane, 1910, reports that insect powder is adulterated with ground stems and not ground from flowers only, as it should be. One sample from one of the largest pharmaceutical manufacturing houses was composed wholly of ground stems.

Insect powder does not appear to be actively poisonous to man, though it is said to cause some confusion of mind in those who sleep in close apartments where much of it is used and workers in factories where the powder is ground suffer with dermatitis. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, etc., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers for preserving dried insects and plants in cabinet collections. The powder, exhausted by alcohol, is harmless to insects. The active principle is not definitely known. Fujitani (*A. E. P. P.*, 1909, lxi, 47) believed it to be a neutral ester which he called *pyrethron;* this is a non-volatile substance of syrupy consistence. Gamamoto states that it is a mixture of esters. Reeb (*J. Pharm. Elsass-Lothringen*, 1909, xxxv, 267) attributed the activity to an acid which he called *pyrethrotoxic acid.* The presence of both of these substances has been confirmed by McDonnell (*Bulletin 824, U. S. Dept. of Agriculture,* 1920). In addition to these principles there is present *pyrethrum camphor* ($C_{10}H_{16}O$), an acrid resin, a volatile oil, an alkaloid (*chrysanthemine*), etc. The experiments of Zeigler (*J. A. Ph. A.*, 1923, xii, 19) seem to demonstrate that the active principle is of a resinous character and but very feebly toxic to mammals. The ash content varies from 5 per cent. to 8.3 per cent.

In a series of experiments, Riley has found that the fumes of the burning powder are very poisonous to insects, and for certain purposes afford a ready mode of application, but that generally an aqueous infusion is the best and cheapest preparation. It is also used now in the form of cones made by making a mass with mucilage of gum arabic, with the addition of a small quantity of potassium nitrate. After drying these are ignited like a fumigating pastile. Twenty-five grains stirred up in two quarts of water were sufficient to kill young cotton worms. The infusion soon spoils. The tincture and the alcoholic extract are both efficient preparations. The tincture (one part to four) has been especially recommended, diluted with ten times its bulk of water, by F. Jager, to keep off vermin from the human body. The commercial preparations known as "fly-sprays," to be used in the destruction of flies and other insects by the use of an atomizer, are made by extracting pyrethrum flowers with kerosene and adding volatile oils for masking the odor of the solvent.

Insindiyandiya.—This substance, a remedy of the Kaffir doctors of South Africa, is a violent poison, and has been shown by E. M. Holmes to be derived from a *Bersama,* apparently *B. abyssinica* Fresen. (*P. J.*, lxxiii, 893.)

Insipin. *Quinine Di-glycol Sulphate.* $O(CH_2.CO[C_{20}H_{23}O_2N_2])_2.H_2SO_4.3H_2O$.—This compound is very sparingly soluble in either water or alcohol, and is asserted to be practically tasteless. It was brought forward as a substitute for quinine. Werner (*D. M. W.*, 1911) has employed it in *malaria* in *doses* of from three to six grains (0.2–0.4 Gm.) given every three or four hours.

Intarvin.—Intarvin occurs in white greasy lumps having an odor resembling that of tallow. It consists approximately of 82 per cent. of *glyceryl margarate,* 12 per cent. of liquid petrolatum and 6 per cent. of water. It is intended as a food stuff for diabetics. The excessive amount of fatty foods which are necessary to maintain nutrition in cases of *diabetes* sometimes leads to the formation of large amounts of oxybutyric and diacetic acids, which are generally regarded as the immediate cause of the dreaded diabetic coma. On the theory that a fat containing an uneven number of carbon atoms could not split up into butyric acid, Kahn prepared this fat. Its present price, however, is so high as to practically preclude its use as a food except by millionaires. Its food value is said to be 6 calories per Gm.

Iodalbacid. *Albumen Iodate.*—An iodine-albumen compound which contains 10 per cent. of iodine in intramolecular combination. It is a cream-colored powder, inodorous, tasteless, and soluble in water. Iodalbacid is used in all cases where iodine is indicated, especially in *syphilis,* possessing the advantage of being less irritant to the stomach. It is especially recommended where protracted iodine action is desired. *Dose*, fifteen grains (1.0 Gm.) three to six times a day.

Iodalbin. *N. N. R.* 1924.—This is another iodine albumen product being soluble only in alkaline solutions. It is a reddish powder made by acting upon blood albumen with iodine and containing 21.5 per cent. iodine. It is used in preference to the alkali iodides due to its tastelessness, its freedom from harmful action on the stomach and to its ready assimilability. *Dose*, eight to fifteen grains (0.5–1.0 Gm.) several times daily.

Iodic Acid and its Salts. *Acidum Iodicum.* HIO_3.—*Iodic acid* occurs as a white, crystalline powder, soluble in its own weight of water. In concentrated solution it is caustic, and in solutions of 0.1 to 0.5 per cent. it is astringent and disinfectant. It has been employed as an astringent gargle and application to inflamed mucous membranes. Iodine acid is astringent and disinfectant and, like the other mineral acids, in concentrated solution caustic. In 1 to 3 per cent. solution it has been employed as a local application in *trachoma* and indolent *corneal ulcers*. Pencils made by adding iodic acid to powdered acacia have been used by Rudas in the treatment of *trachoma*.

The salts of iodic acid are physiologically more nearly related to the chlorates than to the iodides. They are more toxic than the chlorates, giving rise to a slow intoxication accompanied with inflammatory changes in the bowels and fatty degeneration of the liver.

The Br. formerly included a solution of *potassium iodate* among its test solutions. It was made by the mutual decomposition between iodine and potassium chlorate in the presence of nitric acid (see *U. S. D.*, 20th ed., p. 1561).

The iodates have been used chiefly as local remedies in the same manner as the chlorates.

The salts of iodic acid are actively disinfectant. According to Griffiths a 0.5 per cent. solution of potassium iodate is capable of destroying many forms of bacteria. Both potassium and *sodium iodate*, a white, odorless, crystalline substance, very soluble in water, have been used locally in inflammatory conditions of the mucous membranes for much the same purposes as sodium chlorate. As a local remedy it may be useful in tubercular and other inflammations of the nose and larynx, either pure or diluted. Ruhemann (*B. K. W.*, 1905) has employed sodium iodate in epidemic *cerebrospinal meningitis*. He administered four grains (0.25 Gm.) in water twice a day. Mackie (*L. L.*, 1905) recommends *zinc iodate* and *calcium iodate* as local applications in various suppurating *wounds*, *eczema*, *cystitis*, and similar conditions.

Iodine Trichloride. ICl_3.—This compound occurs in reddish-yellow crystals; very soluble in water and alcohol; rapidly decomposed with liberation of iodine and chlorine when brought in contact with organic matter. It has been especially recommended by Belfield (*B. M. J.*, Aug., 1892) as a powerful local antiseptic. A solution is prepared for medicinal use by suspending 5.5 Gm. of iodine in 22 Gm. of water, and passing in chlorine as long as it is absorbed by the well-cooled mixture; the resultant solution contains 10 Gm. of *iodine trichloride*. The strength of the solution used is 1 to 5 per cent. Gauze sterilized by boiling and immersing in 1 to 10 per cent. solution and dried is said to retain iodine trichloride indefinitely. Iodine trichloride is a very powerful germicide, at least four or five times as active as phenol. According to Rideal five parts in a hundred thousand will kill the bacillus typhosus after half an hour's exposure. The five per cent. solution is fairly permanent if protected from the light, but dilute solutions rapidly deteriorate. It has been used locally in infectious conditions of the various mucous membranes in strengths of from 1 in 1000 to 1 in 2000. For disinfecting the hands a one per cent. solution is recommended. It has also been used internally as a gastro-intestinal disinfectant in *doses* of one and one-half grains (0.096 Gm.) a day. Fourneau and Donard have suggested the use of *iodine monochloride* which they claim forms more stable solutions than the trichloride. A solution containing 1.5 parts per thousand is asserted not only to be an excellent antiseptic but completely devoid of caustic action.

Iodipin. *Iodized sesame oil. N. N. R.* 1924.—This is an iodine addition product of sesame oil containing between 9.8 and 11.2 per cent. of iodine. It is a yellowish oily liquid with a purely oleaginous taste.

Iodipin is used as a substitute for the alkaline iodides in the treatment of *asthma*, *arterial sclerosis*, etc. It is allied in its therapeutic effects to calioben (see *Calcii Iodobehenas*) and like this compound has the advantage of being less irritating to the stomach and more persistent in its action than the inorganic forms of iodine. For summary of the literature on this compound see McLean, *A. In. M.*, 1912, x, p. 505 and Jan., 1915.

The *dose* of iodipin is from 1 to 2 drachms (4 to 8 Gm.) three times a day. It should be protected from light. A stronger form of iodipin intended for veterinary use was formerly manufactured.

Under the name of *iodipinum solidum*, tablets of an emulsified iodipin have been put upon the market. Each of these corresponds to five-sixths of a grain (0.05 Gm.) of iodine. Three or four tablets may be given at a *dose*, and repeated several times a day.

Iodized Starch. *Amylum Iodatum. U. S.* 1880. *Iodide of Starch; Iodure d'Amidon*, Fr. *Jodstärke*, G.—"Starch, *ninety-five parts;* Iodine, *five parts;* Distilled Water, *a sufficient quantity*, to make *one hundred parts.* Triturate the Iodine with a little Distilled Water; add the Starch gradually, and continue triturating until the compound assumes a uniform blue color, approaching black. Dry it at a temperature not exceeding 40° C., and rub it to a fine powder. Iodide of Starch should be preserved in glass-stoppered vials." *U. S.*, 1880.

This preparation has been highly recommended as a means of obtaining the effect of iodine on the system free from local irritant properties. Dalton, of New York, found that nearly all the animal fluids decompose starch iodide and destroy its blue color. (*Am. J. M. S.*, April, 1856, p. 327.) This result is owing, no doubt, to the alkaline nature of most of the animal fluids, especially those of the duodenum, alkaline iodides being formed at the expense of the starch.

Lumière (*C. R. A. S.*, 1917, clxv, 376) has successfully employed an iodized starch, containing 1 per cent. of iodine as a *wound* disinfectant. The internal dose of the formerly official iodized starch is from 1 to 2 drachms (4–8 Gm.).

Iodival. *Iodisovaleryl Urea. Mono-iodo-isovaleryl Urea.*  $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!HC\text{–}CHI\text{–}CO\text{–}HN\text{–}NH_2$.—This is a white powder representing 47 per cent. of iodine. In cold water it is insoluble, but dissolves in alcohol and in hot water. It has been suggested as a substitute for the iodides in *syphilis*, *asthma, scrofula* and other conditions in which the iodides are employed. According to the investigations of Menne (*In. Dis.*, Bonn, 1909), it passes through the stomach unchanged but is dissolved and absorbed in the intestinal tract. Iodine appears in the urine in about an hour after its ingestion and the elimination is complete within two or three days. It is marketed in the form of tablets each containing five grains (0.32 Gm.). Of these tablets one may be taken from two to six times in the twenty-four hours.

Iodocasein. *Casein-iodine. N. N. R.* 1924.—A compound of iodine and casein obtained by precipitation of sodium casein solution by means of a potassium iodide and iodine solution. It is a yellowish-brown powder practically odorless and tasteless, insoluble in water and representing approximately 18 per cent. of iodine. It is used as a substitute for the inorganic iodides over which the advantage is claimed of being less prone to disturb digestion. *Dose*, five to twenty grains (0.32–1.3 Gm.). Another combination of casein and iodine is known as *Lactoiod* or *Proiodine*. This is asserted to contain 8 per cent. of iodine, but according to Stanieck (*Ther. Geg.*, 1909, p. 134) it contains only 5 per cent. He used it in *doses* of about one drachm (4 Gm.).

Iodoformin. *Iodoformolin. Iodoform Hexamethylentetramine.* $CHI_3(CH_2)_6N_4$.—Iodoformin is obtained through the action of an alcoholic iodoform solution on *methenamine*. It is a white crystalline powder of faint iodoform odor, fusing at 178° C. and insoluble in water. In boiling water or in wound secretions it is split up into its component parts yielding 75 per cent. iodoform. This compound not only is free from odor but appears to have direct antibacterial properties far in excess of that of iodoform. It is asserted to have especial toxicity for the gonococcus. It is used in medicine as a dusting powder to *wounds* and also as a local application in *urethritis*. For the latter purpose bougies containing 10 to 20 per cent. of iodoformin have been recommended.

The *iodoformin-ethyl-iodide*, $C_6H_{12}NC_2H_6ICHI_3$, known as *iodoformal*, is stated to be still more actively antiseptic. This is obtained through the action of iodoformin on ethyl iodide. It forms yellow needle-like crystals or a heavy powder. It dissolves in boiling water and fuses at 128° C. It is used for the same purposes as iodoformin.

Iodoformogen. *Iodoformalbumen.*—According to K. Gaab (*Ph. Centralh.*, 1898, xi, 189), *iodoformogen* is a chemical combination of iodoform and albumin. It occurs as a fine, loose, dry, nonconglutinating powder, having a faint aciduloethereal odor, and being two and one-half times as voluminous as powdered iodoform. According to Kromayer (*B. K. W.*, xxxv, 1898) and to Aspegren (*Festschrift des Prof. Kaposi*, Vienna, 1901), iodoformogen is more slow and continuous and certain in its local action than is iodoform. It bears sterilization at 100° C. without change.

Iodol. *Iodolum. U. S. VIII.* $C_4I_4.NH$. *Tetraiodopyrrol. Iodopyrrol. Pyrrol Tetraiodide. Jodol, Tetrajodpyrrol,* G. *Jodolo,* It. *Yodol,* Sp.—*Iodol* was discovered by Silber and Ciamician, and is made from the pyrrol obtained in Dippel's oil (bone oil), which, after purifying, is treated with a solution of iodine in potassium iodide, when the tetraiodide (iodol) precipitates. It is purified by redissolving in hot alcohol, and again precipitated by the addition of water. It contains nearly 89 per cent. of iodine. It should be protected from the light.

Iodol was official in the United States Pharmacopœia VIII. It was officially described as "a odor or taste. It is soluble in about 4900 parts light grayish-brown, crystalline powder, without of water, 9 parts of alcohol, 1.5 parts of ether, and 105 parts of chloroform at 25° C.; soluble in fixed oils. It is soluble in concentrated sulphuric acid, producing a green solution gradually changing to brown. When heated to 100° C. it remains unchanged, but at a temperature of 140° to 150° C. it is decomposed with the liberation of violet iodine vapors. When ignited it should leave not more than 0.1 per cent. of residue (limit of *inorganic impurities*). If 0.5 Gm. of Iodol be shaken with 100 cc. of water and filtered, the filtrate should not be made more than slightly opalescent by silver nitrate T.S. (absence of *hydriodic acid* or soluble metallic *iodides*). If 0.5 Gm. of Iodol be shaken with 100 cc. of water and filtered, the filtrate should not communicate more than a light yellowish tinge to chloroform (absence of appreciable amount of *free iodine*)." *U. S. VIII.*

When given in sufficient dose to animals, iodol causes emaciation, albuminous urine, fall of temperature, general loss of muscular power, and finally death from fatty degeneration of the liver and kidneys and other tissues. That iodol applied externally is capable of producing constitutional symptoms is shown by C. Lauenstein (*T. G.*, 1887, 768), in a case in which the surgical use of the drug caused dizziness, marked rise in the temperature, vomiting, small, rapid, irregular pulse, albuminous urine, and apathy which did not subside for four days, iodine was found in the urine for twelve days. It is, however, a less dangerous topical application than iodoform due to its slower absorption. Iodol may be employed for all purposes for which iodoform has been used. It has been found valuable in the treatment of *tuberculous laryngitis*, and may be blown into the larynx directly upon the ulcers without causing irritation. It has been used with asserted great success in the treatment of blennorrhagic and simple *vaginitis*, in *chancres* and other *ulcers*, in suppurative *adenitis*, and as an antiseptic dressing to *wounds*. Mazzoni's solution was: iodol, one part; alcohol, sixteen parts; glycerin, thirty-four parts. Iodol has also been used as an internal remedy in *tertiary syphilis* and in *scrofula*. Good effects have also been claimed for it in *diabetes*. Assaky and Reck have given thirty grains (1.9 Gm.) a day with asserted good results. *Dose*, two to four grains (0.13–0.26 Gm.). Under the name of *iodolen*, a compound of iodol with albumin has been used as a surgical dusting powder.

Iodolein. *Dubois's Iodolein. Iodized Poppy Seed Oil. N. N. R.* 1924.—This compound is an oily brownish liquid containing about 33 per cent. of iodine. It is used as a substitute for the inorganic iodides in *doses* of from 2 to 10 minims (0.13 to 0.6 cc.) taken in capsules after meals.

Iodolin. *Quinoline chlormethylate iodochlorid.* $C_9H_7NCH_3Cl.ICl$.—This is a yellow insoluble powder used as an iodoform succedaneum. It is the product of the action of a chloride on quinoline and methyl iodide.

Iodopyrine. $C_{11}H_{11}IN_2O$. *Antipyrine Iodide, Iodantipyrine.*—This substance contains 60 per cent. antipyrine and 40 per cent. of iodine. It forms colorless crystals melting at 160° C., and has been recommended as a substitute for the iodides in *muscular rheumatism* and in *asthma* and *syphilis.* It is capable of producing iodism. It has also been used as an analgesic in *neuralgia* and *herpes zoster* and as a local application in *syphilitic sores* and *psoriasis.* The *dose* given by Junkers was fifteen grains (1 Gm.) for adults every three or four hours. For children from 1 to 10 years old he gave one and a half to eight grains (0.096–0.5 Gm.). To those over 10 years he gave eight to twelve grains (0.5–0.78 Gm.). (*Th. M.*, vol. xiii, 604.)

Iodostarin. *Diiodo-tariric Acid. N. N. R.* 1924.—This is an addition product with a fatty acid, tariric, derived from a species of *Picramnia* (formerly *Tariri*), see *Cascara amarga.* It has the chemical formula $CH_3.(CH_2)_{10}CI = CI.(CH_2)_4CO\text{-}OH$. It forms white, shining, crystalline scales, which are odorless and tasteless, containing 47.5 per cent. of iodine. It is insoluble in water, slightly soluble in cold alcohol, readily soluble in hot alcohol, in ether, chloroform and benzol. Iodostarin itself is not affected by light, but its solutions, after short exposure to light, turn brown with separation of iodine. Bachem (*M. M. W.*, 1911) has shown that the iodine is much more slowly eliminated after the exhibition of iodostarin than after alkaline iodides. Its action is similar to that of calioben. It is marketed only in the form of tablets each containing 4 grains (0.25 Gm.).

Iodosyl $C_6H_3I.OI.COOH$.—A bulky, amorphous powder of a deep red color, nearly odorless, and having only a faint taste suggestive of that of iodine. Insoluble in water and in oils and only sparingly soluble in chloroform and ether. It is used as a substitute for iodoform, over which it has the advantage that it is odorless, as a dressing for *wounds* and *ulcers,* Also as a local application in *nasal catarrh* and *ozena,* in *ringworm* of the scalp, in various *cutaneous affections,* being especially recommended in the treatment of *corneal ulcers.* It is employed either as a dusting powder, in the form of an ointment, 2 to 10 per cent., or in that of a medicated gauze.

Iodylin. *Iodiline. Bismuth-iodo-salicylate.*—It is a fine, yellowish-green powder with an odor suggestive of that of iodoform. According to Israel (*Med. Wochens.*, 1902, p. 139), this substance is efficient as a substitute for iodoform.

Iogen.—Iogen is produced by the action of iodine upon the anhydride of phthalic acid. It is a lustrous crystalline compound of dark green color, liberating 52 per cent. of iodine in the presence of moisture. It is claimed to be antiseptic and germicidal, and is used, in about 4 per cent. strength, in oil for the treatment of nose and throat affections, in ointment for application to the skin or to wounds, or as an antiseptic dusting powder.

Ionidium.—A species of *Ionidium* growing in Ecuador, in the neighborhood of Mount Chimborazo, was used by the South American Indians in the treatment of *elephantiasis,* under the name of *cuichunchulli.* It was probably derived from the *Ionidium glutinosum,* Vent. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. For further information, see *A. J. P.*, iii, 125.

Iopropane. *Iothion. N. N. R.* 1924. *Di-iodohydroxypropane,* $C_3H_5I_2(OH)$.—It is a thick, yellowish liquid, soluble in alcohol, ether, and the fixed oils, but almost insoluble in water. It contains from 77 to 80 per cent. of iodine.

Iothion is intended as a means of endermic administration of iodine. It is asserted that after its external application, iodine appears in the saliva within an hour, and that from 30 to 50 per cent. of the amount of the substance employed can be eventually recovered from the excretions. It has been used to a considerable extent in the treatment of *tertiary syphilis, asthma, chronic arthritis,* and other conditions in which iodine is indicated. (See Richter, *B. K. W.*, 1909.) It is applied generally in the form of an ointment containing from ten to fifty per cent. of iothion, of which a quantity equivalent to fifteen to thirty grains (1–2 Gm.) may be well rubbed into the skin once a day.

According to Herzfeld and Makler (*Med. Klin.*, 1912), a portion of the iodine is retained in the organism. It is used in the treatment of *syphilis* and other conditions in which a continued iodine effect is desired. Herzfeld and Elin (*Med. Klin.*, 1912) found 50 per cent. of the iodine in the urine after application of a 10 per cent. iothion ointment.

Iridium. *Ir.*—This metal, discovered in 1804, and named after Iris, the goddess of the rainbow, is a white lusterless, steel-like metal of the platinum group. It has a sp. gr. of 22.7 and is the heaviest of all metals. Several of its salts and compounds of its salts with other salts, usually of the alkali group, are prepared and marketed. Of these but one, the bromide, is used in medicine, and even this has failed to show any decided therapeutic value.

Iotriferrin.—This is a reddish powder with metallic taste and a faint odor of iodine. It is said to contain 15 per cent. of iron, 8 per cent. of iodine and 2 per cent. of phosphorus. It is insoluble in water or acid media but readily soluble in alkaline solutions. It is intended for the treatment of *anemia* and *scrofula.*

Iron-Wood. *Ostrya virginiana* (Mill.) Willd. (*O. virginica* Willd. *Carpinus virginiana* Mill.) (Fam. *Betulaceæ.*)—The wood of the *hop-hornbean* is said to be tonic, antiperiodic, and alterative, and the fluidextract has been used in *doses* of from a half to one fluidrachm (1.8–3.75 cc.) in *ague.*

Isatis. *Isatis tinctoria* L. *Woad. Dyer's Woad. Pastel.* (Fam. *Cruciferæ.*)—A glabrous and glaucous biennial plant, indigenous to and cultivated in southern and central Europe to central Asia, as well as in the United States. *Dyer's woad* is mentioned in the writings of Dioscorides and Pliny. It produced the chief blue coloring-matter for woolen fabrics in Europe before indigo became common. The first year's growth consists of a rosette of lanceolate leaves. During the second year a stem rises to the height of 2 to 4 ft. bearing alternate, lanceolate, entire, sessile leaves, panicled racemes of yellow flowers and 1-celled samara fruits. The leaves have a fugitive, pungent odor, and an acrid, very persistent taste; they have been used in *scorbutic affections, jaundice,* and other complaints, but are of no value. They were formerly of importance as a source of indigo. (See *Indigo.*) The leaves are prepared by grinding them to a paste, which is made into balls placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is woad.

Isocain. This name has been applied to the para-amino-benzoyl-di-iso-propyl-amino-ethanol hydrochloride. Schmitz and Loevenhart (*J. P. Ex. T.*, 1924, xxiv, p. 167) find that it is approximately equal to cocaine in its anæsthetic effects on mucous membranes, is six times as powerful in its nerve blocking action and less than one-third as poisonous. We do not, however, know of any clinical reports.

Isoform. *Para-iodoanisol.* $C_6H_4(OCH_3)IO_2$.—It is a white powder having an odor feebly suggestive of aniseed. It is sparingly soluble in cold water, but dissolves more freely in hot water. In alcohol and ether it is insoluble. When heated to about 225° C. it decomposes explosively.

Because of its explosive properties it is marketed only mixed with equal parts of calcium phosphate—if intended for a dusting powder—or as a paste with equal parts of glycerin.

According to Winterberg (*Med. Klin.*, 1906), *isoform* in 1 per cent. strength has a distinct, and in 3 per cent. strength, a well marked antiseptic action. It has been used to a considerable extent as a surgical dressing, especially for suppurating *wounds.* It is applied either in the form of a dusting powder or by saturating gauze with it, or in paste or emulsion, as the conditions may indicate. It has also been employed as an antiseptic in purulent *otitis media,* various *skin diseases, urethritis,* and in tooth paste. Although Heile has stated that isoform is non-toxic, Hoffman (*B. K. W.*, 1905) has reported violent dermatitis from its use, and Urbantschitch (*W. K. R.*, 1907) asserts that it has a depressant action upon the central nervous system.

Isopropyl Alcohol. $(CH_3)_2CHOH$. *Dimethylcarbinol.*—It is a by-product of the petroleum and natural gas industries. The anhydrous alcohol has a specific gravity of 0.789 and boils at 82.4° C. The commercial product contains 91 per cent. by volume of the alcohol with 9 per cent. of water. It is a colorless liquid with a somewhat bitter taste and a characteristic odor, miscible in all proportions with water. (For further details see paper by Grant and Johns, *A. J. P.*, 1922, xciv, p. 418). Its solvent properties are similar, but not identical with those of ethyl alcohol. *Isopropyl acetate* has been prepared by Grant and Johns and is a useful solvent for nitrocellulose.

Macht (*J. P. Ex. T.*, 1920, xvi, p. 1) found that isopropyl is about twice as poisonous as ethyl alcohol but that it does not produce the permanent, injurious effects characteristic of methanol. It has been suggested for various purposes in the arts and pharmacy, especially for the extraction of resins and in the preparation of substances intended for external application. In medicine it has been used to a limited extent as a solvent for phenol, as a wound dressing in the place of grain alcohol and for the preparation of various lotions intended for external use.

Isopral. *Trichlorisopropylalkohol,* $CCl_3.CHOH.CH_3$.—This substance, which has been proposed as a hypnotic, occurs in microscopic prisms, melting at 49° C., readily soluble in water, alcohol, or ether, readily subliming and having a camphor-like odor and aromatic taste. Heated for a long time with alkalies it loses chlorine without the formation of chloroform. According to Impens, it is readily absorbed through the skin, subcutaneous tissue, and the digestive tract, the impression, when taken internally being manifested in from three to five minutes. It is said, also, that the inhalation of a stream of air directed over warmed isopral will produce marked narcosis in the lower animals in ten or twelve minutes. It is eliminated through the kidneys chiefly as a compound with glycuronic acid (*trichlorisopropylglycuronic acid*) although it is believed also to escape to some extent through the respiratory tract.

The experiments of Hatcher (*J. A. M. A.*, 1907) have shown that, although weight for weight it is somewhat more powerfully somnifacient than is chloral hydrate, it is correspondingly more toxic, so that in its therapeutic efficiency it is about the same. The *dose* is ten to twenty grains (0.65–1.3 Gm.).

Isopyrum. *Isopyrum thalictroides* L. (Fam. *Ranunculaceæ.*)—F. A. Harsten believes he has found two alkaloids, *isopyrine* and *pseudo-isopyrine,* in the root of this plant, which grows in the forests of middle and southern Europe. (*A. J. P.*, xliv, 453. See also *J. Soc. Chem. Ind.*, 1919, xxxviii, 197A.)

Issue Peas.—These were globular beads, of the size of a pea, made of woody substances of spongy structure, intended to be introduced into issues, abscesses, etc., for the purpose of promoting suppuration. They are not used by modern surgeons.

Istizine.—Under this name a synthetic dioxyanthraquinone has been introduced as a purgative. It occurs as an orange-yellow crystalline powder, difficultly soluble in water or the ordinary organic solvents, but an alkaline solution dissolves it with the formation of a cherry-red color. Ebstein (*Med. Klin.*, 1913) has used it as a laxative in *doses* of two to eight grains (0.13 to 0.5 Gm.).

Iwarancusa.—The roots of *Andropogon Iwarancusa* Boiss., now considered to be in large part *A. Schoenanthus* L. (Fam. *Gramineæ*), a native of Central India (see *Oil of Citronella*). It contains a volatile oil, resin, and a bitter substance, and is stated to be used on the continent as a diaphoretic drug. It is also used in perfumery. In India it has been reputed to be of service in *cholera.*

Ixora.—The *Ixora coccinea* L. (Fam. *Rubiaceæ*), a smooth shrub with oblong leaves and corymbs of red flowers and indigenous to the East Indies, is used in India in the treatment of *dysentery.* According to Ghosh it is second in value only to ipecac. (*P. J.*, 1916, xcvii, 369.)

Izal. *N. N. R.* 1924.—This is an albuminous emulsion containing not less than 50 per cent. of "izal oil," a coal tar fraction of monatomic phenols exclusive of cresols and phenol. It is used as a germicide and disinfectant. It is stated to be twelve times as efficient as phenol, with a lower degree of toxicity. It is not intended for internal use but is employed externally or as a household disinfectant in dilutions of from one-third to one per cent.

Jacaranda.—Several species of this genus (Fam. *Bignoniaceæ*) are employed in *syphilis* in Brazil and other portions of South America under the names of *caroba, carobinha,* etc. Peckolt (*A. J. P.*, 1882, 134) has found in them a crystalline substance, *carobin,* besides resins and acids, such as *carobic* and *steocarobic acids,* and *carobon, caroborelinic acid,* and *caroba balsam.* Hesse (*Ann. Chem.*, cclii, 150) found only an aromatic resin, but no alkaloid. The value of the remedy has been asserted in the *B. M. J.*, vol. i, 1885. For further information, consult *P. J.*, 3d series, vols. v, xii, and xiv, and also *A. J. P.*, 1882.

Jambosa Root.—This is the root of *Eugenia Jambos* L. (*Myrtus Jambos*) (*Jambosa vulgaris* DC.), a tree, with lanceolate leaves and greenish-white flowers belonging to the *Myrtaceæ,* which is widely cultivated in the tropics under the name of the *rose-apple.* It has been found by A. W.

Gerrard to contain an oleoresin, besides a crystalline principle, *jambosin*, $C_{10}H_{15}O_3N$. Lyons has also found in it minute quantities of an alkaloid. The decoction of the bark of the root is used as an astringent in *dysentery*, *gonorrhea*, and *leucorrhea*. (*P. J.*, March, 1884.)

Jambu Assu.—The root of *Piper Jaborandi* Vell. (Fam. *Piperaceæ*) of Brazil, is used by the natives as a sudorific, a diuretic, and a febrifuge. It is said to contain an alkaloid and a pungent oleoresin. It has no botanical, and probably no medicinal, relation with pilocarpus.

Jeffersonia. *Twinleaf. Rheumatism Root. Jeffersonia diphylla* (L.) Pers. (Fam. *Berberidaceæ.*)—This is a low perennial herb found in woods from New York to Wisconsin and Iowa extending southward. It possesses long-petioled, 2-lobed or parted radical leaves and a naked scape bearing a single terminal white flower. The rhizome, which, with the matted fibrous rootlets attached, is the part used, has a brownish-yellow color, and a bitter, acrid taste, which resides in its cortical part, the inner portion being nearly tasteless. E. S. Wayne, of Cincinnati, found it to contain albumen, gum, tannic acid, starch, pectin, a fatty resin, hard resin, sugar, lignin and a peculiar acrid principle having acid properties and resembling polygalic acid. The root is said to be emetic in large doses, tonic and expectorant in smaller doses and not unlike senega, as a substitute for which it is sometimes used. (*A. J. P.*, xxvii, 1.) According to Mayer, of New York, the rhizome of this plant contains a small quantity of berberine and a second white alkaloid. The pectin of Wayne he considers to be saponin. (*A. J. P.*, 1863, 99.) A. W. Flexor proved the absence of berberine from the root. (*Am. Drug.*, 1884.) Gordin has since confirmed this view (1902).

Job's Tears. *Coix Lacryma. Semen Lacrymæ Jobi.*—This seed is from *Coix Lachryma-Jobi*, a graminaceous plant growing, under favorable conditions, to a height of seven or eight feet. It is a native of the East Indies but is extensively cultivated not only in the Orient but in parts of Europe and America. The seeds are about one-quarter inch in length, round at one end and pointed at the other, and with a very hard siliceous coat of a pearly gray appearance. They have been used in medicine either as a tincture or decoction in catarrhal affections of the air passages and in inflammation of the urinary passages. They are very frequently strung and used as beads to make necklaces, in the superstitious belief that they protected the infants from the ills incident to teething.

The continued search for food products by the U. S. Department of Agriculture has brought attention to the fact that these seeds are used extensively as food in some parts of the world under the name of *adlay*.

The outer hard shell of the individual grains constitutes 75 per cent. of the total weight of the seed. The varieties raised for food purposes are numerous and a species has been developed which has a softer outer coat, and the milling expert of the U. S. Department of Agriculture has found that good flour can be made with ordinary milling equipment.

Seven distinct varieties of the plant have been found in the Philippines and still other varieties grow in Burmah and other Oriental countries. The high yield per acre, which averages over 2000 pounds or about three times that of wheat, makes it a lucrative crop from an economic standpoint. The chemical analysis shows the following composition: (in parts per hundred).

Water, 8.49; protein, 17.58; fat, 7.15; crude fiber, 2.04; soluble carbohydrates, 6.24; ash, 2.33; starch, 51.58. The protein is similar to gliadin. Its distinctive character has led the Japanese investigators, Yoshimura and Sagara, to name it *coicin*. (*Jour. Tokio Chem. Soc.*, 1919, p. 483.)

Juniperus Virginiana L. (Fam. *Coniferæ*) *Red Cedar. Cèdre de Virginie*, Fr. *Virginische Ceder, Rothe Ceder*, G.—The *Red Cedar* is a slow growing, evergreen tree with shreddy bark and a crown which is usually narrow, dense and pyramidal but which occasionally, in old plants, becomes spreading and round-topped. It grows on dry hills or in swamps from Nova Scotia to Florida and west to the Rocky Mountains. In northern latitudes it usually attains a height of 25 to 40 feet but, in the south, specimens attaining 100 to 120 feet in height are recorded. Its leaves vary from acicular to scale-shaped. The acicular type, occurring on young trees and vigorous shoots are opposite and scattered, the scale-shaped type which are the more common are bluish-green, about $^1/_{16}$ inch long, glandular on back and 4-ranked, giving the twigs an angular appearance. Both staminate and pistillate flowers occur, either on the same tree or on different trees, in catkins. The staminate flowers are yellow, each with numerous anthers attached to several scales that are united into an ovoid catkin; the pistillate flowers are greenish, minutely globular with about 6 bluish scales. Upon ripening these scales become fleshy and connate producing a dark-blue berry-like fruit, termed a galbulus, which is often covered with a bloom.

The tops of this plant were formerly included in the Secondary List of the U. S. Pharmacopœia. The wood, which is characterized by its red duramen and nearly white alburnum, yields valuable oil which is used as a clearing agent in microscopic technique. When evaporated to a thick consistency, it furnishes the *immersion-oil* for use with oil-immersion objectives. The wood itself is extensively used for moth-proof chests, lead-pencils, fence posts and furniture. Small excrescences, which are sometimes found on the branches of the tree, are popularly known as *cedar apples* and used as an anthelmintic in the *dose* of from ten to twenty grains (0.65–1.3 Gm.) three times a day. The tops have a pleasant odor, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in a volatile oil, and are readily imparted to alcohol. The leaves bear a close resemblance to the leaves of *Juniperus Sabina* L., an European shrub, from which they can be readily distinguished by the strong, disagreeable odor of the latter, after bruising. I. W. Brandel obtained from the leaves of *J. Virginiana* 0.47 per cent. of volatile oil, sp. gr. 0.913 at 15° C. It had a very pleasant odor. (*Proc. A. Ph. A.*, 1906, 459.) *Cedrene camphor*, $C_{10}H_{26}O = C_{16}H_{24} + H_2O$, may be obtained by cooling the oil until coagulated, and separating the crystalline portion by expression; the expressed liquid is *cedrene*, $C_{15}H_{24}$, which, after rectification and distillation, has the sp. gr. 0.984 at 15° C., boiling at 237° C. Cedrene may also be prepared from the cedrene camphor by the dehydrating action of phosphoric anhydride, P_2O_5. *Oil of cedar wood* and *oil of cedar leaves* are both articles of commerce. Schimmel describes a volatile oil from Haitian cedar wood which differs from our domestic oil of cedar, only in having a higher specific gravity. (*Schim. Rep.*, 1905, 17.)

The volatile oil, which resembles oil of savin in its medicinal properties, has been used for the purpose of producing abortion, and in some cases has caused death. The symptoms have been burning in the stomach, vomiting, convulsions, coma. and a slow pulse, with evidences of gastro-intestinal inflammation after death. (See S. C. Watt, *B. M. S. J.*, vol. xl.) A counterirritant ointment was formerly made from the leaves.

Under the name of *cedar* are known in commerce various trees, some of which do not belong to the genus *Juniperus.* The wood of *Juniperus bermudiana* L. is said to be largely used in making pencils. The cedar of Lebanon, *Cedrus Libani* Loud. and two allied species, the *African cedar*, *C. atlantica* Manetti, and the *Indian cedar* or *deodar*, *C. Deodara* Loud., are sometimes distilled for oil. Under the name of *libanol*, an oil obtained from *Cedrus atlantica* Manetti, or *satin-wood*, has appeared in commerce and is said to be useful in the treatment of *blennorrhagia*, *phthisis*, *bronchitis*, and *eruptions* upon the skin, having properties very similar to those of the oil of santal. It may be given in capsules up to forty-five grains (3 Gm.) per day. In skin eruptions the 25 per cent. ointment made with vaseline has been used. Other trees known as cedars are the *white cedar*, *Cupressus thyoides* L. (*Chamæcyparis thyroides* (L.) Brit); the American white cedar, *Thuja occidentalis* Linn.; the Californian white cedar, *Libocedrus decurrens* Torr.; the New Zealand cedar, *Libocedrus Bidwillii* Hook. The Australian red cedar, *Cedrela Toona* Roxb., and the West India cedar, *Cedrela odorata* L., belong to an entirely different family, the *meliaceæ* (*Cedrelaceæ*). The wood of the latter species is used in making cigar boxes, and, according to Schimmel, yields 3 per cent. of a volatile oil, which has a specific gravity of 0.915, boils between 265° and 270° C., and has an optical rotation of 0.053° in a 100 mm. tube. It is said to be a powerful insecticide. (*P. J.*, Aug. 29, 1896, 179.)

Kairine.—The hydrochloride of methyloxytetrahydroquinoline, $C_{10}H_{13}ON.HCl + H_2O$), is the commercial kairine (*kairine M*). *Kairine A* is the corresponding ethyl compound, and has similar properties. Kairine, as brought into commerce, is readily soluble in water and alcohol, and forms a grayish-white crystalline powder, with bitter, salty taste. Ferric chloride produces a dark brown color, which upon the addition of sulphuric acid turns purple.

Kairine belongs to the antipyretic remedies, and is without doubt capable of producing pronounced fall of temperature in *fever*, accompanied by copious sweating. It is, however, a cardiac depressant, which is said to act directly upon the cardiac muscles, and is very prone to produce cyanosis and collapse. The reports have been so unfavorable that, in the absence of advantage over antipyrine and antifebrine, kairine is no longer used in practical medicine. *Dose*, five to ten grains (0.32–0.65 Gm.).

Kalagua.—A study of this South American plant, which has been put upon the market as a specific for *tuberculosis*, made upon the lower animals by D. H. Bergey, shows that it has no specific influence upon the tubercle bacillus.

Kalmia. *K. latifolia* L. (Fam. *Ericaceæ*) *Laurel. Mountain* or *American Laurel. Broad-leafed Laurel. Calico-bush. Spoonwood. Kalmie*, Fr., G.—This is an evergreen shrub with a round-topped head from 4 to 10 feet in height, rarely tree-like. It is indigenous to rocky hills and mountains as well as pine barrens from New Brunswick and Ontario south to Florida and Tennessee. Its leaves are mostly alternate, entire, elliptic-lanceolate, dark green on upper and yellowish to bright-green on lower surface. Its flowers are pink, rose-colored or white with purple markings, have a cup-shaped corolla with 10 stamens, and are arranged in terminal compound corymbs. Its fruit is a small capsule. The leaves and tops are poisonous. In the leaves George W. Kennedy detected the glucoside arbutin. (*A. J. P.*, xlvii, 5.)

Kalmia angustifolia L. (Fam. *Ericaceæ*) *Sheep Laurel. Lamb Kill. Wicky.*—This is a low undershrub usually attaining a height of 1½ to 2 feet with opposite or whorled, entire, oblong leaves that are dark-green on upper surface and pale-green beneath. Its flowers are smaller than those of *K. latifolia;* crimson to light purple in color and are borne in lateral, many-flowered corymbs. Its fruit is a small capsule. This species is indigenous to pastures, hillsides and peat bogs from Newfoundland and Hudson Bay to Georgia.

Both the *Kalmia latifolia* and the *K. angustifolia* are not infrequently the source of serious and even fatal poisoning to sheep although it is said that they are eaten with impunity by deer and goats. According to Crawford (*Bulletin 121, Bureau of Plant Industry*, U. S. Dept. of Agriculture), laurel causes either when fed to, or injected into, the lower animals, great salivation, lachrymation and emesis, convulsions, and later paralysis of the extremities, with greatly labored respiration. The toxicity of these plants is due, according to De Zaayer (*Chem. Ztg.*, July, 1887), to andromedotoxin (see *Andromeda*). The leaves have been used internally in *diarrhea* and in *syphilis*, and externally in skin diseases. (See 16th edition, *U. S. D.*)

A decoction of the leaves of *K. angustifolia* is used by the negroes as a wash for ulcerations between the toes.

Kamala. *U. S.* 1890. *Kamala. Glandulæ Rottleræ.*—The U. S. Pharmacopœia, under the name of *Rottlera*, U. S., 1870, *Kameela*, formerly recognized the glands and hairs from the capsules of *Mallotus philippinensis* (Lamarck) Muell.-Arg. (Fam. *Euphorbiaceæ.*) This tree grows in Abyssinia, Southern Arabia, Hindostan, the East India Islands, China, and Australia, reaching a height of from fifteen to twenty feet, and yielding a roundish, three-valved, three-locular capsule about the size of a small cherry, thickly covered with a red powder, which is collected in Hindostan by rolling the berries about in large baskets until the free powder sifts through the open wickerwork. This powder has been used for many centuries in Asia as a dyestuff under the name of *wars*, although this term is more properly applied to the product of the *Flemingia.* (See *Wurrus.*)

Kamala, as brought to our market, is a light, finely granular, very mobile powder, of a brownish-red or madder color, with little odor or taste, but producing a slight sense of acridity in the mouth, and feeling gritty under the teeth. (When the grittiness is excessive, the drug has probably been adulterated with earthy matters.) It is inflammable, and flashes almost like gunpowder when dropped into the flame of a candle. It is insoluble in cold and but very slightly soluble in boiling water; but alkaline solutions, alcohol, and ether dissolve a large proportion of it, forming a deep red solution, from which water precipitates resinous matter, "imparting a deep red color to alkaline liquids, alcohol, ether, or chloroform, and a pale yellow tinge to boiling water." *U. S.*, 1890. Under the microscope it consists of garnet-red, semi-transparent, roundish, glandular hairs from 0.040 to 0.100 mm. in diameter, containing numerous red, club-shaped cells admixed with minute aggregate hairs, and the remains of stalks and leaves, the latter of which are easily removed by careful sifting. It has been examined chemically by Thomas Anderson, of Glasgow, and by G. Leube, in Germany. As given by the former, the constituents are, in 100 parts, 78.19 of resinous coloring matter, 7.34 of albumin, 7.14 of cellulose, etc., a trace of volatile oil and volatile coloring matters, 3.84 of ash, and 3.49 of water. The amount of earthy impurities, chiefly sand, in commercial kamala, varies greatly, sometimes amounting to fifty or even sixty per cent. It can readily be detected by a high ash percentage. The U. S. P., 1890, permitted the presence of "not more than 8 per cent. of ash." Rusby found one shipment loaded with sand, one with olive stems, one olive stems and sand, and one ground bark. Two samples, 40.8 per cent. acid, 43.4 per cent. ash, were mostly sand. (See also *Ph. Rev.*, 1907, 129; *P. J.*, 1906, 258.) Of the resinous coloring substances, Anderson obtained one in a pure state by allowing a concentrated ethereal solution to stand for two days, draining and pressing in bibulous paper the resulting mass of granular crystals, and purifying them from adhering resin by repeated solution in ether and recrystallization. To this substance he gave the name of *rottlerin.* It is in the form of minute crystalline plates, of a yellow color and a satin-like luster, insoluble in water, sparingly soluble in cold but more so in boiling alcohol, and readily dissolved by ether, and by alkaline solutions, which assume a dark red color. Perkins (*Chem. Soc. Trans.*, lxiii, p. 975) shows rottlerin to consist of six distinct substances, *i. e.*, rottlerin, isorottlerin, wax, two resins and a coloring substance. The pure rottlerin has the chemical composition $C_{33}H_{30}O_9$. (See also *Ph. Ztg.*, 1906.) Crude rottlerin, sometimes known as *kamalin,* melts when heated moderately, and at a higher heat is decomposed, giving off pungent vapors. A. and W. Perkin (*B. Chem. G.*, xix, 3109) and Jawein (*B. Chem. G.*, xx, 182) both stated that rottlerin can be extracted from kamala by the action of carbon disulphide. Jawein gave its fusing point as 200° C., and said that it was easily soluble in hot alcohol and acetic acid. In a later communication, A. G. Perkin (*P. J.*, 1893, 159, 236) stated that there is also present a trace of a yellow crystalline coloring matter melting at from 192° to 193° C. Perkin also found in kamala a small quantity of a sugar soluble in water. Potassium permanganate oxidizes it to oxalic and benzoic acids; nitric acid of 1.5 sp. gr., on the other hand, oxidizes it to oxalic acid, ortho- and para-nitrocinnamic acids, and para-nitrobenzoic acid.

Kamala is actively or even violently purgative in full doses, occasionally causing nausea, but seldom vomiting. Kamala has long been used in India against the *tape worm.* Semper (*A. E. P. P.*, 1910, lxiii, p. 10) has found that kamala has a paralyzing effect on motor nerves and muscles, to which action he believes it owes its tænifuge powers. It is given, without previous preparation of the patient, in the *dose* of from one to three drachms (3.9–11.6 Gm.), suspended in water, mucilage, or syrup. In the latter dose it sometimes acts violently. The worm is usually expelled at the third or fourth stool. If the first dose fails to operate on the bowels, it may be repeated in four hours, or followed by a dose of castor oil. The tincture (four ounces to eight fluidounces of diluted alcohol) is also said to be efficient in *doses* of from one to four fluidrachms (3.75–15 cc.). As an external remedy, kamala is used by the people of India in various affections of the skin, particularly *scabies* and *ringworm.* A tænifuge composed of kamala and koussin and known as *kamakosin,* is in use on the continent.

Kauri. *Cowrie. Gum Kauri. Australian Copal.* —This is an amber-like substance, varying from a soft cream-white to an amber color, dug in large quantities from the soil of Australia and New Zealand. It is a resinous exudation from the Kauri Spruce, *Agathis australis* Salisb. (*Dammaris australis* Lamb.), of the Fam. *Coniferæ,* but, as it first exudes and is found on the surface of the ground, it is not esteemed. The useful resin is a fossil deposit found especially in New Zealand swamps at depths of from 2 to 14 feet. The production of kauri is largely carried on under governmental supervision. The resin appears in pieces ranging in size from that of a hen's egg to a man's head, of a pale greenish-yellow color and with a balsamic odor. Large quantities are used in the arts, especially in the manufacture of linoleum. According to Tschirch and Niederstadt, it contains *kaurinic acid,* $C_{10}H_{16}O_2$, 1.5 per cent.; *a-* and *β-kaurolic acids,* $C_{12}H_{20}O_2$, 48 to 50 per cent.; *kaurinolic acid,* $C_{17}H_{34}O_2$, and *kauronolic acid,* $C_{12}H_{24}O_2$, together, 20 to 22 per cent. All these resin acids are soluble in solution of sodium hydroxide. *Baume Calédonien* consists of a solution of kauri gum in an equal weight of 90 per cent. alcohol. It has been used with alleged great success in the treatment of *wounds* and *ulcers,* of *eczema* and other skin affections, and as a substitute for collodion and the soluble sodium silicate. When applied to a well cleansed and dried wound it leaves a slight deposit of resin as a varnish, which is not affected by friction or contact with water.

The commercial product known as *Manila copal,* according to Tschirch and Koch, is derived from *Agathis Dammara* Rich. (*Dammora orientalis* Lamb.), a conifer. It consists chiefly of free amorphous resin acids, namely, *alpha-* and *beta-mancophalolic acid,* $C_{10}H_{18}O_2$ (about eighty per cent.), and contains besides about 12 per cent. of a resin, $C_{20}H_{32}O_2$, and about five per cent. of essential oil. The latter, when fresh, forms a liquid as clear as water, very mobile, having a pleasant odor, and the sp. gr. 0.840; it boils at from 165° to 170° C., and mixes in all proportions with alcohol, ether, chloroform and fatty oils. See also the article on *Copal.*

Kefir. *Kephyr. N. N. R.* 1924. (See also *Lactic Acid Therapy* and *Lac Fermentatum.*)—From time immemorial the Tartars and the Balkan peoples have employed as a food and beverage one or another form of fermented milk. The Tartars prepared from mare's milk a drink known as *koumiss* or *kumys.* This is prepared by the action of a peculiar ferment known as *kephir* (*kepir*) and called also by the Mohammedans "*the prophet's millet.*" In Western Europe mare's milk not being available, an imitation of kumys has been made from cow's milk, to which the term "*Kephir milk*" should be applied, limiting the word kumys to the genuine Tartar drink. The Armenians employed a fermented milk, *madzonn* or *matzoon*. *Giaourdi* is a fermented milk prepared in Greece from sheep and goat's milk with an enzyme obtained from fermented figs. The Bulgarians use a fermented milk known as *yoghourt* (*yaowite*). The Arabians have a fermented milk called *leben.*

The *kefir grains* (or seeds) are white, irregular, roundish bodies about the size of a walnut with a rough, ferruled surface, of gelatinous or, when dried, cartilaginous consistency. Despite considerable investigation, their composition is not yet definitely settled. They probably contain several micro-organisms as follows: (1) a yeast fungus which Spivak (*N. Y. M. J.*, 1896) believes identical with the ordinary yeast, *Saccharomyces cerevisiæ*, but which Beyerinck believes to be a distinct species, *S. kefir*, (2) *Bacillus Dispora Caucasica* (Kern) or *Bacillus Kephir* (Sorokin), (3) *Bacillus acidi lactici*, (4) other bacteria which are probably of little importance to the process of fermentation.
